8.4 That Memeticists Don't Say that People Have Memes Anyway, We Say that Memes Have People

Lynch (1996b) inverts the meme-host relation to give memes which have people, rather than the converse.

'In the area of population psychology and psychohistory, memetics achieves just such a paradigm shift by inverting an everyday question. Instead of asking how people acquire ideas, the new paradigm asks how ideas acquire people.'

This, however, does nothing to help. When does the meme 'Napoleon died in 1822' have me? Only when I am transmitting it? Or all the time, given that I transmitted it on one occasion and may or may not transmit it in the future?

8.5 That Memes are Only the Homoderivative Subset of Mnemon Replication Events

Although Lynch (1998) has mnemons of the type 'awareness of *x*' or 'belief in *x*', not all of these mnemons are memes in his system. Only homoderivative mnemons are memes. By homoderivative, Lynch means that they are produced by replication of the same mnemon in another individual. In Lynch's own words, it is: 'A memory item, or portion of an organism's neurally-stored information, identified using the abstraction system of the observer, whose instantiation depends critically on causation by prior instantiation of the same memory item in one or more organism's nervous systems.' By contrast, heteroderivative mnemons are somehow produced in response to an attempted but unsuccessful transmission of a different mnemon, or as I think Lynch might say, whose instantiation is not a consequence of any such causation. Lynch is therefore postulating that only a subset of Dawkins B memes should be considered as true

memes. But this is not a fixed subset, as mnemons can be *simultaneously* memes *and* not memes. For instance, in Lynch's system, whenever I utter the phrase 'Napoleon died in 1821' (N1821) to my student, the following events occur.

Two mnemons are involved. The first is the mnemon N1821, as a basic unit of information, and the second is 'belief in N1821'. Our mnemon, N1821, which I believe and therefore, Lynch would say, constitutes a mnemon 'belief in N1821', is a meme *only* if my student believes it, since only then does a homoderivative replication event take place. If I have a lecture theatre full of students of varying degrees of scepticism and gullibility, and I utter N1821 (which *I* believe), it is simultaneously a meme *and* not a meme depending on the belief reactions of the students. However, its alter ego, the simple mnemon 'awareness of the concept N1821' *is* always a meme, provided the students comprehend it, regardless of whether or not any of them believe it. Aside from the awkwardness of N1821 being simultaneously a meme and not a meme, the problem for any empirical memeticist is that we cannot observe if belief has been replicated or not, so we cannot in any case decide in Lynch's system if the mnemon 'belief in N1821' is a meme or not. Besides, Lynch's system still presents the same problems of defining when and how a mnemon is instantiated in its host. Since mnemons can only be inferred on the basis of behaviour or artefacts, adoption of these complicated neologisms does not clarify any of the issues raised here (and surely the last thing memetics needs is yet more neologisms). Lynch also presents 'a symbolic calculus of mnemon conjugations and replication events', but this is not usable in the elucidation of any of the problems here presented, since again the invalid assumptions are made at the outset that individuals *have* mnemons, and that belief states are transmissible mnemons.

8.6 That I Contradict Statements Made In My Earlier Work

This is true, so I ought to be specific about how much backtracking I wish to do. In Gatherer (1998), p.209-210), I state:

'Rather than mind viruses, religious memes, like scientific ones, may be considered as mind symbionts, replicating themselves through a positive contribution to the well-being of (most of) those who carry them.'

I am now considerably less comfortable with the idea of individuals *carrying* any memes. Religious beliefs may be beneficial to (most of) those who profess them, but this is a psychological phenomenon rather than a memetic one. The whole mind-virus/symbiont controversy is based on an incorrect meme-host duality, as described in the present article. I still stand by my view of religions as 'large, integrated complexes of memes' (Gatherer 1998, p.205), but I should now say that beliefs are not among those memes. The memes in question are the observable, copiable aspects of religion, such as prayers, rituals, artefacts, liturgies, dogmas etc. In an earlier article (Gatherer 1997b), I discuss the merits of memetic diversity, and the problems arising from its global depletion. At the time I intended beliefs to be considered as part of such memetic diversity. However, this argument loses no force even when belief is left out of the issue. In fact, that much was already implicit in the original. We may preserve the memes of indigenous cultures, their practices, artefacts and general way of life, but we cannot preserve

their beliefs. I can dress like an Amazonian shaman, dance like him and perform his rituals, but I *cannot*, try as I might, *believe* the same things as he does; belief is simply not transmissible. By the time I came to write Gatherer (1997c), I was already effectively considering memes as observable artefacts (music, in the context of that paper). I had not then consciously come to reject a mentalistic notion of memes, but perhaps the rigours of considering a real cultural system were beginning to push me in that direction.

9 And Finally....Yet Another Meme Definition

One who spends so much effort criticising the meme definitions of others, ought to present a clear target for his own critics. The following is therefore offered:

***Meme:** an observable cultural phenomenon, such as a behaviour, artefact or an objective piece of information, which is copied, imitated or learned, and thus may replicate within a cultural system. Objective information includes instructions, norms, rules, institutions and social practices provided they are observable.*

That will suffice for a bald definition. By way of supplementary clarification, one might say that this definition excludes behaviours which are genetically determined (which are left to the sociobiologists), although a behaviour which is genetically determined in one individual may be copied by another individual who is not so determined, and thus become a culturally propagated meme (eg. incest avoidance, see Durham 1991, Chapter 6). It also excludes those aspects of culture which are not observable, and not readily transmissible, such as beliefs (which are left to the cognitive psychologists). It also excludes behaviours which are learned via trial-and-error or Skinnerian reinforcement although, as above, once such behaviours are observable, they can be copied and thereby become memes. Individuals may be, and usually are, intimately involved in the production, transmission and copying of memes, but these memes cannot be said to belong to such individuals, or to parasitise such individuals.

I do not claim any originality for this definition, because it is essentially identical to that previously given by Benzon (1996):

'... I suggest that we regard the whole of physical culture as [memes]: the pots and knives, the looms and cured hides, the utterances and written words, the ploughshares and transistors, the songs and painted images, the tents and stone fortifications, the dances and sculpted figures, all of it. For these are the things which people exchange with one another, through which they interact with one another. They can be counted and classified and variously studied.'
(Benzon 1996, p.323)

One might ask: what difference would such a memetics have to already existing fields such as diffusion studies or social contagion theory? The answer would be: very little, except perhaps that a Darwinian streak would be more prominent; it would be an empirically-based evolutionary contagion/diffusion theory, which might *eventually* tell us something about the evolution of culture as a whole.

But this would be no bad thing. Memetics as it currently stands is a strange beast, an unrealistic psycho-epidemiology, laden with neologisms, neither theory of mind nor theory of culture. To make it into a science, we need to move forward into territory already occupied by diffusion sociologists and social psychologists. *We are not pioneers* (despite the 'new science of memetics' rhetoric that occasionally surfaces), but just *a new wave of settlers*. To survive in our new environment we need to learn from those who have been living there at least since the days of Gabriel Tarde at the turn of the century. The first step must be to shed the unnecessary baggage of 'thought contagion', 'memory abstractions' and meme-host duality. This is not just necessary in order to retain the goodwill and respect of our new neighbours, *but for the sake of intellectual survival*.

Acknowledgements

I thank the members of the Bristol Meme Lab for kindly inviting me to visit them, and for many helpful comments. Similar thanks go to Stephen Bentley and his evolutionary discussion group at University College London. My colleagues Nick Owen (Liverpool Institute of the Performing Arts) and Holly Smith (School of Human Sciences, Liverpool JMU) have also suffered having my ideas bounced off them. None of these people, of course, necessarily agree with any of the above.

THE CASE FOR COMMENTARY

By

Derek Gatherer

School of Biomolecular Sciences

Liverpool John Moores University, Byrom St., Liverpool L3 3AF

D.Gatherer@livjm.ac.uk

The article 'Why the Thought Contagion Metaphor is Retarding the Progress of Memetics' argues that the field of memetics took a wrong turning in the early 1980s, with the result that all subsequent memetic theorising has driven down the same blind alley. The wrong turning was to substitute the earlier, flexible definition of a meme (which in the article I term **Dawkins A**) with a far narrower and more specific definition as a unit of information in a mind or brain (termed **Dawkins B**).

Since science generally abhors vagueness and thrives on precise definitions, such a move naturally seemed like a step forward. In this case, however, it was counter-productive, since:

a) Direct observation was relegated to a subsidiary role, while inference and speculation took centre stage. The derivation of internal memes from behaviour relies on acts of the most naive inference. This is not the same situation as that of a classical geneticist of the early 20th century, since genes were not naively inferred from phenotypes, but were indirectly demonstrable as segregation ratios, patterns of independent assortment or linkage. There is no equivalent phenomenology in memetics. Internal memes are not even indirectly demonstrable. Their existence cannot be independently verified in any way.

b) Quantification became impossible. We cannot quantify any internal mental unit, and quantification is as essential as precise definitions (if not more so). While it is possible to quantify behaviour, either roughly in the field or more precisely in the laboratory, such quantification of behaviour does not translate into quantification of internal memes, unless the internal meme and the behaviour exist in a one-to-one correspondence. There is no evidence for this.

c) The theory lacks explanatory power. To say that behaviour can be explained in terms of something which cannot be observed is unhelpful. In any case, there is also no evidence that replication of behaviour is necessarily correlated with replication of internal mental states. We have no grounds for believing that thoughts are contagious, and such a view trivialises psychology.

d) Lynch's calculus of mnemon conjugations is incompatible with any present thinking in either cognitive sciences or linguistics. The picture of the mind as a stack of 'awareness of statement x' and 'belief in statement x' would require the mind to store language in a manner reminiscent of a computer RAM. Such possibilities were effectively excluded by Chomsky in the early 1950s. I should therefore like to ask the commentators if they consider 'internal' memetics to be still tenable in the light of these criticisms. If so, how do they believe it should be constituted as an experimental science (as opposed to a pseudoscience dealing in postulated unobservable entities,

where neither verification nor falsification are possible)? If the commentators agree with me that `internal' memetics is untenable, do they tend towards my quasi-behaviourist version of `external' memetics, or have they a third alternative?

**A PLEA FOR METHODOLOGICAL DARWINISM:
A COMMENTARY ON ROSE'S PAPER:
CONTROVERSIES IN MEME THEORY**

By

Derek Gatherer

School of Biomolecular Sciences, Liverpool John Moores University, Byrom St., Liverpool L3
3AF
D.Gatherer@livjm.ac.uk

*"We, alone on earth, can rebel against the tyranny of the selfish replicators."
(Dawkins 1978 [1976], p.215)*

Free will and intentionality have bedevilled philosophers for centuries. "*We have free will and there's an end on't*", declared Samuel Johnson in the 18th century. Others, from Johnson's contemporary the Marquis de Laplace to B.F. Skinner in the 20th century, have, for a range of different reasons, been less certain. A middle road is often taken, which allows for strong exogenous influences on human behaviour while retaining a fundamental bedrock of human autonomy. The trick, apparently, is to learn to exercise that autonomy. Thus for Herbert Marcuse and his fellow Frankfurt School Marxists, the workers labour not merely under physical and economic repression, but under the hypnotic sway of a cultural hegemony that convinces them that they are not really repressed. For Freud's heterodox disciple Wilhelm Reich, repression is not so much economic as sexual, and indoctrination of inhibitions takes place at an early age. Either way, the solution is to recognise the source of the cultural 'programming' and the reward for casting it off is freedom. Jean-Paul Sartre by contrast, in his early philosophy, leans towards the Johnsonian end of the spectrum. For the early Sartre, the Marxist and Freudian accounts of human behaviour sound more like excuses than explanations. We are always free to choose, whether we like it or not, and to fail to recognise that is to commit the only cardinal sin recognised by the existentialist, that of *mauvaise foi* (Sartre 1969 [1943]).

Recognition that genes may have phenotypic effects that are not always to the benefit of the individual organisms that contain them, presaged by J.B.S. Haldane but beginning rigorously with the work of W.D. Hamilton in the 1960s, led to the body of evidence summarised by Dawkins (1978 [1976]) in *The Selfish Gene*. Dawkins, of course, added the meme as a second, non-genetic, replicator. Just as some genes are beneficial to their hosts, while others are more concerned with propagating themselves at their hosts' expense, so too are memes arranged on a spectrum from the unreservedly wonderful (eg. science in Dawkins' estimation) to the truly parasitic. Dawkins' intellectual heritage owes more to Dr Johnson than to Marx, but his picture of religious memes as the ultimate 'mutually compatible gang of viruses' (Dawkins 1993) has distinct affinities with Louis Althusser's 'false consciousness' working in favour of a sinister status quo (Althusser 1977). Darwinian algorithms have replaced dialectic, but the call to arms is the same: it's time to rebel against the selfish replicators.

Dennett (1987, 1991) takes the meme theory a stage further. Now the meme is not seen merely as a replicator within consciousness, but as the essence of consciousness itself. Of course, Dennett does not intend that memes should be units of phenomenology - qualia are disqualified

in his theory - but that the illusion of consciousness is produced through the combined action of myriads of behavioural and abstract memes. The higher functions of consciousness, the ability to choose, the ability to exercise our freedom, the ability to design intentionally, thus no longer require a homuncular agent in the brain, no longer require a Sartrean *pour-soi* or a Johnsonian free will. We are after all automata, but of an infinitely more sophisticated kind than the Marquis de Laplace could ever have envisaged. Our consciousnesses are so Machiavellian that they can even fool us into believing that we have qualia, that we have intentionality, that we have freedom. Clearly, in this view rebellion against the selfish replicators is impossible. We are made of selfish replicators, they do not merely colonise our otherwise healthy minds. They are our minds, healthy or otherwise.

Against this, Anthony O'Hear (1997) maintains that there is nevertheless still a problem with our free will (illusion or not, it's still a factor in which memes get selected). O'Hear would accept Nick Rose's proposition that attribution of variation and selection of memes to conscious foresight does undermine the claim of memetics to be an evolutionary project. In reply to Rose's question - why do we need an evolutionary theory of culture at all? - O'Hear might reply that we don't need one and furthermore we should not concern ourselves with attempting to find one.

So we have Dennett in one corner, updating Laplace and Skinner to produce a non-homuncular, non-Cartesian theory of consciousness as grand illusion, and in the opposite corner we have Dr Johnson, Sartre and O'Hear, maintaining that we really are free come what may and that there is no way any Darwinian algorithm is going to straighten out that one. Somewhere in the middle we have Dawkins, the Freudians and the Marxists, acknowledging our capacity for freedom but pessimistic concerning its ability to resist the exogenous forces that dictate to it. Rose stands over on the Dennettian side, and naturally sees the others as fudging the task of explaining the mind in a mechanistic evolutionary manner. Rose is right, if Universal Darwinism is the game, they have given up on it.

I cannot claim to contribute anything novel to the debate concerning free will or intentionality, but I suggest that part of the problem lies in the tendency to see memetics as a theory of the mind. Dennett, of course, is primarily interested in the mind, and much of the recent resurgence of memetics is owing to his sponsorship. But memetics, both in Dawkins' original version (Dawkins 1978 [1976]) and in its treatment by Cavalli-Sforza and Feldman (1981), was originally a theory of culture couched in fairly materialist terms. If we adopt a population-level approach to culture, if we proceed from meme as behaviour, artefact or other materially identifiable unit straight up to whole culture as meme pool, skipping the grey and murky intervening level of individual human consciousnesses, then the problem, if not exactly solved, becomes less serious. I concede that those who believe in intentionality as a real thing, and not merely an illusion, may still protest that the origins of memetic novelty are therefore not random, that we have a spanner in the works of the Darwinian algorithm. Darwinism would seem to require that variation be randomly generated and not in some way directed towards some goal, otherwise the ghost of Lamarck intervenes. However, to this I would reply that we can only really address this possibility by empirical observation. Analysis of novel behaviours in the context of the cultural systems in which they appear is the only way to determine if the non-randomising effect of intentionality in individuals will be sufficient to destabilise the Darwinian algorithm as applied to the 'big picture' of culture.

I thus plead for a methodological Darwinism in cultural evolution rather than a theoretical one, just as I plead for a methodological behaviourism rather than a Skinnerian one. O'Hear may be right, perhaps intentionality does rig the jury where cultural novelty is concerned. However, the big picture may still nevertheless be amenable to Darwinian analysis. Only empirical studies can answer this question. So do we need an evolutionary theory of culture? Perhaps not, but I'm going to continue on the assumption that we do.

REPLY TO THE COMMENTARIES ON MY PAPER: “WHY THE THOUGHT CONTAGION METAPHOR IS RETARDING THE PROGRESS OF MEMETICS”

By

Derek Gatherer

D.Gatherer@organon.nhe.akzonobel.nl

Firstly I should like to thank all the contributors for taking the time to read my article and comment upon it. Secondly, I ought to apologise for the lateness of my reply. This is a consequence of my absence in South America for 6 weeks at the end of 1998, and also my abrupt and unexpected departure from academia at the beginning of February. Consequently I am still having problems with library access, and have been unable to do the reading required to address some of the points made by the commentators. Nevertheless, I hope I can use this opportunity to clarify a few ambiguities that have clearly arisen.

David Hales (1999) makes the point that the 'intentional stance' is a necessary feature of everyday life. I agree entirely, but I am unsure that this is really an argument against behaviourism in the laboratory or field. Dennett's work, such as the intentional stance, and (especially) his subsequent 'disqualification of qualia' are, as Dahlbom (1993) has pointed out, aspects of behaviourism in its modern guise. Behaviourism is not, contra Heylighen (1999), an outmoded school of psychology but one which continues to evolve and adapt to the changing empirical landscape. Dennett's work, including the 'intentional stance', is just one important manifestation of that process. The intentional stance is precisely that, a stance. It has much in common with what Paul Marsden has called the 'memetic stance'. In both cases we are required to analyse situations 'as if' intentions/memes (delete as applicable) were involved, and ask how such assumptions help to explain the behaviour we see. I would say that the intentional stance is best taken in what Hales (1999) calls 'its weakest form' as an 'instrumentalist device' - although I accept John Wilkins' (1999) caution that I should not rely overly on instrumentalism. Whether or not it also gives the user 'enhanced predictive power', as Hales says, is a matter for empirical demonstration. Hales (1999) holds out some hope yet for the Dawkins B model, in which case I suggest a further argument which may be used against it (Houghton's 'shopping list' thought experiment, see Houghton 1997, pp. 162-163). I can also point to the most recent reviews from those actually looking for memes in human brains. Their results are not encouraging to the Dawkins B school (Lounasmaa et al 1996, Gall et al. 1998).

Francis Heylighen (1999) correctly points out that a theory-free science would be scarcely scientific. My determination to throw out most of post-Dawkins B memetic theory may seem to give the impression that I am against theory in principle. It is true that I have no novel theory of my own to offer in its place, but I would insist that my own work is couched in the standard (neo-) Darwinian Theory which involves identification of variation, replication and selection. There are newer theories which may also be of assistance in the construction of a behaviourist memetics, for instance the recent work of Wallace et al (1996) and Wallace and Wallace (1998). Theoretical constructs are necessary, I agree. Our job is to find new ones that will succeed where older varieties have failed. Like most memeticists, I came to the subject through theoretical speculation, but I now see myself as a 'coal-face' empiricist. Coal-face workers are bound to

revolt occasionally against bad (theoretical) management. But that does not mean we are opposed to management in principle.

Heylighen (1999) refers to the interesting contagious suicide problem, and states that "*what was replicating was not the actual suicide behaviour, but the idea that suicide is a good way out of an apparently unsolvable problem*". I have to disagree with this. I fear it makes too many assumptions. Many of the people who succumb to the strange phenomenon of contagious suicide are precisely those who would seem to have the least reason to do so. 'Unsolvable problems' are rarely the issue. If they were, the phenomenon would scarcely be so macabre and fascinating, or so interesting a subject for memetics.

Paul Marsden (1999) suggests that the strategy should be a focus for memetic analysis. I am perfectly happy with strategies that can be analysed behaviourally. I have done a little empirical work on lecture attendance as a student learning strategy. In some cases, it seems to work quite well and in other cases does not seem to have any relevance to the postulated goal (see Gatherer and Manning 1998). Experimental design is difficult, and ethical considerations regarding students' careers do rather limit the extent to which the experimenter can manipulate the system. But I agree with Marsden, strategy-oriented memetics may represent the way forward. Hans-Cees Speel (1999) requests a clarification of my point regarding the meme-host duality. This is an important plank of my thesis, so I ought to try to improve on my original formulation, as follows.

Individuals have genes in the 'ordinary language' sense of the word 'have'. Molecular genetics has demonstrated that we do indeed have these genes in the same way that we have the grosser parts of our anatomy. The Dawkins B meme is also something which we could have in the same way. If there are replicating information structures in our brain, then the same ordinary language use of the word 'have' could apply to Dawkins B memes just as it does to genes. I would submit, however, that there are no such things. We could have Dawkins B memes, but we don't because there aren't any. Therefore, in ordinary language usage, we do not have Dawkins B memes.

What about Dawkins A memes? Well, these are a very different and much more heterogeneous class of entities, being behaviours and artefacts and all the other messy things that empirical work throws at us. Although there is another ordinary language use of the word 'have' which applies to artefacts, for instance I may have a remaindered copy of 'Thought Contagion', this is not the same sense in which I have my genes, or in which I could have the fictitious Dawkins B memes.

I speculate that there is perhaps a sense of unease among our non-Anglophone colleagues, concerning such fussiness about the use of words. It is true that ordinary language philosophy in the spirit of JL Austin is not something that has travelled well outside of the Anglo-American world. That honorary Anglo-American, Ludwig Wittgenstein, described ordinary language philosophy as a way of showing the fly out of the fly bottle. I maintain that the meme-host duality is a fly bottle in which the memetics movement has become trapped. Our escape from this particular trap also leads to the demonstration that we can have no true population memetics, as follows.

Population genetics is based conceptually on the assignment of genes to individuals, usually two alleles per locus in a diploid Mendelian population. Those individuals have those genes. They have them in the strong ordinary language sense of 'have'. This is crucial. If they ceased to have them in such a sense, population genetics would crumble; all the equations depend on the assignment of genes to individual members of the population. In order to have a population memetics, it would be necessary to assign Dawkins B memes to individuals with the same degree of rigour. But we can't. There are two reasons why not. The first is the trivial one, which is that there are no such things as Dawkins B memes. The second is exemplified in my 'Windsor knot' thought experiment, and also in Houghton's (1997) 'shopping list' thought experiment.

All we are left with is Dawkins A memes. These are infuriatingly transient entities which fail to satisfy the strong sense of the word 'have' which is necessary to a population science, be it population genetics or population memetics. Heylighen (1999) makes some additional point that genes can have multiple phenotypic effects, such as a feather gene whatever that may be, producing several hundred feathers. I do not think this is relevant. A feather gene may produce several hundred or thousand feathers, but they are all on the same individual. That individual has that feather gene, in the strong sense of the word. There is a definite relationship between the feather allele and the individual hosting it. How many feathers that gene produces on that individual is of no consequence to my argument.

This brings me on to another point, made by John Wilkins (1999) which is the hypothetical entity (HYPE) nature of the Dawkins B meme. HYPEs are often discovered to be real entities; that which begins as a convenient theoretical construct can often turn out to have a genuine reality. For instance in the pre-Watson/Crick era, genes were HYPEs. However, there is an important sense in which pre-Watson/Crick genes ('classical' genes we might say) were much less HYPE than Dawkins B memes. Wilkins alludes to 'Mendelian genes, observed by their effects'. They are of course observed by their effects, but not just by their effects. I well remember from my student days the long list of sceptical criteria which classical geneticists (my experience was with the Aspergillus school in Glasgow) applied to any claim for the discovery of a novel gene. A classical gene has to be true breeding, it has to demonstrate segregation in crosses, it has to consistently assort independently from, or map together with, other loci etc. The classical gene was not merely a HYPE lying behind the empirical reality of phenotype, but an empirical phenomenon in its own right, defined by all manner of rigorous criteria. The Dawkins B meme, by contrast, has no such criteria, no rigour of any description. It is simply a HYPE lying behind the empirical reality of behaviour.

Wilkins (1999) raises another interesting question: how, in a behaviourist framework can one distinguish between homology and analogy, eg. between little Charlie's accident and Prince Philip's butler? I cannot pretend to have an answer to this. However, I am consoled by the fact that it is equally difficult to distinguish between these things in genetic evolution, even at the molecular level.

Wilkins (1999) also refers to the informational aspects of memes. I think his argument here has affinities with a thought experiment presented to me by Sue Blackmore and friends at Meme Lab, which runs as follows: if I tell you a joke while I have a hoarse voice, you do not tell the joke to your friends using the same hoarse voice, or even using my normal voice. Rather you tell

the joke in your own normal voice. We are able to extract a certain informational content from a speech behaviour which does not involve all aspects of the behaviour.

Wilkins (1999) postulates a realm of 'culturally significant transmits' (in his Fig. 2) Having just about removed myself from the influence of Popper, I have to confess I feel a little frisson of fear at this spectre of World 3. Having said that, behaviourists as well, of course, have to come to terms with 'memes without a hosting subject' (to paraphrase Popper). Popper lurks behind so much of memetics, but his exact relationship to the discipline is still not completely defined. I hesitate to address the comments of Aaron Lynch (1999), for fear that I leave myself open to further accusations of willful misrepresentation. Lynch insinuates that my criticism of his work is religiously motivated. Elsewhere, referring to the change from Dawkins B in my earlier papers to my current behaviorist stance, he ruminates darkly "*Exactly what happened to change his mind is unclear*". I should have thought it was very clear - reflection on 20 years of internalist memetics persuaded me it was going nowhere. He also insinuates that I was '*recently still unaware of the evolutionary epidemiological ("thought contagion/mind virus") explanation for the prevailing forms of monotheism by natural selection*'. Alas, I was aware of them, but they are so vacuous as to be scarcely worthy of comment in a scholarly journal. Since Lynch insists, I deal with them below.

Lynch also repeats his peculiar allegation that I have misrepresented him, drawing attention to an 'if' which he claims that I have ignored, thus changing the sense of his argument. However, the 'if' in question makes no difference. Lynch's picture of menmons arranged ~PQ~TY etc is quite clearly a stack of memory bits, exactly like a computer RAM. His calculus of mnemon conjugations then deals with individuals as hosts of string of the said bits ~PQ~T~Y etc. Why he should now seek to deny this is unclear. It is in his paper.

Lynch also claims that I have a "*casual lack of understanding of the term infinite*". What can one say? This is nonsense. Of course I understand the meaning and use of the term infinite. And what is the basis for such a strange allegation? His subsequent sentences are unclear, but he appears to be arguing my case. It is precisely because as he says 'it is physically impossible for humans with finite brains to construct an infinite number of dates for Napoleon's death' that his calculus of mnemon instantiations is untenable, as developed in detail in my article.

Even more bizarrely, Lynch refers to my 'monotheism'. What monotheism? I am not a monotheist, or indeed a theist of any description. However, this outlandish ad hominem argument does present an opportunity to deal with Lynch's own specific theory concerning monotheism, which is that: 'In an ancient society, where people believed in numerous gods, a belief that there is only one God had a competitive propagation advantage - not as genetic information, but as mental information. It caused its hosts to devote all of their meme transmission efforts to just one god-meme, allowing this god-meme to out-propagate competing memes.' (Lynch 1998)

As with much of Lynch's work, it is difficult to know if this is a serious proposition or just some kind of witty self-parody. Unfortunately I must assume the former. If monotheism really requires less propagative effort than polytheism, and will out-compete polytheism on this basis, one must be able to explain why Christianity was the successful Trinitarian derivative of a not particularly

successful strictly monotheistic religion (Judaism). Christianity, with its almost incomprehensible concepts of 3-gods-in-1 and gods turning into lunchbox items, rapidly became even more polytheistic with the acquisition of a fourth member of the pantheon (the BVM) and a whole panoply of minor deities (the communion of saints). Monotheism, contra Lynch (1998) does not automatically outcompete polytheism, as the example of Christianity shows. Indeed, the incorporation of Roman polytheism in growing Christianity, taking it away from its monotheistic origins, was a crucial element in its spread. One wonders if Lynch thinks at all about his speculations before committing them to publication.

Similarly we have, concerning baseball 'Does internally stored information about numbers of players to recruit explain why baseball out-propagates tennis in the US? You have to read Lynch for yourself'. Rather than analyse such a laughable claim, I shall simply quote Caton (1997), who agrees with me that Lynch "*suppresses empirical psychology so that personal speculations may flourish.*"

MODELING THE EFFECTS OF MEMETIC TABOOS ON GENETIC HOMOSEXUALITY

By
Derek Gatherer
derek-gatherer@usa.net

Abstract

Simple computer simulations of the interaction of genetic factors and memetic taboos in human homosexuality are presented. These simulations clearly show that taboos can be important factors in the incidence of homosexuality under conditions of evolutionary equilibrium, for example states produced by heterozygote advantage. However, frequency-dependent taboos, i.e. taboos that are inversely proportional to the incidence of homosexuality, cannot produce the oscillating effect on gene frequencies predicted by Lynch (1999). Effective oscillation is only produced by rapid withdrawal and re-imposition of taboos in a non-frequency-dependent manner, and only under conditions where the equilibrium incidence of homosexuality is maintained by heterozygote advantage, or other positive selectional mechanism. Withdrawal and re-imposition of taboo under conditions where homosexuality is subject to negative selection pressure, produce only feeble pulses, and actually assist in the extinction of the trait from the population. Additionally it is shown that frequency-dependent taboos assist in a more rapid achievement of equilibrium levels, without oscillation, under conditions of heterozygote advantage. An attempt is made to relate the simulations to past and contemporary social conditions, concluding that it is impossible to decide which model best applies without accurate determination of realistic values for the parameters in the models. Some suggestions for empirical work of this sort are made.

Key words: gene-meme co-evolution, homosexuality, memetics

1 Introduction

Evidence for a genetic basis for homosexuality in humans remains controversial (Pillard and Weinrich 1986; Bailey and Pillard 1991; Bailey and Benishay 1993; Bailey et al 1993; Hamer et al 1993; Risch et al 1993; Haynes 1995; Hu et al 1995; Rice et al 1999). It is clear that psychological, sociological and environmental influences also play a part (e.g. Werner 1979). However it would be surprising if there were not at least some genetic predisposition, given the weight of evidence for biological contributory factors (e.g. LeVay 1991; Allen and Gorski 1992; Snyder et al 1994; Reite et al 1995; Swaab and Hofman 1995; Zhou et al 1995; Sanders and Wright 1997; McFadden and Pasanen 1999). Among the possible non-genetic influences may be counted the existence of taboos against homosexuality in many societies. It has been proposed that frequency-dependent taboos may interact with genetic influences to produce an oscillating frequency of homosexuality, specifically:

"In a nutshell, ... [the theory]... says that adherents of the taboo out-procreated more tolerant people over the course of many generations in ancient times, leading to increased prevalence of

the taboo. (This does not require anything like a perfect correlation between morality and behaviour, or a perfect child inculcation rate, but only enough to increase taboo prevalence by several percent per generation over hundreds of generations.) Then horizontal transmission kicked in as people maligned homosexuality to "prove" their adherence to the taboo. As the taboo becomes extremely widespread, most homosexuals live heterosexual lives, leading them to reproduce any genes involved. As these genes gain prevalence, the rate of taboo dropout increases. Gene carriers who have dropped the taboo are more sexually and socially motivated to spread acceptance of homosexuality than are non-gene carriers who drop the taboo. So the rising gene prevalence can lead to a self-sustained propagation of pro-gay memes. That, in turn, can lead to lower gene prevalence in the next generation, and even lower prevalence of pro-gay memes. All of this leads to potential fluctuations over long time spans." (Lynch 1999)

This paper investigates this hypothesis using a simple model incorporating Fisher's classic equations of natural selection, upon which is superimposed a model of a memetic taboo as a restriction on the freedom to openly practice a homosexual lifestyle. The taboo is assumed to be strictly memetic, i.e. there is no genetic predisposition to intolerance, and there is no tendency for individuals of any particular genotype to exhibit one meme as opposed to another, i.e., there is no gene-meme linkage disequilibrium (Laland 1992). Various computer simulations were scripted in Perl, and used to analyse the effects of taboos and heterozygote advantage on the incidence of genes predisposing to homosexuality. The Perl scripts are available on http://www.geocities.com/derek_gatherer/supp.htm.

2 Methods and results

There is no clear indication of the location in the human genome, of any genes predisposing to homosexuality. The best candidate is the tip of the long arm of the X chromosome, but the evidence for this is still not absolutely convincing (Hamer et al 1993, Hu et al 1995; Rice et al 1999). In the present paper, homosexuality is modelled as an autosomal recessive trait, primarily for ease of simulation.

2.1 Model of selection against homosexuality as an autosomal recessive trait

In this section the following assumptions are made:

- a) predisposition to homosexuality is a single-locus, biallelic autosomal recessive;
- b) heterozygotes are heterosexual;
- c) the homosexual phenotype results in a lower level of sexual reproduction than the heterosexual phenotype;
- d) a large population is modelled, in which there is no significant genetic drift, and no immigration of groups with different genetic compositions.

Following Fisher's classic model of selection against an autosomal recessive trait (given in Ayala and Kiger 1984), a hypothetical population can be modelled, in which a/a is the genotype of individuals predisposed to homosexuality, A/a is the genotype of heterozygous individuals, and

A/A are individuals carrying no copies of the gene predisposing to homosexuality. A small illustration follows of the way that selection pressures are calculated in the classic methodology. Following the tradition in classical genetics, these individuals A/A are referred to as the 'wild-type', and A as the 'wild-type allele'. H-W is the expected proportion of each genotype under the Hardy-Weinberg equilibrium.

	A/A	A/a	a/a
H-W	0.25	0.5	0.25
Parents	2500	5000	2500
Progeny	7500	15000	750
Av./indiv	3	3	0.3
Fitness	1	1	0.1
s	0	0	0.9

Table 1. H-W is the expected frequency of genotypes under the Hardy-Weinberg equilibrium, s is the selection pressure. 'Av./indiv.' Is the average number of progeny per individual

Table 1 shows an illustrative population of 10,000 individuals in an initial Hardy-Weinberg equilibrium. Thus, if q is frequency of the allele a predisposing to homosexuality and p is the frequency of the wild type allele A , and $p + q = 1$ (i.e. a biallelic locus), then the frequencies of our phenotypes are:

$$\begin{array}{ll} A/A & p^2 \\ A/a & 2pq \\ A/a & q^2 \end{array}$$

In table 1, $q = 0.5$, thus the proportions of $A/A:A/a:a/a$ are 1:2:1.

The population in Table 1 is growing rapidly, purely for illustrative purposes. The frequencies of the progeny in the next generation are counted. (The progeny of each male and female is counted separately, so each offspring is effectively counted twice - this however is of no bearing on the result, as the *relative* quantities of progeny are the important issue in the calculation of fitness and selective pressure).

In the example in Table 1 A/A and A/a individuals produce an average of 3 progeny each, but a/a individuals only produce 0.3 offspring per individual. Fitness (w) is the relative reproductive success of each genotype compared to the most successful genotype. By this criterion, genotypes A/A and A/a have fitness $w = 1$, and genotype a/a has fitness $w = 0.1$. Selection pressure, $s = 1 - w$, so for genotype a/a this is 0.9.

One may then proceed to Fisher's model of change in allele frequency per generation for a disadvantageous autosomal recessive trait (given in Ayala and Kiger 1984)

$$(1) \quad \Delta q = \frac{-spq^2}{1-sq^2}$$

2.2 Simulation 1: Effect of differing value of s on the incidence of homosexuality

The initial incidence of homosexuality in the population is taken to be 0.9, i.e. 90% of the population is homosexual. This kind of extreme *reductio ad absurdum* is used purely for the purposes of making the clearest illustration of the trends predicted by the model. Later, more realistic parameters are discussed. This simplest simulation in which negative selection pressure gradually eliminates a gene from a population, is, of course, trivially true from the viewpoint of geneticists. It is included however, in order that other readers may see the most basic framework of the Fisherian analysis.

5 different values of s are chosen ranging from 0.9 down to 0.1. The results are plotted below (Figure 1):

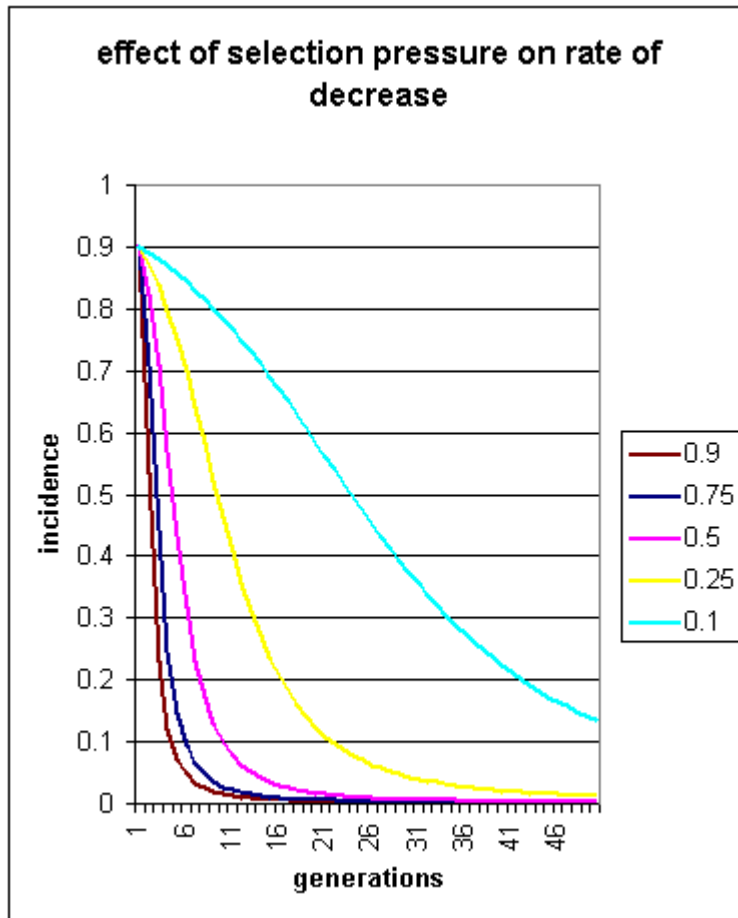

Figure 1: incidence of homosexuality plotted over 50 generations, at varying levels of s , from 0.1 to 0.9. s has an effect on the rate of decrease, but the overall trend is always downwards

It can be seen that in all cases, the incidence of homosexuality declines. At the highest value of s , 0.9, only 1.5% of the population is homosexual after 10 generations. Even at the relatively mild level of $s = 0.1$, corresponding to a reproductive deficiency of only 10% per generation, 10 generations produces a decline in homosexuality from 90% of the population to 78.4%.

It is thus clear that if homosexuality is due to recessive genetic factors, and if homosexuals are less successful at sexual reproduction than heterosexuals, (i.e. if $s > 0$, even by a small value), homosexuality will eventually disappear from the population (except for new mutations). This disappearance can be astonishingly rapid, e.g. at $s = 0.9$ homosexuality falls from 90% of the population to 23% in a mere 3 generations.

2.3 Simulation 2: Introduction of taboo

Let the taboo, b , be quantified as the proportion of homosexual individuals who lead heterosexual lives.

$$b = 1 - (h_{\text{vis}}/h_{\text{total}})$$

where h_{vis} are 'visible' homosexuals, leading openly homosexual lives and h_{total} is the total number of predisposed homosexuals of genotype a/a .

It is assumed that those individuals of genotype a/a who lead heterosexual lives have rates of sexual reproduction equal to individuals of genotypes A/A and A/a .

Therefore b reduces s as follows:

$$s_{\text{tab}} = s(1-b)$$

where s_{tab} is the selection pressure in the presence of taboo b , and s is the selection pressure in the absence of any taboo.

s_{tab} can then be substituted for s in equation (1) above.

Which can also be reexpressed using Laland's (1992) nomenclature, as:

$$(2) \quad \Delta q = \frac{-r_2 s p q^2}{1 - r_2 s q^2}$$

where there are two cultural traits, r_1 and r_2 , and only the phenogentotype a/a . r_2 is deleterious. b is kept constant by requiring that Laland's (1992) expression for the horizontal transmission of a meme within a single generation, result in no change, i.e.. that $N_d(i)$ should always equal $N_d(i-1)$:

$$(3) \quad N_d(i) = \frac{N_e}{1 + \left(\frac{N_e}{N_o} - 1 \right) e^{-\ln(1-a)^i}}$$

where N_e is the total population, N_0 is the initial population exhibiting the meme, $N_a(i)$ is the population exhibiting the meme after i cultural generations (and there are i cultural generations per biological generation), and a is the rate at which the meme tends to be replicated horizontally within that cultural generation. N_e and N_0 can be assumed to be constants for the present purposes, so the crucial variables are i , which is arbitrarily set at 1, and a . Therefore simply by adjusting a , the taboo, b , can be kept constant within the population. Adjustments in which b is allowed to change owing to changing values of a , are of course, possible. However, b is kept constant again here for the purposes of simplicity.

Let s and b both be 0.9. Let the initial frequency of individuals of genotype a/a be 0.9 (again an absurdly high starting value is taken for the purposes of illustration).

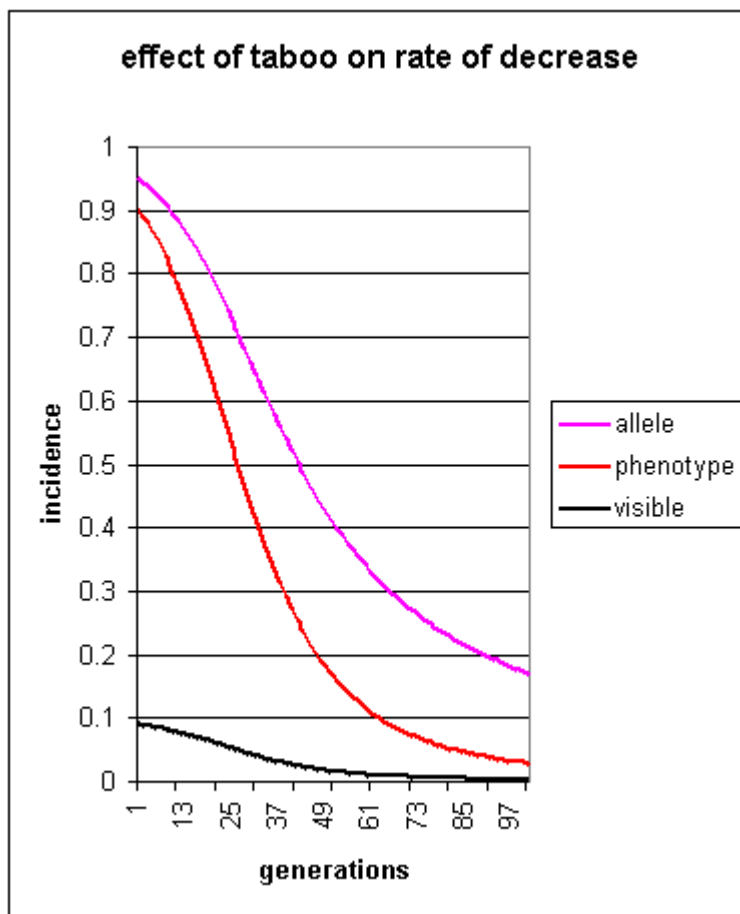

Figure 2: Frequencies of alleles predisposing to homosexuality, the predisposed homosexual phenotype and visible homosexuality, plotted over 100 generations under conditions of taboo, $b = 0.9$

As can be seen, under conditions of taboo of 0.9 the number of visible homosexuals in the population is initially only 9%. The frequency of visible homosexuality, and of predisposed individuals a/a , falls. After 28 generations the number of visible homosexuals has fallen to 4.5%. Under such circumstances, it can be seen that taboos alone cannot act to increase or even maintain levels of homosexuality, but can only slow the rate at which it decreases (as is generally predicted for any situation of this kind by Laland 1992, Figure 2 of that article).

Lynch (1999) states "*As the taboo becomes extremely widespread, most homosexuals live heterosexual lives, leading them to reproduce any genes involved. As these genes gain prevalence...*". It can be seen from the above simulation that this is impossible. A taboo of 0.9 has been chosen, and yet genes predisposing to homosexuality still decrease rapidly. They certainly do not 'gain prevalence'.

2.4 Simulation 3: Fluctuating levels of taboo

Let initial levels of homosexuality be 0.9, as before. Let the taboo initially be 0.9, but then be decreased to 0.1 after 3 generations, simulating a major social attitude change. Let the taboo increase again to 0.9 after a further 3 generations, and return again to 0.1 after 3 more etc. Again this is a crude simplification of what in real life are bound to be complex political, social and anthropological factors affecting taboos. Once more, these assumptions are made purely for the purposes of clarity in the simulation. Since it is clear from simulation 2, that a steady taboo will not make genes predisposing to homosexuality 'gain prevalence', the purpose here is to investigate what effect a fluctuating taboo will have.

This situation is produced by again manipulating Laland's equation (3) above; such that a is alternately extremely high for the taboo, then extremely high for the non-taboo in 3-generational blocks. Why a might vary in such a way is irrelevant to present purposes.

The withdrawal and imposition of the taboo in 3-generation cycles produces a faster overall decline than when the taboo is constant at 0.9. Compare Figure 2 in simulation 2, where $s = 0.9$, $b = 0.9$, in which the same interval of 12 generations only produces a decline in visible homosexuality from 9% to 7.7%, with Figure 3 above, in which the withdrawal and reintroduction of the taboo every 3rd generation produces a reduction in 12 generations from 9% to 5.4%

Whenever the taboo is withdrawn, as in generations 4 and 10, there is an increase in visible homosexuality. However, the second sudden increase is much lighter than the first, and further pulses of this sort, such as that caused by the release of the taboo in generation 16, are scarcely visible.

2.5 Simulation 4: Incorporating heterozygote advantage

Among the most potent forces for the maintenance of allele frequencies in populations is heterozygote advantage, or heterosis. This phenomenon is established as an important factor in sickle cell anaemia, since heterozygotes are malaria resistant (reviewed by Durham 1996). There is some evidence for cholera resistance in cystic fibrosis heterozygotes (Gabriel et al 1994), and for ochratoxin resistance in phenylketonuria heterozygotes (Woolf 1986). Tuberculosis resistance has also been hypothesised in Tay-Sachs disease heterozygotes (see Spyropoulos *et al* 1981 and Diamond 1988 for both sides of the debate). Possible heterozygote advantage in homosexuality is discussed by Ruse (1981).

Again following Fisher (as reproduced in Ayala and Kiger 1984), it is possible to produce an equation for the change in allele frequency in the case of heterozygote advantage. In this situation, there is a selection pressure against a/a , s as before, but also a selection pressure t against wild-type homozygotes A/A .

Figure 3: Incidence of allele predisposed to homosexuality, the predisposed phenotype and visible homosexuality over 20 generations under conditions where the taboo is withdrawn and imposed at 3 generation intervals.

$$(4) \quad \Delta q = \frac{pq(tp - sq)}{1 - tp^2 - sq^2}$$

Under such conditions, an equilibrium level is achieved at:

$$(5) \quad q = \frac{t}{s+t}$$

Let s be 0.9 as before.

Let t be 0.1 This means that wild-type homozygotes A/A have a reproductive or survival deficit of 10% relative to heterozygotes.

Let the taboo, $b = 0.9$.

Let the initial frequency of homosexuality in this case be 0.1.

Let these conditions apply for 150 generations, after which the taboo decreases to $b = 0.5$ (again by manipulating the variable a in Laland's equation (3) above to suit our purposes)

This population initially has a level of visible homosexuality of 1%, but the heterozygote advantage allows this to increase to 2.8% over 95 generations. This is virtually an equilibrium level, which is sustained for a further 55 generations. When the taboo is suddenly diminished after 150 generations, the level of visible homosexuality peaks suddenly to 14% of the population. However, with b now at 0.5, s_{tab} is now 0.45. The population begins to move towards a new equilibrium level of visible homosexuality of approx 1.7% achieved after a further 43 or so generations.

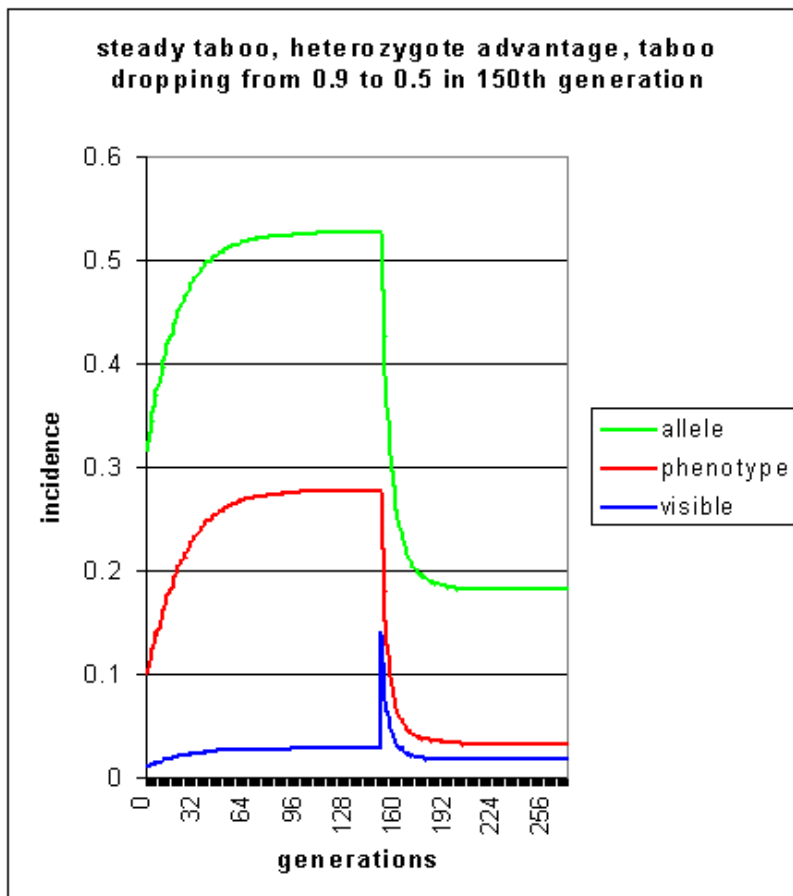

Figure 4: Incidence of allele predisposing to homosexuality, the homosexuality phenotype and visible homosexuality, under conditions of heterozygote advantage, over 300 generations. The taboo drops from 0.9 to 0.5 in generation 150

Heterozygote advantage thus allows homosexuality to achieve equilibrium levels, whereas simulations 1-3 above all result in downward trends. As was pointed out before in simulation 2, this result is textbook material for geneticists. However, it is included here in order that non-genetical readers may clearly see the effects of heterozygote advantage on a deleterious allele.

2.6 Simulation 5: Heterozygote advantage with fluctuating taboo

Let the heterozygote advantage be heavy, $t = 0.5$. Let s again be 0.9, and the initial incidence of homosexuality be 0.9. The taboo, b , is initially 0.9 and switches between 0.9 and 0.1 every third generation until the 25th generation when it returns permanently to $b = 0.9$. Once again, it is not suggested that such arbitrary fluctuations are in any way a realistic portrayal of any current or past political situation. The purpose is merely to illustrate how heterozygote advantage may interact with fluctuating taboos.

Figure 5: Incidence of allele predisposing to homosexuality, the homosexually predisposed phenotype and visible homosexuality, under conditions of heterozygote advantage, over 50 generations. The taboo switches between 0.9 and 0.1 every third generation until the 25th generation when it returns permanently to taboo = 0.9

Again the alternating release and reimposition of the taboo cause pulses in the level of visible homosexuality. These pulses are much stronger than when there is no heterozygote advantage (see simulation 3), and when the taboo is permanently reapplied, the level of visible homosexuality stabilises at around 7% in the 50th or so generation. Only an excessively implausible level of heterozygote advantage, at $t = 0.5$, can produce such a striking effect.

2.7 Simulation 6: Introducing a frequency-dependent taboo

The frequency-dependent taboo is a taboo which diminishes as the frequency of homosexual individuals rises (*"the rising gene prevalence can lead to a self-sustained propagation of pro-gay memes"* Lynch 1999). Note that this is not 'Frequency-Dependence at the Memetic Level' (Laland 1992), since the frequency of the taboo is dependent on the frequency of the genetically determined phenotype, not on the frequency of other memes.

Therefore in each generation, the frequency dependent taboo b_{fd}

- $b_{fd} = 1 - q^2$
- and the selection pressure, s_{fd} is then
- $s_{fd} = s_{init} (1 - b_{fd})$
- where s_{init} is the selection pressure in the absence of a frequency-dependent taboo.

Let us compare 2 populations, both starting with incidences of homosexuality of 0.9, and starting with $s = 0.9$, but one population having a steady taboo of 0.9, and the other exhibiting a frequency-dependent taboo, where the b_{fd} changes in each generation as above.

The steady taboo population has a slow decrease in the levels of visible homosexuality from 9% to 4.5% in 23 generations. The frequency-dependent taboo population initially has high levels of visible homosexuality and consequently a low taboo. However, as levels of visible homosexuality drop dramatically under the influence of $s = 0.9$ in the absence of heterozygote advantage, the taboo climbs, and in generation 20 exceeds the level in population 1. Such high levels of taboo, achieving 0.95 by generation 48, means that visible homosexuality is virtually eliminated from population 2. This shows that frequency-dependent taboos do not produce the oscillating effect that Lynch (1999) claims. On the contrary, a taboo of this sort would speed the eventual elimination of the genes predisposing to homosexuality from the population.

2.8 Simulation 7: Frequency-dependent taboo combined with heterozygote advantage

Let us compare 2 populations as above, but incorporating heterozygote advantage. Both populations have $s = 0.9$, and $t = 0.1$. One population has a constant taboo 0.9 and the other has a frequency dependent taboo.

Figure 6: Incidence of visible homosexuality and level of taboo, over 50 generations. 'Steady pop.' is the frequency of visible homosexuality in the population with the steady taboo. 'F.d. pop.' is the frequency of visible homosexuality in the population with the frequency-dependent taboo

The population with the frequency -dependent taboo rapidly achieves an equilibrium level after only 12 generations, whereas the population with constant taboo takes 50 generations. Note that there are no pulses in the frequency of visible homosexuality. This demonstrates that neither constant nor frequency-dependent taboos can produce the oscillating effect predicted by Lynch (1999).

3 Discussion

The above models have dealt with extreme and implausible values of incidence and selection pressure, simply in order to make the trends on the graphs more obvious. In this section an attempt to simulate a realistic set of variables will be attempted.

The fundamental assumption of this paper is that the predisposition to homosexuality is primarily genetic, but that the behavioural expression of that predisposition is determined by memetic factors such as taboos. These models therefore only represent a limited subset of possible

models. For instance one might construct a model in which homosexuality is entirely culturally determined, or in which homosexuality is related to environmental factors which are neither

Figure 7: Incidence of allele predisposing to homosexuality, the homosexually-disposed phenotype and visible homosexuality, under conditions of heterozygote advantage, over 50 generations. The taboo is constant.

genetic nor cultural. Nevertheless, there are compelling reasons to suggest that the gene-meme interactionist approach is at least plausible, given the weight of empirical research that has accumulated on the biological basis of homosexuality and on how cultural attitudes affect it.

Exact quantification of the incidence of male homosexuality in the past and present is a highly controversial area (Gonsiorek et al 1985, Lhomond 1993; Weinrich et al 1993), but an estimate of a current incidence of visible homosexuality of some 5% seems not unreasonable (Johnson 1994). Waugh et al (2000)'s intriguing 'lost letter' experiment suggests that the general public are only 49% as likely to behave altruistically to an overtly homosexual as to a non-homosexual person, which means that one might measure taboos accordingly. This would bring the score of *a/a* individuals up to 10% of the population which is still within some of the upper-end estimates (e.g. Thin and Smith 1976). It is clear that visible homosexuality has recently increased, at least in Western (post)-industrialised societies. Downey (1980) surveyed over 5 generations, and concluded that homosexuality has increased overall among males but that it has decreased among married males, over this time. The decrease in the number of married homosexual males

is strongly suggestive of a decrease in taboo. However, the *overall* increase may suggest that there has *also* been an actual increase in the frequency of *a/a*, perhaps due to a heterozygote

Figure 8: Incidence of allele predisposing to homosexuality, the homosexually-disposed phenotype and visible homosexuality under conditions of heterozygote advantage over 15 generations. The taboo is frequency-dependent.

advantage in the process of achieving equilibrium (e.g. simulation 4). It is possible that the release of previous taboos has been superimposed onto this. If taboos are frequency-dependent (Lynch 1999), then an increase in numbers of *a/a* individuals due to sex-specific advantage, or a heterozygote advantage in the process of achieving equilibrium, would also trigger decrease in the taboo.

It is clear from the simulations presented here that frequency-dependent taboos do not result in the oscillations predicted by Lynch (1999). By contrast, oscillations can only be produced by imposition and release of *frequency-independent* taboos, and *even then* only when phenomena such as heterozygote advantage or sex-specific selection are *also* operating.

Despite the difficulty of disentangling genetic and cultural factors in the short-term, it may be possible to gather some empirical facts that might help in choosing the most likely model. The models for heterozygote advantage and sex-specific advantage (the latter not explicitly discussed

here, but see Ruse 1981; Gallup and Suarez 1983; Dickemann M 1995; Miller 2000) require a fairly extreme set of parameters in order for them to be able to sustain high levels of homosexuality in populations. In the case of the heterozygote advantage model presented here, A/a individuals should have a greater reproductive success. A/a individuals represent two-thirds of the siblings of a/a individuals. If the current level of homosexuality is approximately 10%, i.e. $q^2 = 0.1$ (Thin and Smith 1976), and homosexuals have currently half the level of reproductive success of heterosexual males, i.e. $s = 0.5$ (this is pure conjecture - this parameter is one which needs empirical research), then the heterozygote equilibrium equation (equation 5, above) trivially solves to:

$$t = 0.24$$

Therefore, if the above estimates for q and s are correct, one requires $t = 0.24$ to sustain this in a system of heterozygote advantage. This implies that the A/a siblings of homosexuals have a strong reproductive/survival advantage over wild-type A/A individuals, of some 24%. The magnitude of the required t is therefore scarcely plausible, and one might be tempted to exclude the heterozygote advantage hypothesis on this basis. However, empirical data is need to ascertain if the above estimates for q and (especially) s are accurate. The 1994 National Survey of Sexual Attitudes and Lifestyle (Johnson 1994) estimated the incidence of homosexuality to be between 1.1% and 6.4% of men and 0.4% and 3.4% of women. If the most conservative estimate of 1.1% is taken, then t under heterozygote advantage where s remains 0.5, becomes $(0.10 \times 0.5)/0.9 = 0.06$, which is perhaps a more plausible value. If s is overestimated, then t reduces even further.

A 1970 survey (Fay et al 1989) placed the level of homosexual contact in the previous 12 month period as being some 1.6 to 2.0% of males. This gives an upper bound to q of 0.14. Furthermore, half of these males were found to be 'currently or previously married'. If we assume these males to have been equally reproductive as heterosexual men within their marriages, and if we assume never-married homosexual males to be non-reproductive, then we have $s = 0.5$. If we assume that non-reproductive homosexuality is predominantly male in its expression, then s reduces further to 0.25. We can then estimate t at $(0.14 \times 0.25)/0.86 = 0.04$. Heterozygote advantage need only be 4% if these values are accurate.

Furthermore, it is clear that although heterozygote advantage can (at least theoretically) sustain levels of homosexuality, and female-specific selection is even capable of increasing it, both of these mechanisms are unstable and vulnerable to sudden fluctuations in taboo (but *not* to frequency-dependent taboos). It is also clear that taboos alone in the absence of a positive selective mechanism such as heterozygote advantage, are insufficient to account for oscillating patterns in visible homosexuality. For instance compare simulations 2 and 3 with simulation 5. Simulation 5 has a strong oscillation *only* because there is *also* strong heterozygote advantage in the system.

One must be careful to distinguish current selective pressures from those operating in the past. It is possible that genes predisposing to homosexuality were elevated in the past through heterozygote advantage or female-specific selection, but that those selective pressures no longer apply. Therefore genes predisposing to homosexuality would now be in the model described in simulation 1, and be in a steady decline. The apparent 20th century increase in visible

homosexuality (Downey 1980) might just be a blip caused by a release in a taboo, which will be followed by a greater decrease in future generations. Alternatively, there may be selective mechanisms, such as heterozygote advantage or female-specific selection which are still in operation.

In summary, it is not possible to make accurate predictions concerning the application of these models to the real world without data concerning the reproductive success of siblings of homosexual males, and indeed of homosexuals themselves. If such data could be obtained, an estimate could be made for the parameters of the heterozygote advantage and female-specific advantage models. If either of these models is found to be plausible in view of this empirical data, estimates could be made for future levels of homosexuality subject to any fluctuations caused by changes in taboo which, as shown, are at their most important when strong biological selection is occurring.

If the empirical data does not support either of the strong selection models above, it must be concluded that visible homosexuality will decline. On the other hand, it may be that gene-meme interaction models of the sort presented here, miss some crucial environmental, psychological or sociological element that can explain why homosexuality is maintained even when gene-meme analysis might suggest it should not be.

THE SPREAD OF IRRATIONAL BEHAVIORS BY CONTAGION: AN AGENT MICRO-SIMULATION

By
Derek Gatherer
gatherer@biotech.ufl.org

Abstract

A micro-simulation is described, for rational and irrational strategies in human mating behaviour. The spread of irrational behaviour through a population from a single initial individual, the 'contagionist paradigm', is shown to be highly unlikely in most realistic circumstances. An exception to this rule is shown to be where the 'self-fulfilling prophecy' phenomenon is exhibited, i.e. the irrational meme affects the outcome of the mating. Additionally, where the irrational strategy, under conditions of self-fulfilling prophecy, is allowed to co-exist with a rational strategy (i.e. a strategy based on factual information), both can proceed to fixation, resulting in a population of individuals exhibiting both rational and irrational memes simultaneously. However, where successful pairs are removed from the population, there is a tendency for neither behaviour to persist. Maintenance of either behaviour in the population under circumstances of removal of successful pairs requires a cultural information system, i.e. one where a common pool of information may be accessed without a requirement for contagion. This implies that contagionist explanations of culture may be strictly limited in their application. Some attempt is then made to generalise the conclusions to financial systems.

1 Introduction

Human behaviour, at both the individual and social levels, is often apparently inexplicable. By contrast, the behaviour of software agents is, by definition, determined by their programmer, at the individual level. Nevertheless, at the social level, collections of software agents may behave as surprisingly as their real world counterparts. The appeal of agent-based social simulation is that one may design agents, of varying degrees of simplicity, that, when allowed to interact with each other, reproduce some of the identifiable behaviour of real human social systems. Some of the more puzzling aspects of human social systems may then be illuminated in the light of the computer simulation.

This paper investigates an agent population exhibiting two kinds of behaviour:

- Rational - defined as behaviour based on factual information, that maximizes the long-term material welfare of the agent, and
- Irrational - defined as behaviour based on incorrect premises, that is at best neutral to that agent's interests, and in some cases potentially detrimental.

In a simulation, it may be decided with certainty what constitutes 'factual information' and the best interests of the agent. In real life, of course, these can be more difficult to determine with

any reliability. It should also be stated that rationality in real organisms is a complex function that requires sophisticated cognitive functions. The agents described here have no AI component, but merely a series of rule-based functions. A considerable literature exists on the circumstances in which maladaptive, or apparently maladaptive, traits may become prevalent in human populations (e.g. Boyd & Richerson 1985, Durham 1991, Blackmore 1999). In this paper, the behaviours designated 'rational' and 'irrational' do correspond in many ways to 'adaptive' and 'maladaptive', respectively. However, the terminology 'rational' and 'irrational' is preferred since the 'irrational' behaviour in this simulation may coincidentally act in the agent's interests, and therefore is not always maladaptive.

These two kinds of behaviour are replicated in 2 ways:

- Contagion - where behaviour can only be copied directly from one agent to another via social contact (simple 'echo' contagion of the behavioural variety - Levy & Nail 1993; those authors' requirement that there should be non-intentionality is not relevant to software objects).
- Via a common pool of cultural information - an agent can select a behaviour from a set of social norms, without coming into direct contact with another individual exhibiting that behaviour.

The essential concern of this paper is related to that of Doran (1998), in that an effort is made to produce mass behaviour arising from a set of simple behavioural rules. Another methodological inspiration is Ophir (1998), in that pairing events within the agent population are followed by the execution of a variety of calculations affecting the subsequent state of the agents. The agents are reflex agents, as defined by Doran (1998), in that they have attributes which are modifiable according to a set of 'condition-action rules', and also trigger actions that modify the attributes of other agents. The model presented is, in Edmonds' (1998) terms, an 'abstract, forward' model, in that the interest lies in what kinds of unpredicted group phenomena may emerge out of strictly regimented individual behaviours.

The system simulated is that of human mate pairing. It is clear from biological studies that many species are very selective in mate choice, and that there may also be vigorous competition between individuals for mates. As Darwin (1872) recognised, these two factors have resulted in the phenomenon of sexual selection for a wide variety of traits in species ranging from insects to mammals. In some species, mate choice behaviour also has a cultural dimension which may amplify, or conflict with, any underlying innate biological tendencies (Wade & Pruett-Jones 1990; Laland 1994; Freeberg *et al* 1999). The simulation presented here attempts to dissect how a 'rational' mating behaviour, arbitrarily taken to be selection of a mate of same status as oneself, conflicts with an 'irrational' mating behaviour, for instance the use of astrology to select a mate. Note that such 'astrological' behaviour need not necessarily always be maladaptive, since a good mate may coincidentally be chosen. It is, however, always 'irrational' regardless of its adaptiveness. Although astrology is apparently believed by 25% of US adults (Blackmore 1999, p184), it may not necessarily figure very prominently in real human partner choice (but perhaps in other aspects of reproduction, see Goodkind 1993). However, the example is given merely to contrast irrational and rational memes in a simple contagion-based agent-pair interaction system.

Generally similar dynamics may occur wherever agents are exchanging information repeatedly in a closed system. Additionally, it should be pointed out that the mated pairs are not engaged in reproduction, or even necessarily in any physical copulation, but rather in partner choice for potential reproduction. In other words, this model takes place within a single generation. Moreover, no genetic components are envisaged, and the behaviours are taken to be totally cultural. Finally, the population is not spatially segmented, and any individual can potentially mate with any other of the opposite sex. Ways in which the model could be expanded to incorporate a combination of genetics, multiple generations, and spatial heterogeneity are considered in the discussion.

2 Methods

The agents have the following attributes:

- Gender - male or female
- Status - high or low
- 'Star sign' - A or B
- Seek status information, i.e. act 'rationally' - yes or no
- Seek astrology information, i.e. act 'irrationally' - yes or no

The status and astrology attributes (4 and 5) are thus different memes and not mutually exclusive 'allomemes' (Durham 1991). With 5 binary attributes, there are 32 different potential types of agent in the population, that is 16 different types for each gender. Since all pairings in all simulations are between members of opposite genders, there are 120 possible kinds of pairings, i.e. $n(n-1)/2$, for which rules need to be constructed. Some of the preliminary simulations only use a subset of the attributes and have very simple rules. The patience of the reader is requested for the apparent triviality of the first few simulations, as they are designed to clarify the basic dynamics of the system. From simulation 3 onwards, the system becomes increasingly complicated, as more attributes and complex rules of interaction are progressively applied.

Gender, status and 'star sign' (attributes 1 -3) are considered fixed for any individual and cannot be changed. The behavioural states (attributes 4 and 5) relating to status and astrology may be changed under certain circumstances, representing a behavioural change in that agent. A 'yes' state for astrology means that the individual will seek to ascertain the star sign of the other individual. Likewise a 'yes' state for status results in behaviour to determine the status of the potential partner. The status-'yes' state is 'rational' in that status objectively influences the likelihood of success of the pairing (in the simulation, whether or not it does so in real life is quite another matter - see Brown *et al* 1988; Pizzari 2001). By contrast, the astrology-'yes' state is 'irrational' in that star sign has no objective effect on success (see Goodkind 1993, for an empirical example of how astrology may influence human reproductive behaviour).

Agents seek a mate at random from among the opposite sex in the population (as in Ophir 1998). The outcome of the mating (successful or unsuccessful) is determined by a combination of random chance, a background a priori likelihood of success, and various rules dependent on the types of agent involved. Having mated every individual in the population, the cycle repeats. Each iteration, the proportions of the population exhibiting the enquiry behaviours, i.e. the 'yes' states,

for status (rational) and star sign (irrational) are recorded. In some later simulations, successfully mated pairs are withdrawn from the mating pool and replaced with naïve individuals, as would be the case if mated pairs were to concentrate on reproduction and cease to look for further partners

Each simulation is produced using Perl scripts which, along with the full list of rules used in the more advanced simulations, are available from http://www.geocities.com/derek_gatherer/supp.htm.

3 Results

3.1 Simulation 1 - Highly contagious irrational behaviour in a highly susceptible population

The population is initialised with an equal number of individuals of each gender, each of which has randomly assigned status and star signs. Initially, all individuals are in the 'no' state for both behaviours. In this first simulation, a single individual is released into the population, exhibiting the 'yes' state for the irrational behaviour. A single simple rule is made that individuals only convert from 'no' to 'yes', and never in the reverse direction (in other words, this is the 'biased cultural transmission' of Takahasi 1998, 1999; or the 'cultural selection' of Cavalli-Sforza & Feldman 1981). As might be expected, under such a rule, the 'irrational' behaviour spreads rapidly throughout the population, essentially doubling in frequency for the first six cycles of pairing. After that point, its rate of increase slows a little as 'yes' individuals become more likely to encounter prospective partners who are already 'yes' in phenotype. In 3 simulations conducted in a population of 500 individuals, the entire population exhibits the irrational behaviour by cycle 12 in all 3 cases (data not shown). The dynamics are precisely the same as those of a highly infectious, incurable, sexually transmitted disease in a promiscuous population with no immunity. The total takeover of a population by a behaviour is called 'fixation', borrowed from population genetics - the opposite state being more obviously termed 'extinction'. The sigmoid curve of uncontrollable epidemic spread from a single individual to encompass the entire population is referred to here as the 'contagionist paradigm', and has been a regular feature of models of social processes at least as far back as Rashevsky (1949).

3.2 Simulation 2 - Contagious irrational behaviour with poorer replication rates

Let the irrational behaviour now depend on an element of chance in its replication. Once again the population is seeded with a single individual exhibiting the irrational behaviour. With lower chances of replication at any particular pairing event, the progress to fixation is delayed. However, since an individual, once exhibiting the irrational behaviour, is permanently in that state, eventual fixation is inevitable, even when transmission rates are very low.

Figure 1: Spread of a contagious trait introduced by a single agent into a population of 500 agents, at differing values of probability of transmission per contact, p . Where $p = 1$, i.e. the trait is always transmitted, it approximately doubles every iteration, and a population of 500 is almost always fixed by generation 12. These S-shaped curves represent the most trivial case of contagion, and are presented as a reference point for the curves in the subsequent simulations.

Although these curves are sometimes fairly flat, their shape is still sigmoid, and the 'contagionist paradigm' still applies. The only variable is whether the contagion is slow or fast. For instance in Fig.1, for $p = 0.1$, i.e. 10% chance of transmission per contact, it still takes 45 iterations for 20% of the population to have been infected. Thus, for cases of 'biased transmission'/ 'cultural selection', the contagiousness of a trait is not important to the eventual outcome, *ceteris paribus*. It is however, precisely this *ceteris paribus* assumption that is violated in all but the most trivial cases.

3.3 Simulation 3 - Contagious irrational behaviour with possibility of loss of irrational behaviour

Let the 'no' state for the irrational behaviour now also be transmissible. This means that in any pairing event, it is possible that individuals exhibiting the irrational behaviour may be converted to the rational behaviour. Here, the analogy with an infectious disease begins to break down, as contact between two individuals is as likely to 'cure' the one as 'infect' the other, at $p = 0.5$. A better analogy is to the random drift of a rare neutral allele frequency in a genetic system (Kimura & Ohta 1978, Kimura 1979). It is clear that under such circumstances, with two mutually exclusive behaviours vying for predominance in the population, the eventual victor will be the one with the greater tendency to convert the other. This is merely a confirmation of intuition, but it is perhaps less intuitive that a corollary of this is that, at $p = 0.5$, about half of novel contagious behaviours will face immediate extinction in the first generation. In order to illustrate the 'random walk' tendencies of the population under such circumstances, the simulation is started with equal numbers of 'yes' and 'no' individuals. The conversion likelihood is equal in both directions, and 1000 iterations are used. Of 5 populations of 500 individuals

beginning with 50% in each behavioural category, after 1000 iterations, 3 of the 5 populations have become fixed for the irrational behaviour and 2 have lost the irrational behaviour entirely.

Figure 2: 5 runs of a simulation in which the likelihood of conversion to a trait and conversion away from a trait are equal in each contact. In a population of 500, each starting with 250 individuals exhibiting the trait, 3 populations become fixed for the trait (blue, brown and turquoise) and the trait becomes extinct in 2 (green and pink). These are the most trivial examples of random walks, and like the S-shaped curves in Figure 1 are given for the purposes of reference.

Random walks are totally random, by definition, but may appear directional. Take for example the pink population in Fig. 2. After a period of quasi-periodic movement upwards, it suddenly turns and declines to zero. As this is an agent simulation, it is known that this is simply a random walk. However, an empirical worker approaching evidence in the other direction might easily conclude, wrongly, that there must be non-random influences on the trend. In a random walk, at $p = 0.5$ as given here, any trajectory is equally likely and the odds of any trajectory occurring are 0.5^n (i.e. p^n) for any particular trajectory of n steps. Since n is 1000 in simulation 3, there are approximately 10^{301} different possible trajectories, all equally likely, and each of which has an approximate probability of 10^{-301} . Over an infinite number of n , all trajectories will eventually terminate in fixation or extinction, with equal probability (Kimura & Ohta 1978, Kimura 1979). The sensitivity of such a situation to variation in p may be illustrated by considering what happens when p deviates from 0.5. Effectively, even small deviations away from 0.5 will pull the random walk rapidly to fixation or extinction.

Figure 2b: 5 runs of a simulation in which the likelihood of conversion to a trait and conversion away from a trait are equal in each contact. Again a population of 500 is used, starting with 250 individuals exhibiting the trait. Varying values of p , the probability of conversion to the trait, are given.

The rapidity of fixation and extinction is almost too fast to see over a timescale of 1000 iterations in Fig. 2b, so the early stages of the 5 simulations are shown again in Fig. 2c. Where $p \leq 0.4$ the trait barely survives 20 generations.

Figure 2c: The early stages of the simulations given in Fig. 2b above.

In general, the probability of a random walk, where p is not equal to 0.5 are $p^n + (1-p)^m$, where n is the number of incremental turns and m is the number of decremental turns. Therefore where p is not equal to 0.5, not all walks are equally probable, and the walks are quasi-random. This much is trivial, once again, but illustrates how easily cultural traits may exhibit chaotic

dynamics, especially if p is variable from generation to generation (dependent perhaps on other cultural factors). Under such circumstances, a predictive memetics would become virtually impossible, as cultural traits would swing wildly in frequency with apparently no rationale (perhaps a familiar scenario for empirical observers of culture). However, the situation does become more predictable as other factors are added to the simulation.

3.4 Simulation 4 - Making contagion dependent on the outcome of an event

So far, the irrational behaviour considered has been purely (and arbitrarily) contagious. Now a complication is introduced in that propagation of the irrational contagious behaviour depends on the perceived success of the mating by the pair involved. As described above, the population is divided into two arbitrary star signs. These are random labels with no function other than to divide the population into two random groups. Therefore any behaviour based on such divisions is by definition irrational, for example, the discussion of star sign with prospective partner. See Lindeman (1998) and Delfabbro & Winefield (2000), for some real life examples of irrationality in event interpretation.

Let the outcome of pairings in each iteration be recorded. Let also the chance of success in each pairing be s ($0 \leq s \leq 1$), the a priori success probability. A random number generator is used to generate a number between 0 and 1. If this random number is less than s , the pairing is deemed to have been successful. The following rules then apply:

If an 'astrological' individual pairs with a 'non-astrological' individual, and they are of divergent star signs, and the pairing is unsuccessful, the 'non-astrological' individual will convert to 'astrological' (because that is what the irrational hypothesis predicts, and spurious 'evidence' has apparently been provided).

If an 'astrological' individual pairs with a 'non-astrological' individual, and they are of divergent star signs, but the pairing is successful, the converse will ensue, i.e. the 'astrological' individual will convert to 'non-astrological' (because the irrational hypothesis has been falsified in this instance).

If an 'astrological' individual pairs with a 'non-astrological' individual, and they are of compatible star signs, and the pairing is successful, the 'non-astrological' individual will convert to 'astrological' (again because the irrational hypothesis has been spuriously 'verified').
If an 'astrological' individual pairs with a 'non-astrological' individual, and they are of compatible star signs, but the pairing is unsuccessful, the 'astrological' individual will convert to 'non-astrological' (because the irrational hypothesis has been falsified in this instance).

In other words, the outcome of the event will either be as predicted by the irrational individual or will not be so. The success or failure of the prediction determines the likelihood that one or the other individual will be converted to the behaviour pattern of the other. Note that pairings between two irrational, or two rational, individuals are not considered, as contact is required with an individual of the opposite behavioural type in order to produce behavioural modification. This is what is meant by a purely 'contagionist' mechanism, since contact between individuals is required for 'transmission' of behaviour.

Under such circumstances, it is again, as in simulation 3 above, virtually impossible for the irrational behaviour to colonise the population from a single individual. That is because the rules above are balanced, i.e. the number of events causing a conversion in one direction is equal to the number of events causing conversion in the opposite direction (rules 1 & 3 versus 2 & 4). As in the previous simulation, 5 populations are allowed to run for 1000 iterations with the initial frequency of the irrational behaviour at 50%. The chance of success for each pairing is also set at 50%.

Figure 3: 5 populations of 500 individuals, with initially 250 individuals exhibiting the irrational behaviour, and the transmission of the behaviour dependent on the outcome of pairings. Although the dynamics of this simulation are strictly rule-based, and those of simulation 3 dependent on binomial chance, the population trajectories produced by the two systems are indistinguishable.

3.5 Simulation 5 - Introducing the 'self-fulfilling prophecy'

The above example demonstrates that an irrational behaviour, even when based on 'evidence', is likely to follow a random walk within a population. Such a randomly walking trait is very unlikely to be able to colonise a population if there is initially only a single individual manifesting it. However, in simulation 3 above, it is assumed that the success or otherwise of every pairing was due to random chance. On the basis of this random chance, various rules determined the tendency of individuals to convert from one behaviour to the other. Let it now be imagined that the irrational behaviour affects the outcome of the mating (see Downey *et al* 1998 for a real-life example). The rules remain the same, but likelihood of success of a pairing is not equal for all pairs. If those individuals enquiring about the star sign of a prospective partner are less likely to have a successful pairing with individuals of incompatible star signs, and more likely to have successful pairing with those of compatible star signs, then this constitutes a 'self-fulfilling prophecy'.

Bias is defined as the extent to which astrology will interfere with the potential success of a relationship on a scale of 0 to 1, where the pair has incongruent star signs, and one or both of the

pair exhibit the astrology behaviour. This is programmed in the following manner. The a priori likelihood of success of a relationship is s , and bias is b , both are between zero and 1, and both are set in advance. A random number generator is again used to generate a number between zero and 1. Without bias, if that random number is less than s , the pairing is successful. With bias, b is subtracted from s . This reduces the likelihood that the random number will be less than s , and thereby 'loads the dice' against success. Where the pair have congruent star signs, and one or both of the pair exhibit the astrology behaviour, bias acts in the other direction, to increase the chance of success. This is programmed by adding b to s , rather than subtracting it as above, and therefore increasing the likelihood of success. Where $b-s$ is less than zero, the relationship is doomed to failure, regardless of the number produced by the random number generator. Likewise where $b+s$ is greater than one, the relationship is guaranteed to succeed. Where $b = 0.5$, populations run to fixation fairly smoothly for most values of s , provided the novel irrational meme can survive the first few iterations. This 'self-fulfilling prophecy' thus changes the irrational behaviour from a randomly walking trait into a colonizing one. The 'contagionist paradigm' of steady sigmoid curves, reappears.

Figure 4: An irrational trait originating in a single individual, colonising a population of 500, running to fixation in under 25 generations in 3 separate runs (red, green and blue). 5 runs of this simulation were performed, of which the other 2 resulted in immediate extinction of the trait at the first iteration. This is clearly an S-shaped curve, demonstrating that, once the novel meme has survived the first few iterations, the 'self-fulfilling prophecy' mechanism turns a random walk into an irresistible tendency. Parameters were $s=0.5$, $b=0.3$.

3.6 Simulation 6 - Introducing rational behaviour

Up to now, only the presence or absence of the irrational astrology-based behaviour has been considered. Now, let individuals also assess potential partners according to the rational criterion of 'status'. It is unimportant how this is defined, except that it is necessary that this be a genuine factor contributing to the success of pairings. Whereas the success of pairings of partners of differing or compatible astrological sign was purely a function of chance alone, or chance coupled to the 'self-fulfilling prophecy' phenomenon, the success of pairings of different status

groups has a fixed contribution to overall pairing success, independent of star sign or any behaviours. Greater pairing success for compatible status groups is therefore objectively true. That is why the status behaviour is regarded as rational.

Status effects can co-exist with irrational bias effects. In the interaction of the 2 strategies, the following general rules apply. The full set of precise rules is available on http://www.geocities.com/derek_gatherer/supp.htm.

- The status of paired agents is compared.
- The star sign of paired agents is compared.
- The rational and irrational behaviours for the paired agents are compared.
- If status is compatible, a priori likelihood of success is doubled (irrespective of whether or not either agent is rational)
- If at least one agent is irrational, the 'self-fulfilling prophecy' phenomenon interferes with the a priori likelihood of success up or down, accordingly.
- The success of the pairing is determined, using the random number generator.
- Based on success or failure, the agent states for the rational and irrational behaviours are altered.
- However, behaviours only change if an agent is paired with an agent exhibiting the appropriate behaviour (contagion still rigidly applied).

These rules allows both rational behaviour (relating to status) and irrational behaviour (relating to star sign) to enter the population. The two are not mutually exclusive and therefore separate memes rather than 'allomemes' (Durham 1991). Which meme propagates faster depends on the relative degrees of bias (the motor of the self-fulfilling prophecy phenomenon for irrational behaviour) and objective status-related increase in the likelihood of successful pairing. Indeed where a priori likelihood of success, s , is low and bias, b , is high, the rational behaviour tends to extinction.

Figure 5: Progress to fixation or decline to extinction of rational behaviour under varying conditions of 'self-fulfilling prophecy' bias, b , from 0.6 to 1, with an a priori likelihood of success of pairings of $s = 0.5$. In all runs, the irrational behaviour ran to fixation in 10 iterations.

3.7 Simulation 7 - Giving agents the benefit of experience

The previous simulations 3 to 6, have assumed that conversion events are dependent on the success of immediately preceding pairings. Perhaps more realistically in terms of human society, individuals will withhold judgment until several experiences have accumulated. Let the agents now have a threshold, t . Experiences liable to cause conversion to rationality or irrationality are accumulated, and the appropriate conversion takes place when the threshold is exceeded. The experience counter is then reset to zero. In other words, at a threshold of, say, 3, an agent will convert to rational behaviour only after 3 appropriate contributory experiences.

This decreases the volatility of the system, and promotes the settling of the population into a stable state. The equilibrium position is determined by the relative values of s and b , and the speed with which it is obtained is dependent on the threshold for conversion, t .

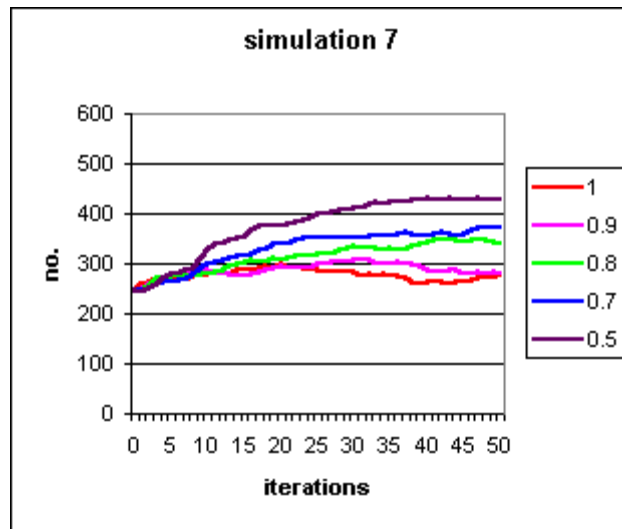

Figure 6: Progress of rational behaviour in the population under the same conditions as in figure 5 above (s constant at 0.5 and b run at 0.5 to 1), but with a threshold of 3 introduced. This delays fixation of rational behaviour under conditions of low bias, but also prevents its immediate extinction under conditions of high bias.

3.8 Simulation 8 - Removing successful pairs

All the previous simulations recycle the same individuals in a vulgar imitation of Schnitzler (1982). If successful pairs no longer seek further mates, as seems more realistic in human terms, let successful pairs now be replaced in the population by naïve individuals. Note that this is done based on simulation 6 - with possibility of individual expressing both rational and irrational attitudes, and without allowing any accounting of previous experience (naïve individuals have, by definition, no experience).

Where the a priori likelihood of success, s , is high, individuals are removed so rapidly from the population that neither the rational nor irrational behaviour is very persistent. Lowering s to 0.01,

and with high self-fulfilling prophecy bias, \mathbf{b} , it is possible to retain them for some longer time. However, the influx of new individuals wins out eventually.

Figure 7: Replacement of successful pairs with naïve individuals rapidly removes both behaviours, rational and irrational, from the population. Compare with Figure 4. The same parameters are used, $\mathbf{s} = 0.5$, $\mathbf{b} = 0.3$, which would normally generate a powerful "self-fulfilling prophecy" for the fixation of irrational behaviour. However, here the arrival of waves of naïve agents overwhelms the capacity of the contagion system.

3.9 Simulation 9 - Removing successful pairs from a population with memory

Simulation 7 showed that allowing agents the benefit of experience before changing strategy, caused changes to be subdued, both up and down. Simulation 8 showed that removal of successful pairs extinguishes both behaviours. This simulation combines 7 and 8 to see if memory can maintain the behaviours in such a population. However, the dynamics are the same as in simulation 8 (data not shown). This is only to be expected, as when individuals rely on their own experience, but cannot share it with the rest of the population, that experience is no longer available when the individual leaves the population.

3.10 Simulation 10 - Introducing a communal cultural information pool influencing conversion decisions

All previous simulations 1 to 9 have only allowed individuals to change their behaviour based on the behaviour of individuals with whom they come in contact. These models have thus been strictly contagionist models. Let the individuals now draw on a communal store of previous experience. This communal reference is built by recording the successes of pairings of different types. This is slightly different to simulation 8, in that there individuals were allowed to make decisions on the basis of their own experience only. Now recourse is permitted to knowledge of the experiences of other individuals. Individuals can convert without contact with another individual, if the cultural assessment is that rational or irrational behaviour is correct. This is similar, but not exactly identical to, the 'conformist transmission' of Henrich & Boyd (1998).

Thus rules 7 and 8 from simulation 6, above, are now altered to:

- Based on success or failure, a contribution to the communal information pool is made. The agent states for the rational and irrational behaviours are still altered in the usual way if an agent is paired with an agent exhibiting the appropriate behaviour.
- 8. But now additionally, behaviours can change even if an agent is not paired with an agent exhibiting the appropriate behaviour, subject to consulting the communal information pool for the latest consensus.

Thus the communal information pool does not replace contagion, but supplements it. This simulates an element of 'persuasion'. Agents still convert under the influence of other agents, both rationally and irrationally, if conditions are correct. However, where no persuasion is exercised, agents can still alter their behaviour if conditions are correct, and the cultural norm suggests they should. (Perhaps this violates Levy & Nail (1993)'s requirement for an absence of intentionality in a true contagion system, but I am unsure of what intentionality means in terms of software agents.)

This helps to maintain steady random walks very near the starting values, after an initial movement upwards or downwards (dependent on starting parameters) as the contagion effect begins, before the communal information pool helps to correct it.

Figure 8: Non-contagion-dependent cultural system. The self-fulfilling prophecy maintains some degree of irrationality, but the ability of agents to convert away from irrationality without contact with a rational agent prevents it from running to fixation. Again, $s=0.5$, $b=0.3$.

Note that in Fig.8 the starting parameters are $s=0.5$, $b=0.3$. By reference to Fig. 5, it can be seen that these would normally cause both memes to run to fixation. This is indeed the initial tendency (note the initial rapid upsurge in both blue and red lines), but the communal information then begins to pull the meme frequencies down towards a quasi-random walk around an equilibrium level.

3.11 Simulation 11- Cultural information pool with replacement of successful pairs

This is a combination of simulation 10 with simulation 8. In simulation 8 both behaviours were lost as naïve individuals took over the system. However, with the common cultural information pool, the behaviours persist.

Figure 9: Same conditions as simulation 10, but allowing replacement of successful pairs. The initial dip is caused by the arrival of the first set of naïve agents in the first cycle or so before the cultural system has adequate data concerning the likely success of various pairs.

As in simulation 10, the cultural pool requires a few iterations to establish its influence, this time after a very short initial spell (almost invisible on Fig. 9) where the downward tendency of simulation 8 is repeated. This precipitate drop recovers almost immediately as the common cultural pool begins to exert its influence.

4 Discussion

The main conclusions of the paper are that:

- The 'contagionist paradigm', i.e. the common sigmoid curve representation of a memetic epidemic, is a very special case, requiring a fairly contrived set of system parameters in order to be produced.
- The 'random walk', i.e. an apparently stochastic meandering of meme frequency over time, is the more likely situation, even when the underlying parameters are far from random - a frequent variation is a pseudo-random walk around an equilibrium level.
- A population with a high turnover of agents (and hence a high proportion of naïve agents at any one given time) cannot maintain either of the described behaviours, rational or irrational, i.e. those meme frequencies drop to zero, without recourse to the use of a cultural information pool.

Many additional variables could be added to the simulation. For instance, Ophir (1998) gives his agents age attributes, mates them at age 30, and has them expire at a random age between 60 and 100, after producing a single family of progeny. This allows discrete iterations to be replaced with more realistic overlapping generations. However, Ophir's agents are monogamous, and reproduce only once, the emphasis of Ophir's work being the distribution of economic resources rather than mate pairing behaviour. Also, Pearson & Boudarel (2001) have recently devised a matrix based system for agent pair interactions, which could be incorporated into the pairing process described here.

The strictly contagionist person-to-person replication of both the rational and irrational behaviour is shown by simulation 8 to be unstable in the face of removal of individuals from the population. Indeed, even when all individuals are retained in the population, irrational behaviour requires the 'self-fulfilling prophecy' phenomenon to spread through the population, as illustrated in the difference between simulations 4 and 5. Self-fulfilling prophecies have been empirically demonstrated in human mate pairing (involving 'rejection-sensitivity' rather than astrology, but the basic principle is the same - see Downey *et al* 1998).

The only way to maintain the irrational behaviour in the population in the face of high levels of replacement is to use some kind of common information pool system. This, however, requires that the agents choose to refer to the information system for guidance. If, for some reason, the population in simulation 11 neglects to maintain the information system, the dynamics of simulation 8 will begin to take over and both memes will slide towards extinction.

It is clear that a 'random walk' pattern of meme incidence over the iterations is more common than the 'contagionist paradigm' sigmoid curve, which only occurs in rather 'pure' situations.

Random walk-like effects may be genuinely random because of the stochastic nature of the system (simulation 3), because of balanced rules in a deterministic system (simulation 4), or be anchored pseudo-random walks because of fluctuations around an equilibrium (simulations 10 and 11). Good 'epidemiological' sigmoid curves in culture seem to require either arbitrary contagiousness (simulations 1 and 2), or a powerful selective force (the unopposed self-fulfilling prophecy of simulation 5). Some aspects of human life may be arbitrarily contagious, for example crowd hysteria (see reviews by Levy & Nail 1993; Marsden 1998). Several authors have worked within the 'contagionist paradigm', producing models of traits that spread in an epidemic manner. For instance, Takahasi (1998, 1999) refers to 'biased cultural transmission', Cavalli-Sforza and Feldman (1984) to 'cultural selection', and Sperber (1985, 1996) to the 'epidemiology of representations'. In these cases, it is taken for granted that the epidemic trait is either arbitrarily contagious or, in the case of Cavalli-Sforza and Feldman's 'cultural selection', that some powerful, and usually unspecified, psychological factor is promoting the spread of the trait. The self-fulfilling prophecy phenomenon of simulation 5 would presumably therefore be a case of 'cultural selection'. Another example might be 'prestige-based transmission' (Heinrich 2001) where certain individuals are far more widely copied than others, or 'emotional selection' (Heath *et al* 2001). Blackmore (1999) gives extensive further examples. Cavalli-Sforza and Feldman (1984) also refer to 'natural selection' on culture, where a cultural trait spreads through genuine adaptiveness in the absence of either arbitrary 'biased cultural transmission' or psychological 'cultural selection'. Powerful natural selective forces of this kind do indeed also

operate in culture, resulting in some sigmoid incidence curves for possession of, in modern times, mobile phones and other useful paraphernalia (Rogers 1995), or, in the Bronze Age, for bronze knives (Renfrew 1987). Hewlett and Cavalli-Sforza (1983) describe an epidemic spread of the use of the crossbow among Pygmies, conferring a great hunting advantage over the traditional bow and arrow.

Granted that cultural epidemics can, in theory, occur where there is natural or cultural selection (and certainly do occur for cases of natural selection), the question here is: to what extent could the contagionist paradigm be applied to (non-hysterical) irrationality? If most irrationality is disadvantageous (and therefore unlikely to be 'naturally selected', *sensu* Cavalli-Sforza & Feldman, as an adaptation), and it is not the result of hysteria (and therefore not likely to have greatly biased transmission over a short time period), and the human society concerned has ample recourse to a pool of experience of previous members, then the spread of irrationality in an epidemic manner would seem to be unlikely. The contagionist paradigm therefore seems to be an inadequate model for the long term persistence of irrational behaviour in human populations.

For instance, in a stock market system, agents could predict the future price of shares, and then bid for them irrationally (perhaps again based on astrology) or rationally (based on profit indicators). If the purchase of shares causes their price to be elevated, this constitutes a kind of 'self-fulfilling prophecy' phenomenon. This would tend to result in irrational bidding spreading throughout the entire investment community. The fact that this does not happen too often, is perhaps due to there being a well established communal information pool about the success of various previous investments, on which current investment decisions can be based. As in simulation 10, this would prevent even a strong 'self-fulfilling prophecy' of irrational share inflation from taking over entirely. Interestingly, Caginalp et al (2001) have identified lack of open factual information as a contributory element in 'bubbles' created during lab simulations of stock market trading. Such a situation would promote information exchange on a person to person basis and therefore lead to a greater susceptibility to contagion effects. Study of real markets has also led to the conclusion that the "level and nature of information available to dealers, and social communication networks" are important (reviewed in Marsden 1998, section 2). Empirical data shows that random walking does tend to predominate over long periods of time (Malkiel 1985). It is also interesting that although the common information pool helps to prevent irrationality running to fixation, it does not eliminate it. Just as evolution in financial markets does not lead to maximal market efficiency (Frank 1999), evolution in the mating game, or in any other area of human conduct, does not lead to maximal rationality. Henrich (2001b) presents an interesting example of the persistence of bottle-feeding in parts of the world where breast-feeding would result in lower infant mortality. One might also cite Rogers and Shoemaker's classic example of the determination of Peruvian villagers not to boil drinking water despite extensive health education and the established use of boiling for other food purposes (Rogers & Shoemaker 1972), or recent discussions of 'altruistic punishment' (Fehr & Gächter 2002) and the revival of the 'tragedy of the commons' debate (Ostrom *et al.* 1999, Henrich *et al.* 2001a). Henrich (2001b) finds that the persistence of maladaptive behaviour is most likely when: a) there is high probability that environmental information is inconclusive, and b) there is biased transmission of the maladaptive trait. This is entirely consonant with the simulations presented here. Interestingly and rather controversially, Henrich goes a step further and suggests that even adaptive traits require biased transmission in order to produce S-shaped

curves. This is a radical departure from the fundamental theoretical observation that natural selection of an advantageous trait is analogous in form to an epidemic, and produces an S-shaped curve (Fisher 1930). It is not appropriate to discuss this any further here other than to note that the present observations concerning the cultural information pool and the relative rarity of situations in which the contagionist paradigm applies, are consonant with the first part of Henrich's (2001b) thesis.

One point not covered in the simulations is the issue of spatial heterogeneity within the population. The simulations could be modified to give each individual a geographical location. Partner choice, and the extent of the cultural information pool, could thus be limited by geographical isolation. One might also permit the high status individuals greater geographical mobility than those of the low status. Multi-generational effects might allow some of the successfully mated individuals to produce offspring for reintroduction into the population at a later date. Incorporation of a genetic component might also be permitted, with some individuals being inherently more or less sceptical than others.

In summary, the contagionist paradigm is a special case scenario, only applicable to situations of:

- hysteria (Levy and Nail 1993),
- strong psychological distortion of transmission mechanisms (Cavalli-Sforza & Feldman 1981; Takahasi 1998, 1999), or
- powerful natural selection of an advantageous cultural trait (Cavalli-Sforza & Feldman 1981).

According to Henrich (2001b), the last of these three may also be suspect unless 2) also applies. Since 1) is rare, and 2) is often difficult to identify empirically (and in the worst cases is often no more than a post hoc explanation when no other can be found), it is submitted that contagionism has limited range as an explanatory tool of human culture.

FINDING A NICHE FOR MEMETICS IN THE 21ST CENTURY

By
Derek Gatherer
dgatherer@talk21.com

Many scientific disciplines have a ‘paradigmatic experiment’, a simple example of how the discipline is applied to a problem. Usually, the paradigmatic experiment is like a light that, if switched on, suddenly illuminates the rest of the field. Mendel’s pea crosses are the paradigmatic experiment for classical genetics. Sometimes, for disciplines where direct experimentation is a little harder, there is not so much a paradigmatic experiment as a paradigmatic example. For instance, the body of data relating to the distribution of sickle cell anemia is a paradigmatic example of the process of molecular evolution in human populations. Such paradigmatic instances are often found in textbooks, and with good reason, given the purpose of textbooks. Sometimes they also constitute the founding experiment in the field, but they need not do so; Mendel’s pea crosses were the founding work in genetics, but the sickle cell anemia story only gradually emerged from a large body of research on biochemical variation in human populations.

So what is the paradigmatic example in memetics? My own favourite is the ‘homebodies vs. the hellraisers’ model used as an introductory vehicle by Boyd & Richerson (1985). Homebodies raise large families of more homebodies. Hellraisers by contrast, tend to have fewer progeny, themselves also of a hellraising tendency. The hellraisers would be heading straight for the evolutionary graveyard, if it were not for one factor: put a homebody and a hellraiser together for any length of time, and the homebody can convert into a hellraiser. Thus, depending on the frequency and strength of social interaction, and the relative reproductive differential of the two groups, hellraising can persist in an often fragile equilibrium.

This simple model is attractive because it encapsulates so many of the themes of the memetic approach to cultural evolution. Notice that the nature of the tendency to homeliness or hellraising is left open. It is possible to conceive at least part of the model in genetic terms: each group has progeny of its own kind because of an innate disposition. Alternatively, one might see homeliness or hellraising as purely cultural attributes, in which case the tendency of progeny to acquire the same phenotype as their parents is merely due to prolonged contact. What is certain is that the conversion of homebodies into hellraisers must be purely cultural. Thus the model contains what Cavalli-Sforza & Feldman (1981) defined as ‘horizontal’ and ‘vertical’ transmission of traits. The unidirectional nature of the horizontal transmission also illustrates ‘cultural selection’. The greater fecundity of homebodies illustrates ‘natural selection’. By subtly varying the parameters of each of these processes, Boyd & Richerson (1985) display several equilibrium states.

I call this a paradigmatic example, because if one can fully understand this simple model, and appreciate its sensitivity to parameter changes, the essence of most current work in cultural evolution and gene-culture co-evolution can be grasped. The problems also become apparent. Just what is the relevance of such a model to the real world? For those who take a co-

evolutionary approach, i.e., those who try to see such problems as involving genes as well as memes, there remains the problem of how, at a mechanistic level, genes influence behaviour. Evolutionary biology and sociobiology are not yet fully integrated into molecular genetics. To express it in Aristotelian terms, genes may, for some, provide a convincing 'material cause' for behaviour, but they have not yet been directly demonstrated to provide an 'efficient cause'. Even for those who are happy to see the example as one that involves exclusively cultural traits, there remains the problem of how to ascertain the types for the individuals. In the model, the phenotypes are defined solely in terms of the tendency to have a certain number of progeny. In real life, the number of progeny is a normal distribution, and discrete categorization may be difficult. A further problem is why certain traits are culturally selected over others. Even if one abandons that concern to the psychologists, and simply accepts cultural selection as a given, what grounds are there for assuming that it will remain at a constant level, or not even go into reverse if other conditions change?

Because of these kinds of difficulties, the main stage for memetics research has been on the computer rather than in the wild. Software objects, or 'agents', can be programmed to behave in ways that make it possible to investigate the basic propositions of memetics. They can be given, in the jargon of object-oriented programming, attributes which are discrete values, and methods of manipulating those attributes, and the attributes of their fellows, in ways that correspond to strict rules set by the programmer. The homebodies and hellraisers of the model can be exactly reconstituted as software objects, with their parameters of reproduction and interaction precisely defined. The programmer can then easily expand the model in various ways; perhaps the external environment in which the agents exist can be partitioned into regions, each agent allowed a geographical location, and the parameters of reproduction and interaction varied in different regions. The agents might then be allowed to move, to seek out others of their own type as neighbours, or to culturally interact over long distances. One can even introduce elements of game theory into their actions, to allow them to negotiate and to deceive each other. When compared with the messy reality of human social life - difficulties of accurate categorization of individuals, uncertainty about what is cultural and what is genetic, even a lack of agreement about what culture is (eg. see Kuper 2000) - it is easy to see the appeal of artificial life as a laboratory for memeticists.

However, not everything is orderly in cyber-societies. Each small modification to the basic model adds another layer of complexity, and it is often easy to find oneself with a model that exhibits behaviour that one does not understand. Artificial societies can be just as perplexing as real ones. In the real world, we don't completely understand individuals, so we are not particularly surprised when we don't understand the societies they form. But in the artificial world, we do understand the individuals. We understand them perfectly, since we designed them. Yet, put them into social groups and inexplicable things can start to happen.

These caveats are not just peculiar to the creation of memetic models in artificial societies, but are well recognised in the larger social simulation community. They do not constitute an objection to the method in principle, but merely a warning against placing too much faith in it. So, in summary, what methodology can be used for memetics in the 21st century? I would recommend the following.

Find a problem where there is already a good body of quantitative data. It is impracticable for memeticists to contemplate collecting our own empirical data. Sociologists, anthropologists and experimental psychologists are better qualified to do the fieldwork, and we should leave it to them.

Search the literature to find out what has already been written on that problem. In particular, try to find any suggestions that processes relevant to memetics have played a part. For instance, what do social psychologists have to say on the matter? Has an evolutionary system of some kind previously been postulated?

Try to formulate an object-oriented analysis (OAA) of the problem. In particular, think about how the quantitative data relates to the agents in the OAA. How would you set up the system so that an analogous body of data could be generated?

Code a prototype of the system. Make sure you have clearly defined the social attributes of each of your agent objects and, if genetic attributes are also required, that you make a clear distinction between what is social transmission and what is genetic transmission. If there has previously been an analysis of the problem by social psychologists, try to incorporate some of the postulated social psychological mechanisms into the simulation.

Choose a starting set of parameters and run the simulation. Compare the data from your artificial society with the empirical data set in the literature. Vary the starting parameters and see how robust the outcome is to such variation.

If your artificial society has adequately reproduced what is seen in the real world, then you are justified in declaring that a set of agents with the set of attributes and methods that you have created, within the range of parameters that you have defined, is sufficient to achieve that outcome. Therefore, it could be that the mechanism in the real world is similar. If the outcomes in the artificial society are completely different to those in the real data set, then you may declare that your system is insufficient to reproduce the real world situation. In that case, the mechanism in the real world is likely to be different to that in your artificial society.

Since positive results only give indications that the real world could be as you have modeled it, whereas negative results give much stronger indications that the real world is not the same as the model, it seems that this methodology is actually quite Popperian. The function of the memeticist is to cast doubt on theories rather than to confirm them.

Is this not however, just an argument in favour of casting off the label of memeticists, and plunging into the social simulation community? Not quite; I propose that memeticists can form a recognizable sub-community by our adherence to the following requirements:

- **Always try to approach problems with a memetic or gene-meme co-evolutionary model in mind.**

- **Always work on problems which already have a good body of empirical data, preferably quantitative, against which one can falsify the theories that have been used to build the software agent models.**

What are those areas which have reasonable bodies of quantitative data? One obvious one is politics or any situation where human choices are recorded by ballots (e.g. Gatherer 2004). Another one is anthropology where there are extensive ethnographic databases (e.g. Gatherer 2002b). A third is demography where censuses of population movement are available. There are many more. The best way to find one is to ask a social scientist, geographer or historian. As well as my two published efforts in this direction (Gatherer 2002b, 2004), let me give one other preliminary example before finishing. There has been a lot of interest within the memetics community in the issue of terrorism (e.g. Marsden 2001; Lynch 2002). It was even briefly alluded to by Dawkins (1976). Memeticists often seem convinced that this is an area where the approach can make some kind of contribution. There is also a wealth of literature on the subject from other academic disciplines, including social simulation (Raczynski 2004; Eidelson & Lustick 2004), and terrorist behaviour has been variously assessed as a form of reactive warfare, organised crime, or psychopathology. There is, in at least one case, an impressive body of quantitative data: the CAIN database on the conflict in Northern Ireland from 1969-2001, available from the University of Ulster (<http://cain.ulst.ac.uk>). This database contains details on every politically motivated killing (over 3600 of them) during the 32 year period of its coverage, as well as data on the political and economic background. Figure 1 shows the number of murders attributed per year to Loyalist and Republican paramilitaries.

Figure 1: Number of killings per year attributed to Loyalist and Republican paramilitary organizations from 1969 to 2001

How do existing memetic models of terrorism stand up against such a data pattern? Is it possible to design a set of agents who would attack each other in such a way? Alternatively, is it possible to design sets of agents based on existing models who then fail to attack each other in such a way, thus casting doubt upon the model? Lynch's model (2002) only really goes as far as describing a variety of reasons, of varying degrees of cogency, why terrorism is likely to spread. One might say that Lynch is simply positing that terrorism is, in the standard terminology, culturally selected. Unfortunately, under simulation conditions, a model that simplistic merely leads to terrorism running to fixation within the population under the dynamics of a sigmoid curve (the "contagionist paradigm", see Gatherer 2002a). In effect, the agents simply kill each other off completely. The data in Figure 1 require dynamics that would explain the waxing and waning of the Republican kill rate at approximately 2-year intervals, at least during the period 1972-1989, while the opposing Loyalist kill rate was relatively unchanged year-on-year from 1979-1991. Looking not just at the overall distribution of murders, but also at their individual timing relative to each other, using a Run Test, suggests that a tit-for-tat mechanism may have been in place at some phases (data not shown). Thus a good memetic model for terrorism would not merely concentrate on trying to explain cultural selection, but would also require some game theory to be incorporated.

In summary, memetics can survive as a data-oriented branch of the social simulation field specializing in the evaluation of co-evolutionary or cultural models. Most of that evaluation will be negative, as the nature of the real world can never be confirmed using a computer model. Nevertheless, it may help us to identify cases where our a priori thinking about a cultural phenomenon is inadequate. Karl Popper would have been pleased with this.

THE INHERENT INSTABILITY OF MEMETIC SYSTEMS: USE OF A GENETIC ALGORITHM TO SOLVE A PARAMETER OPTIMIZATION PROBLEM IN A MEMETIC SIMULATION

By
Derek Gatherer
dgatherer@talk21.com

Abstract:

'Memetic isolation' is a situation in which a society or culture exhibits a cultural trait not found in any neighbouring cultures (Gatherer 2002b). A previously developed simulation, consisting of a grid of connected societies of cultural agents, is further analysed to define the circumstances under which memetic isolation is maximised and minimized. Parameters varied include migration, and cultural interaction within and between societies. Some stereotypical societies are simulated, and the differences in outcomes are analysed statistically. A genetic algorithm is then used to discover the combinations of parameters that produce extreme results. Minimization of memetic isolation appears to be simply a matter of cultural or natural selection on the meme concerned. By contrast, maximization of memetic isolation requires an intuitively unlikely combination of low cultural interaction, high migration and no selection. The classic memetic theoretical result, that horizontally transmitted memes tend to be more spatially clustered than vertically transmitted memes or genes, is shown to depend on the existence of cultural bridges, or 'weak ties', between societies and also to be at the mercy of migration rates and selective forces.

Key words: Contagion, evolutionary epidemiology of culture, cultural evolution, cultural selection, meme, allomeme, cultural trait, genetic algorithm, globalisation.

1. Introduction

A large literature exists on the relationship between genetic isolation and cultural isolation (e.g. Sokal *et al.* 1989; Barbujani & Sokal 1990; Vona *et al.* 1996; De Silvestri & Guglielmino 2000; Gonzalez Jose *et al.* 2002). Genetic isolation may be the result of a 'founder effect', where a population expands rapidly from a small set of original progenitors. This often happens in colonial situations, e.g. in South Africa (Torrington & Viljoen 1991), Venezuela (Ramirez-Duque *et al.* 1982; Vivenes De Lugo *et al.* 2003), Canada (Scriver 2001) or Finland (Kittles *et al.* 1999). It may also follow a sudden 'population crash' caused by a natural disaster or epidemic disease, followed by regeneration of the population from the survivors (Ambrose 1998; Harpending *et al.* 1998). All of these factors may also cause cultural isolation, which can then contribute to further genetic isolation if interbreeding with geographically neighbouring populations is prevented or reduced by cultural factors. However, the two phenomena are not necessarily related, and one may exist without the other.

Cultural isolation may be seen as an extreme case of 'memetic isolation' (Gatherer 2002b), defined here as the situation in which any cultural trait of a society is different to the corresponding mutually exclusive cultural trait, the 'allomeme' (Durham 1991), of any of its surrounding cultures. A true cultural isolate will be memetically isolated for an extensive selection of cultural traits.

In classic mathematical memetic theory, 'vertical transmission' refers to traits that are passed on from one generation to the next, specifically from parents to progeny (a variant is 'oblique transmission' in which traits are passed within families, but not necessarily from parent to child). By contrast 'horizontal transmission' refers to transmission within a single generation, either between siblings or other genetic relatives, or within a non-related peer group (Cavalli-Sforza & Feldman 1981). One of the results of this body of theory is that traits with more than one means of transmission have a greater tendency to homogeneity within populations, and also that horizontally transmitted traits are more likely to be spatially clustered (Cavalli-Sforza & Feldman 1973, Uyenoyama *et al.* 1979, reviewed by Cavalli-Sforza 1979). 'Spatial clustering' in this context means that individuals exhibiting the trait tend to be found in closer geographical proximity than those who do not exhibit the trait.

The present paper further investigates this area of theory using agent-based simulation. The simulation was previously described in detail in Gatherer (2002b), and may be considered as a variant of the Social Interaction Model (SIM) simulation of Axelrod (1997). Two questions are asked:

1) Under what combination of parameters is memetic isolation maximised?

2) Under what combination of parameters is memetic isolation minimised?

The answers provided enable us to refine the predictions of the original theoretical treatments of transmission and its relation to spatial clustering of traits (reviewed by Cavalli-Sforza 1979).

2. The Model

Since frequent comparison is made to the Social Interaction Model simulation of Axelrod (1997), this is described first. Imagine a set of distinct societies or cultures arrayed in geographical space. Let each culture consist of a small number of cultural traits, in the order of 10 or so.

Adjacent cultures may interact if they have a sufficient number of cultural traits in common. This situation is illustrated in Figure 1, where a minimum of four out of six cultural traits in common are required in order for the societies to interact with each other.

Axelrod SIM interaction rule

Figure 1: Rules for possibility of interaction in Axelrod's SIM. Cultural traits are represented by letters, and coloured to show which are found in common between pairs. Since the upper pair has 4 out of 6 cultural traits in common, these two societies can interact. However, the lower pair only has 2 traits in common and therefore cannot interact.

Once the two societies have established an interaction, one society may randomly adopt a cultural trait from the other. This is illustrated in Figure 2. At the end of the interaction, one of the societies has become slightly more similar to its neighbour. It is easy to see how this simple situation mirrors the process of cultural transfer in real societies. Cultures with very differing languages, religions or habits may fail to make the necessary cultural contact. However, once a certain threshold has been crossed and communication is established, cultural interaction can commence. This model makes the assumption that there is no selection for or against any cultural trait, or that traits are imposed wholesale, e.g. by conquest.

Axelrod SIM cultural adoption

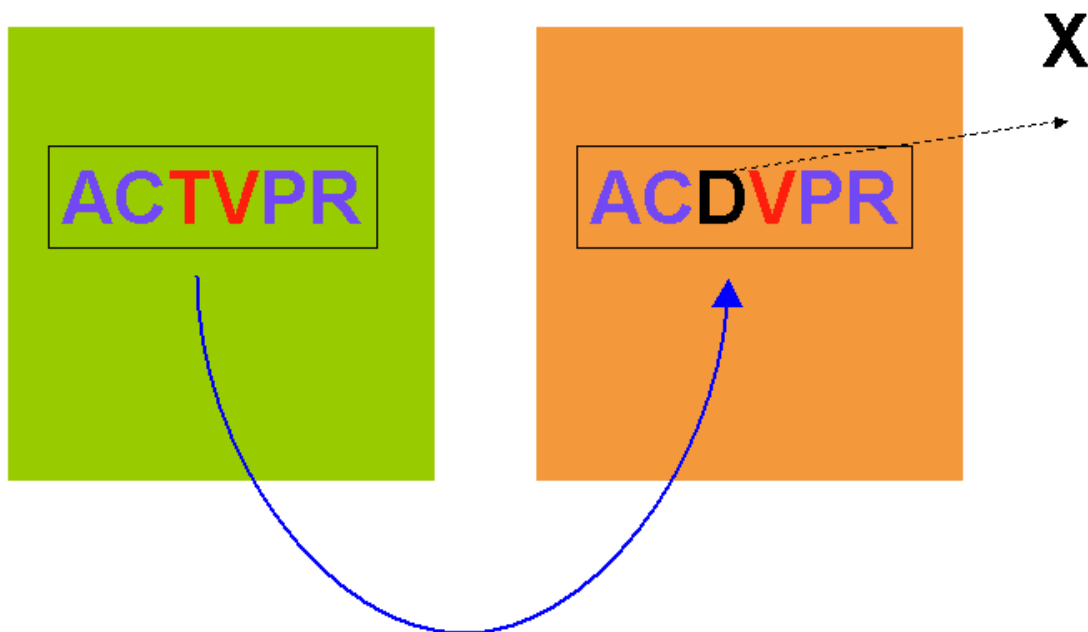

Figure 2: Adoption of one cultural trait from adjacent society in interacting SIM pair. Trait X in the right society is replaced by trait V from the left society. Having had 4 traits in common, the pair of societies now has 5 in common.

This process is repeated over several cultural generations in a grid of several cultures, typically 10 by 10, starting from a random distribution of traits. One of the principal results of SIM is that cultural 'blocs' are formed, i.e. areas on the cultural landscape with several near-identical cultures. This is especially the case if the probability of interaction is varied according to the relatedness of a pair of societies, i.e. if a pair of societies with 5 traits in common has more chance of interaction than a pair with only 3 in common, and so on. Intuitively, it can be seen that this tends to mean that societies that have previously interacted will be increasingly likely to interact further in future generations, thus producing a positive feedback.

The variation on SIM presented previously by Gatherer (2002b) uses an identical concept of a grid of societies in geographical space. The size of grid presented in the scenarios below is 10 x 10, the same order of magnitude used by Axelrod (1997). However, the focus is switched to the individual agent with the society rather than the society as a whole. SIM assumes that each society is culturally homogeneous, insofar as each society has a single set of cultural traits. Figure 3 shows how this may be adapted to allow individuals within societies to differ in their repertoire of memes and genes. The word 'genes' in this case is used as a shorthand for 'strictly vertically transmitted memes', since in haploid organisms (i.e. those with a single copy of each

gene in their genomes) these categories are formally equivalent (Cavalli-Sforza & Feldman 1981). In panel **A** of Figure 3, a grid of nine societies may be seen. Individuals are indicated as circles with their vertical memetic component as the letter **A** or **B**, and their horizontal memetic component as the colour red or blue. These individuals may perform three kinds of lifecycle activity: reproduction, migration and cultural interaction. In Figure 3A and 3C, cultural interaction is indicated with a black arrow if it occurs within societies (e.g. in the bottom right society of panel **A**, an individual with blue meme teaches it to an individual with red meme, thus resulting in that individual having blue meme in panel **B**), and a green arrow if it occurs across inter-societal boundaries. Reproduction is indicated with a white arrow and the newly produced individuals are surrounded by a dotted line in 3A and 3C. Migration is indicated by a blue arrow, and can only occur to neighbouring societies (in other words this is a 'two-dimensional stepping stone' model of migration - Rychkov & Sheremetyeva 1977). Panels 3B and 3D illustrate the end result after the processes displayed in 3A and 3C. The societies in panels **A** and **B** are coloured blue or orange according to the majority of blue or red memes respectively. In panels **C** and **D** the societies are coloured yellow or grey according to the majority of genes (or strictly vertical memes) **A** and **B**, respectively.

Figure 3: Reproduced from Gatherer (2002b). **A** and **B** labels are strictly vertical memes, red and blue colours are horizontal memes. Thus a blue individual labelled **B** has the **B** vertical meme and the blue horizontal meme. Black arrows: horizontal cultural interaction within societies. Green arrows: horizontal cultural interaction between societies. Blue arrows: migration

of individuals. White arrows: reproduction (new progeny are identical to their parents and are shown with dotted outlines). Orange squares: societies with majority red memes. Light blue squares: societies with majority blue memes. Grey squares: societies with majority of **A** vertical memes/genes. Yellow squares: societies with majority of **B** vertical memes/genes. Fuller explanation given in text.

In summary, the simulation consists of a grid of connected societies populated by cultural agents, its dynamics being defined with a set of four simple parameters:

- the rate of population growth, **r**
- the rate at which teaching/learning occurs, **o**
- the rate at which teaching/learning occurs between societies, **n**
- the rate at which individuals migrate to neighbouring societies, **m**

These parameters are designated mnemonically as **r**, **o**, **n** and **m**, respectively (i.e. reproduce, own-teach, neighbour-teach and migrate). All take values between zero and one, and represent probabilities that are either user-defined or created using a random number generator. The parameters **n** and **o** are interdependent, with **o** always evaluated first, and then **n** evaluated depending on the result of the evaluation of **o**. For example when **o** is 0.5, and **n** is 0.6, an agent will exhibit successful cultural transmission during its lifetime at probability 0.5. If that agent does exhibit cultural transmission, there is then a probability of 0.6 that that cultural transmission will be to a member of a neighbouring society, and 0.4 that it will be to a member of the same society. This could be re-expressed in terms of the notion of 'strong' and 'weak' ties, where **o** is the probability of existence of a tie, and **n** the probability that such a tie is 'weak' (sensu Granovetter 1973). A pseudocode representation of the process is as follows:

INITIALIZATION:

For each of the 100 cells in the 10-by-10 array:

```
{
    place two Agents in each cell
    randomly assign one of four Gene attributes to each individual
    randomly assign one of four Meme attributes to each individual
}
```

ITERATION:

For 100 generations do the following:

```
{
    For each Agent:
    {
        If Agent Meme attribute = "A" and CultSel = "Y"
        {
            Double parameters n and o for that agent
        }
        If Agent Meme attribute = "A" and NatSel = "Y"
```

```

    {
        Double parameter r for that agent
    }
    If a random number x < r
    {
        Reproduce Agent
    }
    If a different random number y < o
    {
        If same random number y is also < n
        {
            Transmit Meme to any Agent in any adjacent cell
        }
        else
        {
            Transmit Meme to any Agent in same cell
        }
    }
    If a different random number z < m
    {
        Migrate Agent to adjacent cell
    }
}
}

```

END.

Additionally, 'cultural selection' or 'natural selection' may be applied to one of the memes in the population. Here, these terms are used in the sense of Cavalli-Sforza & Feldman (1981), as follows: a culturally selected meme is one that has an increased probability of transmission relative to its allomemes; a naturally selected meme is one that provides a survival or reproductive advantage to those individuals that exhibit that behaviour or cultural trait.

Figure 4 provides a diagrammatic representation of the agent in UML (Universal Modelling Language). The simplicity of this agent (all attributes and methods public, no constructors etc) is due to its implementation as a Perl record rather than a true object in Java or C++. Perl records are fairly analogous to struct in C. Agents have one of four Meme attributes ("A", "B", "C", "D") and one of four Gene attributes ("1", "2", "3", "4").

Figure 4: UML diagram for the Agent class. Attributes are above the line and Methods below. Public scope is represented by a "+" (all are public)

Perl scripts are provided in the Appendix that:

- run the simulation with graphical output
- implement a genetic algorithm (GA) to optimise the parameters.

Both scripts require Perl, and the first also requires the Tk graphics library. A recent version of ActivePerl (Build 6 series or more recent, freely available from <http://www.activestate.com>) provides all the necessary library components. All scripts provided have been tested on RedHat Linux 6 running Gnome, and on Microsoft Windows 98.

3. The Effects of Varying Parameters on Memetic Isolation

The 'memetic state' of a society for a certain cultural trait, is here defined by the 'first-past-the-post' voting method. The Meme attributes of each agent in the society are scored, and if allomeme "A" scores more than any of the other three Meme attributes, the memetic state of that society is "A". If allomeme "A" is not the highest scoring attribute, the memetic state of that society is "not-A". 'Memetic isolation' occurs when that society's 'memetic state' is "A" and that of all its immediate neighbours is "not-A". The overall memetic isolation is the percentage of societies that are in this state. It is admitted that 'first-past-the-post' is potentially a flawed means of scoring a society, but it is often used in sociological contexts. For instance, statements such as the "Belgium is a Catholic country" are simply expressions of such head counts. Qualifying those situations where the 'first-past-the-post' voting produced a narrow majority, perhaps by the use of a 'marginal' label, could further refine the model. However, this would be complex enough to merit another paper, and so is not dealt with here.

'Genetic isolation' can similarly be calculated using the Gene attribute "1". Since the agents are haploid (i.e. they have only a single Gene attribute), the Gene is equivalent in terms of its transmission to a strictly vertically transmitted meme, as demonstrated by Cavalli-Sforza & Feldman (1973). It is thus possible to contrast 'memetic isolation' and 'genetic isolation' in terms

of the likelihood of isolation for horizontal and vertical memes. Therefore, 'genetic isolation' is used hereafter simply as a shorthand for 'memetic isolation for strictly vertical traits'.

3.1 Scenario 1: The Random Background - the "strictly vertical model"

The scenario is initialised with two individuals per cell, and allowed to run for 100 generations with a rate of population growth (r) of 0.01 per generation. Migration (m), and the two social interaction variables (o and n) are set at zero. This simulates a situation where societies grow slowly in size, but there is no 'horizontal transmission' (Cavalli-Sforza & Feldman 1981), or movement of individuals across society boundaries. It is essentially a non-cultural population, or perhaps more exactly a population where culture is contained strictly within vertical lineages. This is given merely to demonstrate the properties of the system in a background state, where as little as possible is happening except the effects of randomness over a large number of cycles. It is difficult to think of a real-world example of this kind of cultural situation; even non-human species with aspects of culture, such as song birds and great apes, do not limit cultural transmission within genetic lineages (e.g. Burnell 1998; Lynch et al. 1989; Reader & Laland 2000; van Schaik et al. 2003). The scenario was repeated 100 times and the average memetic and genetic isolation measured. These were found to be 3.23% and 3.00% respectively. Statistical significance was assessed using a paired t-test. In this and all subsequent scenarios, t-tests are two-tailed, as there is no a priori expectation that parameters will increase or decrease levels of isolation. A paired t-test between the genetic and memetic isolation values for each of the 100 runs, was not significant, thus indicating that both horizontal and vertical memes behave identically in strictly vertical populations. In effect, the 'horizontal memes' are forced to become vertical memes by the absence of cultural interaction in the population, and thus this scenario constitutes a sort of *reductio ad absurdum*. However, it is necessary to demonstrate the basic background behaviour against which other scenarios will be measured.

3.2 Scenario 2: Introducing Cultural Exchange within Societies - the "desert island model".

Social interaction within societies is now permitted, by raising parameter o to 0.5. This means that each agent will transmit a horizontal meme with probability 0.5 within its lifetime, in other words half of all agents transmit horizontally per generation, and half do not. All other parameters are the same. This recreates the situation of societies between which there is no contact, but which have a flourishing social life of their own, such as might occur on extremely isolated oceanic islands. It should be noted at this point, and for all subsequent scenarios, that it is recognised that real societies are infinitely more complex than any simulation can reproduce. The purpose of adding labels such as 'desert island' to the simulations, is really to serve as a mnemonic shorthand, and also to perhaps act as an 'intuition pump' for practical applications. After 100 generations, over 100 runs of the scenario, the average genetic and memetic isolation values are 3.16% and 4.08% respectively. A paired t-test shows these to be statistically significantly different at $p < 0.0004$. Thus, against a background of no migration and no cultural exchange between societies, social interaction within our artificial societies increases the likelihood that those societies will be memetic isolates. This is because the rate of the random walk amongst competing allomemes in those societies is speeded (see Gatherer 2002a, Fig. 2). If o is raised to 1, allowing each agent a successful cultural transmission event per lifetime, the figures are essentially unchanged. This is called a 'desert island' model, since it would apply only

to societies that were completely cut off from the rest of the outside world. Some examples are known, of which the best studied is perhaps that of the Bounty mutineers on Pitcairn Island, who remained completely undiscovered for decades after settling, and in effective cultural isolation for some years after. In this period they were able to evolve a unique culture incorporating both European and Polynesian elements, including a new creole English language (Refsauge & Walsh 1981). If one imagines a thought experiment in which the Bounty mutineers colonised two separate islands, mutually unconnected, the model predicts that they would become memetic isolates for many traits. This rarely applies to many island archipelagos, as the inhabitants are often in contact, albeit infrequently. This leads to the next scenario where such an arrangement is permitted.

3.3 Scenario 3: Introducing Limited Cultural Exchange between Societies - the "Paleolithic model"

Parameter n is now raised from zero to 0.01. This permits cultural exchange with a neighbouring society at a probability of $0.01 \times o$ per individual per generation. Therefore at o of 0.5, the rate of inter-cultural exchange is 0.005. The societies are now no longer totally isolated "desert islands", but have the kind of casual contact perhaps normal for sparsely distributed and occasionally trading nomadic bands. Over 100 runs of the scenario, again for the standard 100 generations, average genetic isolation remains around the background level at 3.12%, but memetic isolation drops to 1.78%. A paired t-test shows this to be a significantly different value for memetic isolation at levels of p tending to zero. Thus even a small amount of cultural exchange between our artificial societies may, *ceteris paribus*, create tendencies to cultural homogenisation on a local geographical scale. Cultural blocs (Axelrod 1997) thus begin to emerge out of a patchwork background. Where parameter n is increased, memetic isolation falls even further: at $n = 0.1$, memetic isolation falls to 0.71%. Thus in a scenario of 100 societies, most runs terminate without a single memetic isolate at the end of 100 generations. This is called the 'Paleolithic model' as it very roughly recreates a situation hypothesised to have existed in Late Ice Age Europe, where nomadic bands of hunters of large herds of bison, mammoths etc, would have existed in isolation punctuated by brief seasonal periods of contact at assembly points, perhaps associated with exchange of gifts, arrangement of marriages and ritual behaviour (e.g. Rudgley 2000). A more modern example may be provided by the Andamanese, who remained in relative isolation within their archipelago for many thousands of years (e.g. Thangaraj et al. 2003). Again it bears reemphasis that the correspondence between the artificial societies and the anthropological examples given is quite naïve, and really just raises the issue of how better models of such societies could be created, rather than claiming to have created one here.

3.4 Scenario 4: Introducing Natural Selection - the "Neolithic model"

Meme "A" is now submitted to natural selection. This means that those agents with Meme attribute "A" have twice the normal chance of reproduction of those with the other three allomemes. Meme "A" agents thus reproduce above replacement at a probability of 0.02 per generation, instead of the 0.01 for the other three allomemes. This is termed here the "Neolithic Model" as it is reminiscent of one of the main theories for the Neolithic transition in Europe, namely that the cultural activity of farming provided a reproductive and survival advantage, in that early farmers were able to feed more children and live longer to reproduce more, compared

to their Mesolithic hunter-gatherer neighbours (Renfrew 1987). If **m**, **n** and **o** are all set to zero, so that there is no migration or cultural exchange within the population, but natural selection is permitted to increase **r** from 0.01 to 0.02 for Meme "A" individuals, genetic isolation after 100 generations is 3.68% and 2.34%. This memetic isolation is significantly different to the background "pre-cultural model" (See 3.1), although both models have no cultural exchange. The reason for this is that the evolutionary advantage of Meme "A" in terms of natural selection means that this meme will tend to take over the populations in which it is found. If it happens to occur in two adjacent societies, even at initial low frequencies, it will eventually run to fixation in those societies. Of course, this is not really a good "Neolithic model", as Neolithic societies also had cultural exchange as well as natural selection for a meme (assuming for the present that this particular theory of Neolithic transition by demic expansion is true). A second "Neolithic model", allowing levels of cultural exchange equivalent to the "Paleolithic model", i.e. **o** = 0.5 and **n** = 0.01, has levels of genetic and memetic isolation of 3.37% and 1.11%, respectively. A t-test shows that this is a significantly different level to that when there is no natural selection. Natural selection of a meme thus reduces its likelihood of memetic isolation.

3.5 Scenario 5: Introducing Cultural Selection - the "Contagion model"

The second "Neolithic model" above, now has natural selection of Meme "A" replaced by cultural selection. This means that Meme "A" will be transmitted at double the normal frequency of cultural exchange. Thus with **o** = 0.5 and **n** = 0.01, as above, Meme "A" has probabilities of transmission of **oA** = 1 and **nA** = 0.02. Genetic and memetic isolation after 100 generations average to 3.24% and 0.21%, respectively. Therefore, cultural selection almost removes memetic isolation entirely.

3.6 Summary of scenarios

Table 1 show the summary of the scenarios

Scenario number, number of section where described and name of model	m	n	o	select.	Genetic isolation (%)	Memetic isolation (%)
1: 3.1 Strictly vertical	0	0	0	None	3.23	3.00
2: 3.2 Desert island	0	0	0.5	None	3.16	4.08
2: 3.2 Desert island - 2	0	0	1	None	3.26	4.04
3: 3.3 "Paleolithic"	0	0.01	1	None	3.12	1.78
3: 3.3 "Paleolithic" - 2	0	0.1	1	None	3.33	0.71
4: 3.4 "Neolithic"	0	0	0	Natural	3.68	2.34

4: 3.4 "Neolithic" - 2	0	0.01	0.5	Natural	3.37	1.11
5: 3.5 Contagion	0	0.01	0.5	Cultural	3.24	0.21

Table 1: Summary of the average genetic and memetic isolations resulting from the various scenarios. The 'strictly vertical' model provides the random background level of isolation. The 'desert island model' shows the highest level of memetic isolation. **m**: migration, **n**: cultural interaction within societies, **o**: cultural interaction between societies

Several questions may now be answered by using t-tests to compare the statistical significance of differences between rows in Table 1. In this section, t-tests are two-tailed and non-paired, since comparison is between different scenarios. An F-test is first carried out to establish if the t-test should be heteroscedastic or homoscedastic.

What factors affect genetic isolation?: Method: t-tests between genetic isolation data for all rows against row 3.1 (where there is the random background level of genetic isolation). Answer: no model significantly changes the likely degree of genetic isolation of each society. The differences within the range of 3.12% to 3.68% are all explicable as statistical random variation. This applies equally to cultural traits that are strictly vertically transmitted.

What factors affect memetic isolation?: Method: t-tests between memetic isolation data for all rows against row 3.1 (where there is the random background level of memetic isolation). Answer: by contrast with the above, all models have a level of memetic isolation significantly different to the random background at $p < 0.01$. The answer is therefore completely different to the above, in that one might say that several factors may influence memetic isolation, including cultural and natural selection, and the rates of cultural transmission.

Does the "Neolithic - 2" have less memetic isolation than the basic "Neolithic" model? Method: t-tests between memetic isolation data for rows "3.4 Neolithic" and "3.4 Neolithic - 2". Answer: yes, at p tending to zero. Therefore, it is possible to conclude that an increase in social interaction within a society decreases memetic isolation when the meme is under natural selection, whereas it increases it when natural selection is not operating (compare "Strictly vertical" and "Desert Island").

Does "Contagion" have less memetic isolation than any of the other models? Method: t-tests between memetic isolation data for all rows against row 3.5. Answer: yes, "Contagion" has a significantly lower level of memetic isolation than all other models at p tending to zero. It is thus possible to say that culturally selected traits are unlikely to exist in isolation.

4. The Genetic Algorithm

The above set of simulations only dealt with seven scenarios as compared to a random background. However, since there is a combinatorial explosion of possible scenarios, a heuristic method must be used to select the scenario most likely to give rise to extreme conditions.

A standard method for use in such situations is the Genetic Algorithm (GA - reviewed by Bentley 1999). The general form of the GA used here is as follows:

```
START: Randomise representations of the parameters in a linear string.  
FOR n CYCLES  
{  
    Assess the result of those parameters by 100-generation simulation  
    Rank strings by the result under investigation (e.g. maximal memetic isolation)  
    Discard very worst performers  
    Recombine and/or mutate remainder of unacceptable performers  
    Retain and reproduce acceptable performers to maintain constant numbers of strings  
}  
END.
```

In the GA presented here, the threshold below which GA strings are discarded is 0.775 standard deviations below or above the average memetic isolation, depending on whether the GA is attempting to maximise or minimise memetic isolation. The threshold for mutation and/or recombination is 0.5 standard deviations above/below the average. Mutation and recombination occur with probabilities of 0.05 and 0.1 respectively, but only within the sub-standard group. The better performing strings are thus protected from mutation and recombination (this is quite a Lamarckian GA!). These properties were derived by a process of empirical trial and error, and there are many other forms of GA that could be used. The balance between homogenisation, due to selection, and diversity, due to mutation and recombination, is a delicate one, and has to be solved afresh for every situation in which a GA is used. It should be noted that the fitness landscape is extremely noisy. In all the scenarios above in section 3, the standard deviation of the memetic isolation is high. For this reason, it appears to be more profitable to protect the better performing strings. The GA process is illustrated in diagrammatic form in Figure 5, and the continuing high standard deviation may be seen in Figure 6.

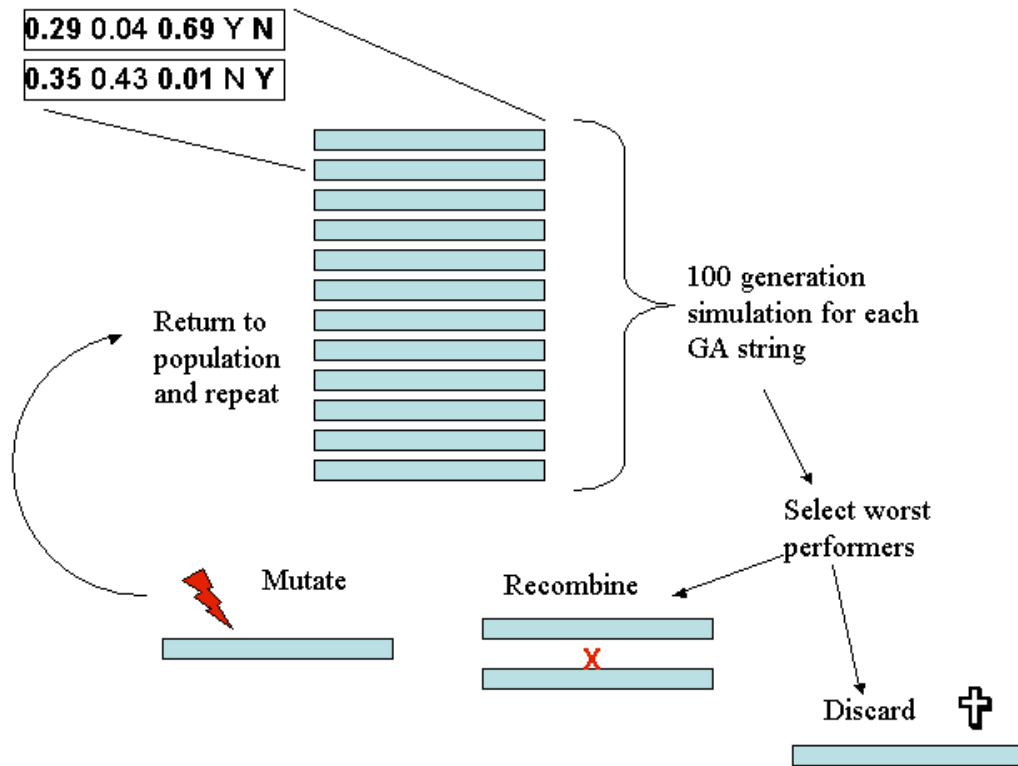

Figure 5: Diagrammatic representation of the GA process. The starting sets of parameters for the model are represented as a string of length 5. Each string is run as a separate simulation, and the results are assessed according to the desired outcome (e.g. high memetic isolation or low memetic isolation). The 'worst' performers according to the desired criteria are either discarded, mutated or recombined with a randomly chosen other member of the population. The discarded strings are replaced by randomly chosen strings from the better performing part of the population. Selection of GA strings thus tends to homogenise the population while mutation and recombination maintain some variability. The whole process was repeated over 100 cycles.

A set of GA strings was prepared by semi-randomly initialising the variables, **m**, **n** and **o**, and the selective conditions for cultural and natural selection, 50 times. The initialisation is semi-random as the starting set was biased to give fairly low levels of migration. The initial set produced is shown in abbreviated form in Table 2. After 100 iterations of a GA process, selecting for maximum memetic isolation at each stage, the 50 populations corresponding to the 50 GA strings have average memetic isolation of 4.60% and average genetic isolation of 4.72%. The set after 100 GA generations is shown in abbreviated form in Table 3. The most obvious feature of the action of the GA over 100 generations of searching for best parameters for maximum memetic isolation is to eliminate cultural and natural selection. The GA also optimises memetic isolation by reducing the rate of cultural exchange within the culture, variable **o**, from the initial average of 0.462 to less than 0.005. Migration is increased from 0.048 at initialisation to 0.559. The optimal value for teaching to other societies is also maintained fairly high, at 0.432 from

0.501 at initialisation, but this will still represent a small level of cultural exchange since the background probability of cultural exchange is less than 0.005.

Growth rate	Teach own society	Teach other society	Migration	Cultural Selection	Natural Selection
1 0.01	0.24	0.89	0.04	Y	N
2 0.01	0.41	0.46	0.07	Y	Y
3 0.01	0.44	0.58	0.05	N	Y
Several rows.....					
49 0.01	0.12	0.06	0.01	N	N
50 0.01	0.14	0.90	0.07	Y	N
Average	0.462	0.501	0.048	21 Y	18 Y

Table 2: Truncated listing of 50 GA strings semi-randomly initialised at 5 parameters

Growth rate	Teach own society	Teach other society	Migration	Cultural Selection	Natural Selection
1 0.01	0	0.81	0.5	N	N
2 0.01	0.01	0.81	0.5	N	N
3 0.01	0	0.81	0.5	N	N
Several rows.....					
49 0.01	0	0.81	0.5	N	N
50 0.01	0	0.81	0.5	N	N
Average	0.0048	0.432	0.5592	0 Y	0 Y

Table 3: Truncated listing of 50 GA strings after 100 generations of the GA process, selecting for maximum memetic isolation

When the same process is performed, but the selective conditions are to minimise memetic isolation, the resulting average parameters are compared in Figure 4. The minimisation GA was

only performed over 7 rounds of selection, as compared to 100 rounds for maximization, as it rapidly achieves a near-zero rate of memetic isolation.

GA seln. (rounds)	Teach own soc.	Teach others	Mig.	Cult. Seln.	Nat. Seln.	Mem. Isol.	Gen. Isol.
Minimise (7)	0.49	0.60	0.49	23/25 Y	23/25 Y	0.02%	3.43%
Maximise (100)	0.0048	0.432	0.5592	0/25 Y	0/25 Y	4.60%	4.72%

Table 4: Comparison of 25 rounds of GA selection for the optimal parameters to maximise memetic isolation, with 7 rounds of selection for the optimal parameters to minimise memetic isolation.

The progress of the memetic isolation-maximising GA is shown in Figure 6.

Figure 6: Progress of the genetic algorithm in selecting parameters to maximise memetic isolation. Red: the average memetic isolation in the 50 populations corresponding to the 50 GA strings. Blue: the standard deviation of that average throughout the 50 populations. The persistence of a relatively high standard deviation illustrates the 'noisiness' of the system.

5. Discussion

The contemporary phenomenon of globalisation involves cultural as well as economic aspects. It has been estimated that 5.6% of the world's languages are in danger of extinction, and a further 4.4% have recently become extinct (Sutherland 2003). In the Social Interaction Model (Axelrod 1997), this phenomenon was seen as an emergent property. SIM is another grid-based agent model in which neighbouring agents are permitted to exchange information with other societies providing they shared at least one cultural trait. SIM has a single agent per grid square, which can either be taken as an individual or as a whole, and necessarily homogeneous, society (Axelrod suggests 'homogeneous villages'). There is no migration. SIM leads to the increasing homogenisation of agents in close proximity, while at the same time agents that had by chance no common traits with their neighbours, remain completely differentiated. If the SIM agents are treated as individuals, SIM demonstrates how neighbouring individuals can form homogeneous cultural areas. Similarly, if the SIM agents are regarded as homogeneous societies, SIM demonstrates the formation of cultural 'blocs' on a local geographical basis. The model presented here differs from SIM, in that it is necessarily based on individuals. Societies are simply geographical areas, whose cultural profiles depend on those of the agents that inhabit them.

Another important difference is that in the present model, the level of social interaction between societies is constant for each run of the scenario, and is defined by parameter **n**. However, in SIM, the analogous parameter is proportional to the number of cultural traits that neighbouring agents have in common. Thus, if there are no traits in common, neighbouring agents will not interact, thus creating a local 'desert island' model. If the SIM agents are seen as homogeneous societies, SIM thus simultaneously operates a 'desert island' model and a 'Palaeolithic model' within the same scenario, with the two models operating in different parts of the grid, with shifting boundaries as the scenario progresses. A model more similar to the present one in its structure, is given by Ray et al. (2003), but those authors focus exclusively on the genetic phenomena and do not deal with horizontally transmitted cultural entities.

The genetic algorithm process presented here seeks to derive parameters for the prevention of cultural blocs. It delivers maximal memetic isolation (an average of 4.6% of societies are memetic isolates after 100 generations of the scenario) at levels of social interaction tending to zero (less than 0.5% per person per lifetime), and with high migration (over 55% per person per lifetime), where no selective conditions operate. This describes a rather nightmarish scenario where there is little or no social communication between continually wandering individuals. There is some superficial similarity here to theories of 'alienation' (Geyer 1994). Although technically, this might be the optimal way of maintaining memetic diversity in a grid of artificial societies, it is clearly not a solution that any would prescribe in the real world. It is also completely vulnerable to selection pressures where they arise. Even in situations of very low social interaction, a culturally selected meme will tend to spread through a population (see Gatherer 2002a, Fig. 4). When there is no social interaction at all, and cultural selection ceases to operate, natural selection can still push memes to fixation through growth of the lineages that exhibit them. In effect, extreme migration rates cause the cellular nature of the scenario to break down, and effectively become a single society. Parameters **o** and **n** then cease to have any significance, as cultural transfer occurs principally by transfer of people.

How would one make the model more comparable to the real world? Empirical studies of Australian Aborigines suggest a realistic figure of 0.12 to 0.13 for m , where the pattern of migration is mostly to neighbouring tribal groups and rarely to more distant tribes, reflected in the present model (Lasker & Crews 1996). Migration rates of $m \sim 0.55$ are rare in the real world. Where they do occur they are often in specific directions, e.g. invasions, flight of refugees, economic migration, and are not reproducible in the present model. Even when they do, they are often smaller than $m \sim 0.55$. For instance even at the height of the potato famine in Ireland, the total decline in population over the decade 1841-1851 was about 20%, including migration and death (although of course a decade does not constitute a lifetime, so the figures are not strictly comparable). The largest migration occurring in a single year, the 17 million people that migrated from one part of the Indian subcontinent to another after partition, still only accounted for some 7% of the Indian population at the time. Modern radiochemistry is beginning to show that Neolithic populations may have been more mobile than previously thought (e.g. Montgomery et al. 2000). There are some interesting questions that could be addressed in this area using scenarios of the sort presented here, once accurate parameters can be estimated from the empirical data, such as why late Neolithic Malta became a cultural isolate after two millennia in contact with the rest of the Mediterranean (e.g. Robb 2001; Schulting & Richards 2002). Empirical studies to determine realistic values of parameter θ may be more problematic, but there may be some clues from anthropological field studies of cultural transmission (e.g. Hewlett & Cavalli-Sforza 1986).

When set to minimise memetic isolation, the GA simply identifies cultural selection as the overriding factor in this. As modelled here, contagious memes run to fixation within societies, and when transferred to neighbouring societies, do the same there. However, it is also clear that this is a naïve representation of the likely course of contagion within a society. Gatherer (2002a) shows that there are several factors that can derail 'the contagionist paradigm', and that random, or pseudo-random, walks are more likely than sigmoid curves when considering meme frequencies within any society.

The effect of modern mass communication media is to amplify the horizontal mode of transmission so that one individual can communicate with many more individuals simultaneously than would be possible in a lifetime of individual contacts (Cavalli-Sforza & Feldman 1981). This situation is not explicitly modelled either here, or in SIM, but could easily be incorporated. Axelrod (1997) suggests a model where long-range interactions are permitted and probabilities of interaction are based on such long-range communication networks, rather than geography. Gould & Tornqvist (1971) describe a transition from a spatially contagious pattern of cultural spread to a hierarchical one dominated by rapid transfers between urban centres. These authors cite Pyle's (1969) work on cholera by way of example: the 1832 epidemic in Montreal and New York spread slowly down the Ohio/Great Lakes river system. In 1865 by contrast, several major cities, by that time connected by rail, were struck simultaneously, and the second wave of the epidemic struck towns connected to those major cities. Thus, for societies in the industrial phase of development, it is clear that such a spatial grid model (whether using SIM or the model presented here) is inadequate.

However, although the initial model was conceived as a representation of a geographical grid of societies, in order to compare the results of simulations with a geographically ordered

ethnographic data set (Gatherer 2002b), it is also possible to consider it more abstractly, as a single large society partitioned into smaller social networks. This effect is in any case forced on the scenario at high values of **m**, such as that produced by the GA. The arrangement of the cells on the grid does not then refer to any geographical separation of sub-societies, but to their separation in terms of the likelihood of weak ties. Sub-societies that are not adjacent on the grid will have no weak ties at all between them, and those that are adjacent will have weak ties with probability **n** per individual per generation.

In summary, it has been known for over a quarter of a century that memes have a greater tendency to homogeneity within populations than genes, and also that memes are more likely to be spatially clustered (reviewed by Cavalli-Sforza 1979). In the context of the present scenario, 'spatial clustering' can be taken to mean an absence of memetic isolation, or in Axelrod's terms the formation of 'cultural blocs'. The scenarios presented here demonstrate that, where societies are totally isolated (the "desert island" model, section 3.2) the tendency to memetic isolation is actually increased. However, where cultural exchange, even at a tiny level, is permitted between neighbouring societies, memetic isolation declines precipitately (the "Paleolithic" model, section 3.3). Where the meme is also under selection, especially cultural selection, memetic isolation falls towards zero (the "Neolithic" and "Contagion" models, sections 3.4 and 3.5).

Therefore the inherent tendency of memes to be more spatially clustered than genes depends on the existence of cultural bridges, or 'weak ties' (Granovetter 1973), between societies. The GA results confirms the primacy of selective pressures in creating spatial homogeneity, but also suggests that such homogeneity can be rapidly fractured by high migration rates. Memetic systems can be seen to be highly unstable, especially when the selective forces at work within them are also cultural. Culture is always close to chaos.

Appendix: Code Listings

All listings require Perl to be installed, and should run under both windows and Unix. In the event of any problems, please contact the author.

Abstract

An impressive body of discourse analysis of organizational communication has added credence to the view that organization emerges in communication, but, as Nardi (1996) observes, the problem of explaining organizational persistence remains unresolved. In this paper the authors propose a model of organizational persistence as a memetic phenomenon. We argue that structures of meaning that describe action are composed of a limited set of bases (the equivalent of nucleotides): agents, events, objects, recipients, intentions, etc. These bases are then strung together to produce structured units describing narratively-based archetypes of action by means of which organization is both generated and understood. However, unlike DNA, such structures are single-stranded. We hypothesize that for them to replicate, the participation of other agents capable of playing a complementary role is necessary. We define such interaction as *conversation*. The equivalent of mRNA is thus the speaker of language, by means of which the patterns inscribed in the 'memome' of the speaker are 'read off' and produced as speech or written text. In linguistics this corresponds to the transposition of semantics into syntactics. Conversation is thus the process of conversion of narrative into action, mediated by language, and constrained by the forms of conversation (as studied in Conversation Analysis). Similarly, textualization is defined as the process of conversion of action into archetypal narrative or "making sense" (Taylor et al, 1996). The function of interaction is to give structure to the context of action in which communication is embedded (including material objects that enter into action). The social equivalent of the cell is thus the organization which is composed of the set of self-reproducing systems. Communication thus both organizes context, and explains it. It is the sum of material, symbolic and social elements that compose the 'molecular soup' of the work environment that makes up organization, and not just communication. Nevertheless, communication is the carrier of structure, and explains organizational persistence.

Introduction

An impressive body of discourse analysis of organizational communication has added credence to the view that organization emerges in communication (Taylor & Van Every, in press), but, as Nardi (1996) observes, the problem of explaining organizational persistence remains unresolved. In our attack on the problem, we take the structuration theory of Giddens (1976, 1979, 1984) as our starting point.

Structuration as an explanation of organizational persistence

Giddens breaks with the established dualistic tradition of Western thought - the life forms of society and of the individual conceived as ontologically distinct levels of reality - by proposing a theory of *duality*, where both social and individual existences are co-constructed in the ordinary sphere of daily interaction. To accomplish this shift of perspective, he proposes to focus on the stream of activity which constitutes, without exception, the immediate experience of humanity (a version, perhaps, of Heidegger's concept of 'thrownness'). That which must then be explained, sociologically, is the "continuity of practice" transcending the strictly local and time/space situated (what we described above as "persistence") which clearly characterizes social forms of organization whose continuities extend over time, and across space. His central hypothesis is that this is achieved through reflexivity, i.e., "the monitored character of the ongoing flow of social life" (Giddens, 1984: 3). Human action occurs as an uninterrupted flow (that he calls a '*durée*'). It is experienced, however, as a structure of actions and reactions, each informed by human purpose. That which makes the continuous flow of conduct and cognition appear to be structured is what he calls "rationalization" (Giddens, 1984: 3). Such rationalization is "a routine characteristic of human conduct, carried on in a taken-for-granted fashion" (Giddens, 1984: 4) to produce the "encounters and episodes" that allow us to interpret life as motivated by intention and socially meaningful. That which explains persistence of organizational structure must thus be found within the rationalization process, as a central characteristic of it.

It seems evident to us (although this is not Giddens' primary emphasis) that the rationalization of which he writes is accomplished as an effect of the mediation of language in a context of communication. If the monitoring of activity and its rationalization to generate a motivated universe of action is achieved by its representation in forms of language, as cognition or conversation, then it is the monitoring-->rationalization process, as an effect of languaging, which explains persistence: That which persists is not the transient instantaneity of the flow but its *interpretation* or symbolic representation. Since rationalized experience becomes in turn how the situations that frame subsequent activity are experienced (Weick's 1979 concept of *enactment*) it is in this way that people are enabled to discriminate the structural continuities that enable social life, as they migrate from one time/space configuration to another. It is this that makes social (as well as cellular) life not just organized, but self-organizing (Taylor, 1995). Our hypothesis is that the rationalization process can be explained as a memetic phenomenon. There is in other words a homomorphism linking social organizational and organismic cellular processes of self-organization. We take this to be not an exact model, but a loose analogy, and it is this analogy we are exploring.

The genetic analogy

The central unit of biological self-organization is the cell. The cell survives as an entity because it is self-regenerating (autopoietic). We propose that, by analogy, human social organization is similarly self-regenerating, and that the role played by gene structures in biological reproduction has a memetic analog in organizational persistence, although the analogy is far from one-to-one, in that while language presumably has structuring properties analogous to those of DNA its role is not identical, and the process by which its patterns are reproduced manifest significant differences from those studied by geneticists. The purpose of this paper is to outline, in a very preliminary way, some of the commonalities and divergences.

In exploiting the genetic model of cellular reproduction we inherit three concepts: replication, transcription and translation. In cellular reproduction, replication is accomplished by the splitting of the double strand of the gene to produce two identical copies. Transcription of the information encoded in the DNA requires the agency of mRNA which "reads" off the genetically encoded information and transfers it to the "manufacturing plant" of the cell where, assisted by enzymes, it is then "translated" into proteins. The proteins then become the active agents in sustaining the ongoing process. Each of these three stages, we propose, are also characteristic of the memetic cycle, even though the modes of accomplishment are by no means identical. We consider each of the phases in turn, beginning with transcription.

Memetic transcription

There is, as is well known, a genetic syntax: Strings of DNA are composed of one of four bases (nucleotides), grouped into triplets (codons), organized into larger structures (genes), then into chromosomes and eventually a genome. But there is also a semantics of genes: Genotypes map (in complex ways) characteristics of the phenotype. The organism is constructed out of materials whose patterns are genetically encoded: A gene can for example be conceptualized as the recipe for a specific protein. In a general way, this correspondence also characterizes the role of language with respect to social organization. Language is also distinguished by a hierarchy of levels, from phonemic to grammatical to narratively informed units to text. At the level of strings of elementary symbols (beginning with the sentence) language encodes social structures: "I just bought myself a new winter coat" is not just a statement in language, it is an encoded organizational event that supposes the existence of buyers and sellers, markets and stores, and institutional arrangements that govern them. Language, at the level of semantics, distinguishes actors, agents, events, actions, instruments, objects, exchange dynamics, process, place and circumstance. And it does so in a way that constructs time as a structured unfolding: a pattern of interconnected events. It contains, in other words, all those elements that allow organization to be constructed, cognitively, as a lived reality - "rationalized." Such semantic patterns, we further propose, correspond to a semionarrative patterning of meaning: mirrored in the single utterances and sentences of speech, but realized in suprasentential configurations having their basis in story syntactics (Taylor, 1998; Cooren & Taylor, in press; Groleau & Cooren, in press; Robichaud, in press).

There is not space in this brief paper to develop this idea in full. Instead, we state as a working hypothesis that the semantics of language have precisely those properties of representation that

make Giddens' theory of reflexive monitoring and rationalization feasible. Experience, once textualized, is made meaningful. The "meme" is (and here the parallel with the gene is evident) that component of language which is capable of mapping a single feature of organization. Our hypothesis is that when it is read off, in a context of conversational exchange, it also provides the template for the *building* of the elements of organization, as a discursively realized phenomenon. This transcription is what we term 'actualization' (Robichaud, 1998). For such a hypothesis to be tenable, we would have to suppose that, in spite of the great variety of human spoken languages, the underlying semantic properties of all are the same. There is, fortunately, encouraging evidence to support this view that the semantics of language are characterized by patterns that are found universally in all the diverse tongues spoken by humankind (Bickerton, 1990).

It follows that the memetic equivalent of mRNA is speech. We assume that people, in speaking, draw on a repertoire of symbolic material - words, phrases, imagery, sayings, stories, analogies, lines of argument, etc. - that reflects stable properties of the speaker's semantic representation of the organizational world which formed him or her: He or she is transcribing memetically encoded patterns in the process of speaking. Again, given the constraints of this paper, we are obliged to enunciate this as a working hypothesis, without further defense.

Memetic translation

Proteins are constructed by adjoining amino acids to form the complex patterns which distinguish one protein from another. We hypothesize that the "proteins" of social organization are patterned sequences of consecutive, inter-related acts, equivalent to what Schank and Abelson (1977) described as "scripts." These authors draw, as a concrete example, on what they call a "restaurant script" to show that the actions of both restaurateurs and clients fit together interactively to construct an event or episode, not because the spoken interventions of those involved are self-containedly meaningful, but because the indexical expressions used by participants ("Table for two, sir?", "Smoking, non-smoking?", "Bill?") is a recognizable transcription of components of the script. That which is being produced is not just speech, but a meaningful interaction that contributes to the persistence of a social institution, eating at a restaurant. The role of language is double: to encode the pattern of the event (in what we call its "text") and to mobilize the practical elements going into a meal - food, kitchen, building, check-out counter, etc. - by supplying the necessary procedural guidance by means of which the material substructure of dining is effectively organized. In speaking the actors are actually *acting out* the organizational structure (Giddens' point). By analogy, this is how all organizations are constructed.

There is, however, an obvious difference in the transcription processes of the cell and the human organization. In the cell, there is a direct transfer of the information encoded on one of the strands of the double helix, via the agency of mRNA, in the aligning of amino acids to form a given protein. In the organizational conversation, the production of a unit of organization necessarily supposes a mutuality of patterning: The restaurant customer and the waiter, for example, have complementary roles to play. The "double helix" of organization is thus constituted, not as a permanent binding of complementary strands, but as an occasioned event where the "code" of the organization will have been successfully realized if the occasioned 'eventing' is regularly accomplished.

Memetic replication

The replication of the memetic pattern is thus intrinsically dependent on the dynamic of interaction. The persistence of cultural patterns, historically and geographically, gives empirical support to the idea that, in general, replication occurs, organizationally as well as biologically, with relatively constant fidelity. But it should be obvious that the process is contingent on situational variables, almost certainly to a greater degree than is the case for genetic replication. There is no reason to think, though, that the *principle* of replication is any less applicable to organizational as to organismic reproduction. All that is required is that the participants in the exchange find their model confirmed by their experience: The satisfied diner leaves with his or her 'restaurant meme' once more confirmed, and thus replicated; the same goes for the restaurateur. On the other hand, the model accounts easily for innovation. A meme that is never realized in interaction will presumably decay, while, on the other hand, the actor exposed to a new situation, in interaction with people who have an encoded map of its script, is likely to quickly learn the complementary exigencies, and thus the memetic representation of the organization is adapted to prepare the actor for subsequent encounters of a similar kind. (Note that the learner acquires, not the same code as the first, but the complement.)

The self-organizing properties of the system

The internal dynamics of the cell include, of course, much more than the reproductive activities of the genetic system. That which explains the importance of the latter is that it accounts for the production of proteins, among which are to be found the enzymes that then become active agents in organizing the life of the cell and assuring the continuation of the reproductive cycle. We would argue that the function of communication, with respect to organization, is similar, in that it is by communication that the material preoccupations of organizational members are shaped, while at the same time the communication folds back onto itself, as Giddens proposes, to assure that the organizational pattern is replicated, and organization thus persists over time, and across space - the structurational hypothesis.

The organization is the cell

Under this hypothesis the organization *is* the cell of social life. Society is thus multi-cellular. An issue that the limits of this paper do not allow us to consider is that of how to establish the boundaries of the organization (for elaboration see Taylor & Van Every, forthcoming).

Conclusion

In Dawkins' initial treatment of memes he referred to them as "unit[s] of information residing in the brain" (p. 109) and described their propagation as "leaping from brain to brain via a process which, in the broad sense, can be called imitation" (p. 192). In a general way this is still how memes are principally conceived. Calvin (1996), for example, describes memes "as those things that are copied from mind to mind...from words to dances" and gives as examples advertising jingles and rumors (p. 18). Deacon (1997) similarly describes them as "bits of copied cultural information" (p. 115). In general, memes are seen to correspond to a cognitive pattern (or

"cerebral code" in Calvin's terms) and the spread of memes as a phenomenon of pattern cloning in the brain.

There are, as we see it, two principal problems with this way of characterizing the replication of memes. First, compared to genetic theory, it leaves the mechanism of imitation largely unspecified as a precise operation. It fails to explain why some patterns spread and some do not (an issue that has formed the matter of diffusion theory for more than a half century without producing any definite conclusion other than communicational). Second, it takes no account of the complementarity of patterns which, as the restaurant script illustrates, is an essential feature of cultural persistence. This latter omission may be traced to the dominance in memetic theory of considerations of cognitive dynamics and the relative neglect of communication. What we believe is that a reconsideration of the memetic *problématique* taking account of the role of language in communication provides both a more satisfactory explanation of the reproductive cycle, and a better account of the relation of memes to cultural persistence, as well as change.

It is obvious that such a theory will have to take account of non-linguistic as well as linguistic patterning: cooking and playing the violin as well as conversing. This does not seem to us an insuperable extension of the theory, but it is not one we have the space to consider here. Stated very generally, the issue is not of how memes "leap from brain to brain" but how they connect up with practice and thus become reinforced (or decay) by either having, or not having, an application. Any memetic pattern that is not, to use Weick's term, enacted is unlikely to survive. The spreading of a meme is thus not a "leap" but is inevitably mediated by practice.

MUTATION, SELECTION, AND VERTICAL TRANSMISSION OF THEISTIC MEMES IN RELIGIOUS CANONS

By

Abstract

A study of ancient and modern Near Eastern religious canons reveals the mutation, selection, and vertical transmission of fitness-enhancing textual units, defined as theistic memes. The earliest recorded theistic memes dealt with human fear of death and defined man's earliest relationship to god. Theistic memes that could theoretically affect fitness through selection and incorporation into religious canons included those dictating beliefs about (a) self-awareness in an unknown world, (b) strategies and behaviors toward others and within the nuclear family, and (c) appropriate sexual behaviors within marriage. Prohibition of aberrant sexual practices such as incest, adultery, homosexuality, bestiality, castration, and religious prostitution would have further maximized fitness. A remarkable mutation of the ancient Near Eastern theistic meme of child sacrifice is documented in the Old Testament in the story of Abraham and Isaac. Vertically transmitted theistic memes in the Hebrew canon were largely incorporated into Christian and Muslim religious canons (New Testament and Qur'an). Mutations of theistic memes during vertical transmission into these other canons allowed the same fitness-enhancing stability for the gentile and Arabic populations and are notable for the different strategies used to produce homogenized, orthodox canons.

Keywords: Religious canon, fitness, meme, mutation

1 Introduction

Dawkins (1976) coined the term *meme* (from the Greek *mimeme*, meaning "imitation") to describe a unit of cultural transmission. A meme serves as a memory device that can be propagated from person to person and from generation to generation in the form of spoken or written words or by example. Memes include ideas, knowledge, and concepts. Blackmore (1999) has further defined the meme as having properties that convey memory, can randomly vary, and are subject to selection. Heylighen (1998) has outlined the selection criteria necessary for memes to be successfully propagated from generation to generation. In the first step of meme propagation, *assimilation*, the meme must be assimilated and accepted by a host through infection (exposure) and must be somewhat plausible. In the next step, *retention*, the meme must be retained by the host through memory. With this step meme selection occurs. Without memory, a meme is extinguished and cannot proceed to the next step, *expression*, when infection of another host may occur. Retention of a meme depends on the perceived usefulness, interest, and relevance to the host. The last step is *transmission*, the physical means by which the meme

can be conveyed to the next potential host. Transmission may occur through physical gestures (hand or facial movements), speech, the spoken or written word, or pictures.

Memes that convey dictated social behavior can be categorized as either secular or theistic. According to Dawkins (1976), the *god meme* concept "provides a superficially plausible answer to deep and troubling questions about existence." Blackmore (1999) recognizes that religions contain memes that regulate certain behaviors, including sexual practices and some cooperative behaviors, and can modify aggression. Operationally, in most religious canons the god meme consists of a number of explicit pronouncements and commandments purportedly attributed to a god. In this study, these specific attributes and dictated behaviors are called *theistic memes*.

The word canon is derived from the Greek *kanon*, meaning "reed" or "cane," a device used by the ancients to ensure correct measurements in masonry. The term came to signify an act of setting standards, and by the fourth century implied a list of orthodox texts (Mellor 1972). Although the term was first used to describe the Christian literature, canonization can be documented in the earliest traditions of religious texts. A process in which those exercising authority in a population select and exclude material in written texts, thus developing a non-contradictory religious canon with coherent theistic memes, has occurred since the time of the ancient Babylonians. In general, theistic meme selection is attenuated over time as the text hardens into inviolable canon. Here, *religious canon* is defined as consisting of theistic memes faithfully transcribed from generation to generation. In the genesis of a canon or orthodox literature, after an initial period of competing theistic memes one group eventually prevails over others. Theistic memes may *mutate* as accidental or intentional alterations. Accidental alterations include misspellings, deletions, or repetitions. Ehrman (1993) has categorized intentional alterations as harmonization of the text with parallel passages, elimination of grammatical errors, or the smoothing out of ambiguities. However, in some instances the author of the alterations has the sole intention of creating text to render a canon more orthodox and does this by importing biased memes or by modifying or eliminating memes with contrary or competing views.

2 First Evidence of Memes

Schmandt-Besserat (1986) described the first definitive evidence of the creation of tangible objects, or *tokens*, as memetic devices designed to convey ideas among fellow humans. Tokens were used widely throughout the Near East from 8000 BCE onward. During this era of nascent agrarian cultures, societies required means of keeping records and indicating weights and measures to deal with the realities of increased food stores. Tokens were made from fired clay in simple geometric shapes -spheres, discs, cylinders -and used as mnemonic devices representing units of tangible goods. These tokens are the first evidence of tangible memes created to convey messages over distance and time.

Around 4000 BCE, more sophisticated memes were developed as *complex tokens*, clay figures with inscriptions indicating some abstract idea. Complex tokens originated at about the same time and location as Sumerian writings in the form of *cuneiform text*, some of which have survived to this day. The oldest writing identified to date (around 3500 BCE) is on a small limestone tablet excavated from the ancient city of Kish (Finegan 1979). Pictographs of a human head, hand, and foot and a threshing sledge appear on both sides of the tablets. The message

inscribed is as yet undecipherable. One of the first deciphered texts on a Sumerian writing tablet describes a hero named Enmerkar who ruled the city Uruk and lamented for a world of the past in which there was no fear (Kramer 1972a, 1972b).

*In those days there was no snake, there was no scorpion, there was no hyena,
There was no lion, there was no wild dog, no wolf,
There was no fear, no terror,
Man had no rival.*

This, one of the oldest recorded memes discovered to date, expresses the human belief in an imagined past when man was without anxiety, without fear, and without enemies who would do him harm. These Sumerian memes, preserved in clay, were meant to be read by others and were likely understood by many succeeding generations.

3 First Theistic Memes in Religious Canons

3.1 *Epic of Gilgamesh*

The earliest theistic memes to pass from generation to generation over a large territorial area are those found in the *Epic of Gilgamesh*. Tigay (1982) found the origins of the story in third millennium Sumeria; it was propagated to the old Babylonian empire (2000 BCE), the Hittite and Hurrian empires in the Middle Babylonian period (1400 BCE), and the Assyrian empire (700 BCE). This epic in its basic form, passed as a written document on clay tablets, was most probably read to the illiterates of the population, who then passed on the story in some oral tradition. Because the story was committed to a written form and was copied faithfully by learned scribes, the epic has been preserved for thousands of years. The *Epic of Gilgamesh* is a remarkable collection of theistic memes vertically transmitted over the centuries as a story of human fear of death and how humans should cope with death anxiety.

Gilgamesh, after the death of his best friend, Enkidu, finds himself crying "bitterly like unto a wailing woman." For seven days and nights he weeps over his friend, not permitting his burial. Grief stricken, he becomes obsessed with the fear of death: "When I die, shall I not be like unto Enkidu?" He eventually decides that he wants to find immortality and sets out to discover the dwelling place of Utnapishtim, the survivor of the Great Flood, who will be able to tell him how to achieve eternal life.

At the edge of the sea, Gilgamesh receives advice about his quest from Siduri, the divine barmaid.

*The life you pursue you shall not find,
When the gods created mankind.
Death for mankind they set aside.
Life in their own hands remaining,
As for you, Gilgamesh, let your belly be full,
Make merry day and night.
Of each day make a feast of rejoicing,*

*Day and night dance and play! Let your garments be sparkling fresh,
Your head be washed; bathe in water,
Pay heed to a little one that holds your hand.
Let a spouse delight in your bosom,
For this is the task of a woman.*

Gilgamesh eventually finds Utnapishtim, who recounts in detail the Great Flood, his survival, and the subsequent gift of immortality. Utnapishtim reveals the secret of the gods: at the bottom of the sea is a plant that gives eternal life. Gilgamesh departs in a boat, dives to the bottom of the sea, and retrieves the plant. But a serpent rises up from the water, smells the fragrance of the plant, and eats it. Gilgamesh weeps bitterly, but he realizes that nothing can be done to obtain immortality.

The Gilgamesh epic is a collection of ancient Near Eastern written theistic memes that expressly deal with questions about the fear of death and the afterlife. The instructions of the barmaid are a set of memes defining social strategies by which man is supposed to live his life. These memes are explicit: "The life you pursue you shall not find, / When the gods created mankind. / Death for mankind they set aside . . . / Pay heed to a little one that holds your hand. / Let a spouse delight in your bosom."

Oral traditions are believed to have preceded the written memes of the *Epic of Gilgamesh*. Tigay (1982) has documented the canonization of the Epic by comparing surviving clay tablets from different locales and chronological eras (Table 1). Gilgamesh, the Sumerian king, is believed to have lived around 2700 bce. Historical evidence suggests that Gilgamesh rebuilt a shrine to the god Enil at Nippur and constructed a wall at Uruk. The earliest texts concerning Gilgamesh date to 2100-2000 bce, and these were likely based on oral memes transmitted from the time of his reign. The original Sumerian tales included six non-interrelated compositions describing the true Sumerian hero king, Gilgamesh (Kramer 1972a, 1972b). The composition and meter of the tales suggest that they may have served as hymnic doxologies used in temples as part of hero worship of an ancient king. At this time Gilgamesh was considered part god. Although each tale had separate plots, three of the tales concerned Gilgamesh's fear of death and his wish to find eternal life.

Passage	Change from	Change to	Meme mutation type
Gilg. P. i, 7/ <i>GE</i> I,v,28	Descended upon me	Keeps descending	Synonyms or words functioning similarly
/ <i>GE</i> II, ii, 40	The populace gathered around him	The populace <i>jostles toward</i> him

Table 1: Theistic Memetic Mutations in the Gilgamesh Epic from Old Babylonian to Late Version (Adapted from Tigay 1982)

The transformation of the Sumerian tales into a religious canon began in the Old Babylonian period (2000-1600 BCE). The broad memetic story line of the Sumerian tales was creatively adapted into an integrated and well-meshed text with a definitive message. The central theistic memetic message was Gilgamesh's anguish over the death of a friend, his own fear of death, and

his search for immortality. The proto-theistic memes of the Sumerian tales were mutated. Enkidu changes from a servant to a friend, thereby increasing the emotional impact of his death on Gilgamesh. Added to the story were the all-important theistic memes of ancient Sumerian wisdom sayings, admonishing Gilgamesh to concentrate on his present earthly life, with a woman and children, and not to worry about immortality.

The Old Babylonian *Epic of Gilgamesh* spread throughout the ancient Near East in the Late and Middle Babylonian period. The canon was found in the original Akkadian and translated into Hittite and Hurrian, at which point the text was subjected to contemporary editing. These textual mutations were mostly in the form of unintentional scribal errors. However, some of the redaction included grammatical and lexical changes, addition of new words or phrases, or expansion of some ideas by parallelism. Some changes in the text included the addition of new ideas and some reflected changing religious ideology (Table 1). These mutations were incorporated into the text, which thereafter became standardized canon. The theistic memetic message of the *Epic* was probably relevant to populations throughout the ancient Near East, as it was widely distributed and considerable effort was put into preserving the text by meticulously copying it onto tablets.

The story of the Great Flood has ancient roots. Many early texts referred to the event(s) (Table 2), and the actual flood most likely occurred in the early third millennium. Two prominent early accounts were the Sumerian *Deluge* and the Akkadian *Atrahasis Epic*. Neither was incorporated into the Old Babylonian version. However, The *Atrahasis Epic* continued to be transcribed as independent canon until late in the first millennium (around 1250 BCE), when it was incorporated nearly verbatim into the *Epic of Gilgamesh*, greatly expanding the Utnapishtim flood story.

	<i>Gilgamesh Epic</i>	<i>Old Testament</i>
Author	Enlil, the Sumeria god of Babylonia.	God
Reason	In (Tablet XI:14) the heart of the great gods prompted them to bring a deluge	In (Gen. 6:1-13) The earth was corrupt before God and was filled with violence because of man, for all flesh had corrupted its way upon the earth.
Hero	The Summerian account calls him Ziusudra meaning "he who laid hold on life of distant days." Other versions call him Atrahasis meaning "the exceedingly wise."	Noah meaning "rest.". (Gen. 6:9).
Announcement	Ea appears to the Utnapishtim telling him to abandon his possessions and to build a ship with certain specifications and take into it every seed of life. (Tablet XI:19-31). This revelation was made contrary to Enlil's plan and without his knowledge. (Tablet XI:173).	In(Gen7:1), God communicates with Noah. "Go into the ark, you and your whole family, because I have found you righteous in this generation."

Period of Grace.	There was no thought of granting mankind an opportunity to repent. According to Atrahasis Epic man was granted several periods of grace before Enlil determined to destroy humankind by means of a flood.	Gen. 6:3, Man was granted period of grace one hundred and twenty years.
Ark and Dimensions	Elippu, meaning "a great vessel," "boat," "ship." Utnapishtim's boat, length height, and width were 120 cubits, seven stories.	Ark is "teba" related to the Egyptian db't meaning, "box," "chest," "coffin." Noah's ark was "three hundred cubits, its breath fifty cubits, and its height thirty cubits" (Gen. 6:15). Noah's ark had 3 stories.
Occupants	Utnapishtim loaded aboard all he had of "the seed of all living creatures," "the game of the field, the beasts of the field, all the craftsmen," (Tablet XI: 80-85 and 94-95).	Gen. 6:19-21: "of every living thing, of all flesh, thou shalt bring two of every into the ark to keep them alive with thee; they shall be a male and a female. Of the birds....." "And Noah, with his sons, his wife, and the wives of his sons, went into the ark, because of the waters of the flood."
Flood Begins	Tablets silent on this point.	"In the sixth hundredth year of Noah's life, in the second month, on the seventeenth day of the month, on that very day all the fountains of the great deep (tehom) were broken open, and the windows of the heavens were opened" (Gen. 7:11).
Cause	The destructive forces listed in the Sumerian tablet are amuru, meaning "rainstorm," "rain flood," or "cloudburst," and mighty winds. These two elements accompanied by thunder and lightning are mentioned in the Gilgamesh Epic.	Torrential rains from the heaven and the eruption of the subterranean waters. (7:11-12).
Duration	Rained in the evening followed by a storm that lasted for six days and six nights.	For forty days and forty nights it rained upon the earth. (Gen 7:11)
Storm magnitude	"As soon as the first shimmer of the morning beamed forth, a black cloud came up from out the horizon."	"The waters increased and lifted the ark, so that it rose above the earth....the waters grew exceedingly strong upon the earth; and all the mountains under the whole heaven were covered."
Ark Landing	Mount Nisir, "mount of Salvation."	"on one of the mountains of Ararat."

Bird Scene	Utnapishtim released a dove for testing the subsidence of the water on the seventh day after the landing at Mount Nisir.	Forty days after the tops of the mountains had become visible, Noah opened the window of the ark and sent forth a raven. (Genesis 8:5-7). Having waited seven more days, Noah released another dove, which did not come back until toward evening. (8:10-11) After another seven days, Noah sent out a third dove, but she never returned (8:12) Also this was a good sign; It showed that the lowlands as well as the mountains were free of water
Exit from the Ark	"sent forth to the four winds"	God said to Noah, "Go forth of the ark, thou and thy wife, thy sons and the wives of thy sons with thee. Bring forth with thee every living thing that is with thee....and be fruitful and multiply on the earth" (8:16-17)
Sacrifice	Utnapishtim prostrated himself before the sun-god and offered up an Ox and an abundant sacrifice of sheep.	Noah built an alter unto the Lord and offered burnt-offerings "of every clean beast and of every clean fowl" (8:20).
Divine Blessings	Removal from the ken of mortal man	Man may not be slain in impunity either by man or by beast (Gen. 9:1-7)

Table 2: Theistic Memes of Flood Story in the Gilgamesh Epic and Old Testament (Adapted from Heidel 1963)

3.2 Enuma elish

The Gilgamesh memes did not deal with questions about how gods and humans were created. These were recorded in a second set of written theistic memes found throughout the ancient Near East, called the *Enuma elish* (When above) myth. The memes incorporated in this myth likely date to the rise of the first Babylonian dynasty (1894-1595 BCE) when the god Marduk was legitimized, especially under the reign of Hammurabi (1792-1750 BCE), the most powerful of the Babylonian kings.

The creation story opens with a description of a time when there was nothing but the divine spirits, the parental gods, Apsu and Tiamat, and their son, Mummu. Each represents cosmic matter, different forms of water (fresh water, salt water, and clouds) that mingled together and from which light emanated and the universe was made. After several generations of gods, the great wise god, Marduk, is born; he becomes supreme by slaying the evil gods and creating man. This complicated story raised as many questions as it answered. However, as a memetic device it provided "an answer" to questions about creation that endured for centuries. Ultimately, the myth became logically untenable and was abandoned, but the basic memetic structure survives to this day in the Old Testament.

	<i>Enuma Elish</i>	<i>Passage</i>	<i>Genesis</i>
Tablet VII: 86	Divine Spirit and cosmic matter are coexistent and coeternal	Gen. 1:1-2	Divine spirit creates cosmic matter and exists independently of it
Tablet VI: 23-30	Primeval chaos; Tiamat enveloped in darkness	Gen. 1:2	The earth a desolate waste, with darkness covering the deep(tehom)
Tablet I: 38	Light emanating from the gods	Gen. 1:3	Light created
Tablet I: 59-72	The creation of the firmament	Gen. 1:6	The creation of the firmament
Tablets IV: 143-45	The creation of the dry land	Gen. 1:9	The creation of dry land
Tablet V: 1	The creation of the luminaries	Gen. 1:14-18	The creation of the luminaries
Tablet VI: 1-38	The creation of man	Gen. 1:26	The creation of man
Tablet VII	The gods rest and celebrate	Gen. 2:2	God rests and sanctifies the seventh day

Table 3: Theistic Memetic Structures in Enuma Elish Creation Myth and Old Testament Genesis (Adapted from: Heidel 1963)

A superficial comparison of the Hebrew Genesis and the Babylonian *Enuma elish* might suggest the two stories are different in style, complexity, logic, and maturity. However, Heidel (1942) demonstrated that when the internal memetic structures (story lines) are outlined, they prove to be identical (Table 3). The memetic influences of the *Enuma elish* were also found to have influenced the Canaanite population, with the creation of Baal paralleling the genesis of Marduk. This parallelism is also evident in the stories that deal with the struggles of Tiamat and the struggles of Yahweh in slaying the primordial evil monsters. These two texts are likely memetic homologues.

When thou shalt smite Lotan, the fleeing serpent, And shalt put an end to the tortuous serpent, Shalyat of the seven heads.
(Ras Sharma Tablets)

On that day the Lord will punish with His sword, which is hard and great and strong, Leviathan, the fleeing serpent, and Leviathan, the tortuous serpent, And He will slay the crocodile that is in the sea.
(Isa. 27:1)

And theistic memes as hymns of praise for Baal were most likely memetically mutated in form and context to become Psalms for the Hebrew God, Yahweh.

*Behold, thine enemies, O Baal;
Behold, thine enemies thous shalt smite.
Behold, thou shalt destroy thine adversaries.
(Ras Sharma Tablets)
For, behold, thine enemies, O Lord,
For, behold, thine enemies shall perish!
All the workers of iniquity shall be scattered!
(Ps. 92:10)*

3.3 Law Codes

The third widely distributed written tradition of memes passed from generation to generation in ancient Near Eastern cultures consisted of sets of law codes. Some codes date to the Sumerian period, the laws of Ur-Nammu (2112-2095 BCE). Not all the Ur-Nammu law codes were preserved, and the number and subject and the punishments decreed by the king cannot be known.

The law code memes were presented as divinely inspired and were preceded by a prologue establishing the authority of the king and his relationship to the gods. Thus the laws had a basis and a credibility in the population as enforced by the gods. These are therefore theistic memes. An epilogue details punishments for those who chose to disobey or deface the inscribed codes. In the code of Hammurabi, the chief god, Enlil, proclaims

When lofty Anum, king of the Anunnaki, and Enlil, lord of heaven and earth, the determiner of the destinies of the land, determined for Marduk, the first-born of Enki, the Enlil functions over all mankind, made him great among the Igigi, called Babylon by its exalted name, made it supreme in the world, established for him in its midst an enduring kingship, whose foundations are as firm as heaven and earth--at that time Anum and Enil named me to promote the welfare of the people, me Hammurabi, the devout, god-fearing prince, to cause justice to prevail in the land, to destroy the wicked and the evil, that the strong might not oppress the weak, to rise like the sun over the black-headed people and to light up the land.

The memetic law codes of Eshnunna and Hammurabi were directly incorporated into the *Covenant codes* of the Torah (Mellor 1972, Patrick 1985). Mellor (1972) has noted some thirty-five to fifty Covenant memetic codes that are directly related to the Hammurabi memetic codes. Finkelstein (1981) has provided convincing evidence of direct meme transfer from Near Eastern codes to the Hebrew laws dealing with the issue of the goring ox. Early agricultural populations depended on oxen for heavy labor. The ox, although useful for many tasks, was also unpredictable and capable of inflicting injury by goring its owner or others. The people of the ancient Near East understood that some oxen were prone to goring innocent bystanders and that the owners of these oxen should be aware of this and should take appropriate protective measures. Owners who did not do so were guilty of "culpable negligence," a concept that ancient Near Eastern populations thought worthy of setting into theistic memetic laws to be passed from

generation to generation. These laws are notably found in three codes, the Eshnunna, the Hammurabi, and the Covenant.

Oxen memetic laws of Eshnunna, 1850 BCE:

If an ox has gored another ox and caused its death, the owners of the oxen shall divide between them the sale value of the living ox and the carcass of the dead ox.

If an ox was a habitual gorer, the local authorities having so duly notified its owner, yet he did not keep his ox in check and it then gored a man and caused his death, the owner of the ox shall pay two thirds of a mina of silver to the survivors of the victim.

If it gored a slave and caused his death, he shall pay fifteen shekels of silver.

Oxen memetic laws of Hammurabi, 1792-1750 BCE:

If an ox, while walking along the street, gored a person and caused his death, no claims will be allowed in that case.

But if someone's ox was a habitual gorer, the local authority having notified him that it was a habitual gorer, yet he did not have its horns screened nor kept his under control, and that ox then gored a free-born man to death, he must pay one-half mina of silver.

If the victim was someone's slave, he shall pay one-third mina of silver to the slave's owner.

Oxen memetic laws in Covenant code (Exod. 21:28-32), 1200-1000 BCE:

If an ox gores a man or a woman to death, the ox shall be stoned to death, its flesh may not be eaten, but the owner of the ox is innocent.

But if the ox was previously reputed to have had the propensity to gore, its owner having been so warned, yet he did not keep it under control, so that it then killed a man or a woman, the ox shall be stoned to death, and its owner shall be put to death as well. Should a ransom be imposed upon him, however, he shall pay as the redemption for his life as much as is assessed upon him. If the ox gore a slave or slavewoman, he must pay thirty shekels of silver to his owner, but the ox shall be stoned to death.

If an ox belonging to one man gores to death the ox of his fellow, they shall sell the live ox and divide the proceeds, and they shall divide the dead one as well.

But if the ox was previously reputed to have had the propensity to gore, and its owner had not kept it under control, he shall make good ox for ox, but will keep the dead one for himself.

The interrelationships among these texts are unmistakable. Given the identical memetic expressions and situations, it is highly likely that the laws of Eshnunna and Hammurabi were directly related to or drew upon the same prototypical material. The Hebrew writers likewise

undoubtedly knew of the culpable negligence meme and the written Mesopotamian memetic codes, those concerning oxen in particular, when mutating these laws to craft the Covenant code.

4 Theistic Memetic Creation of the Hebrew Canon

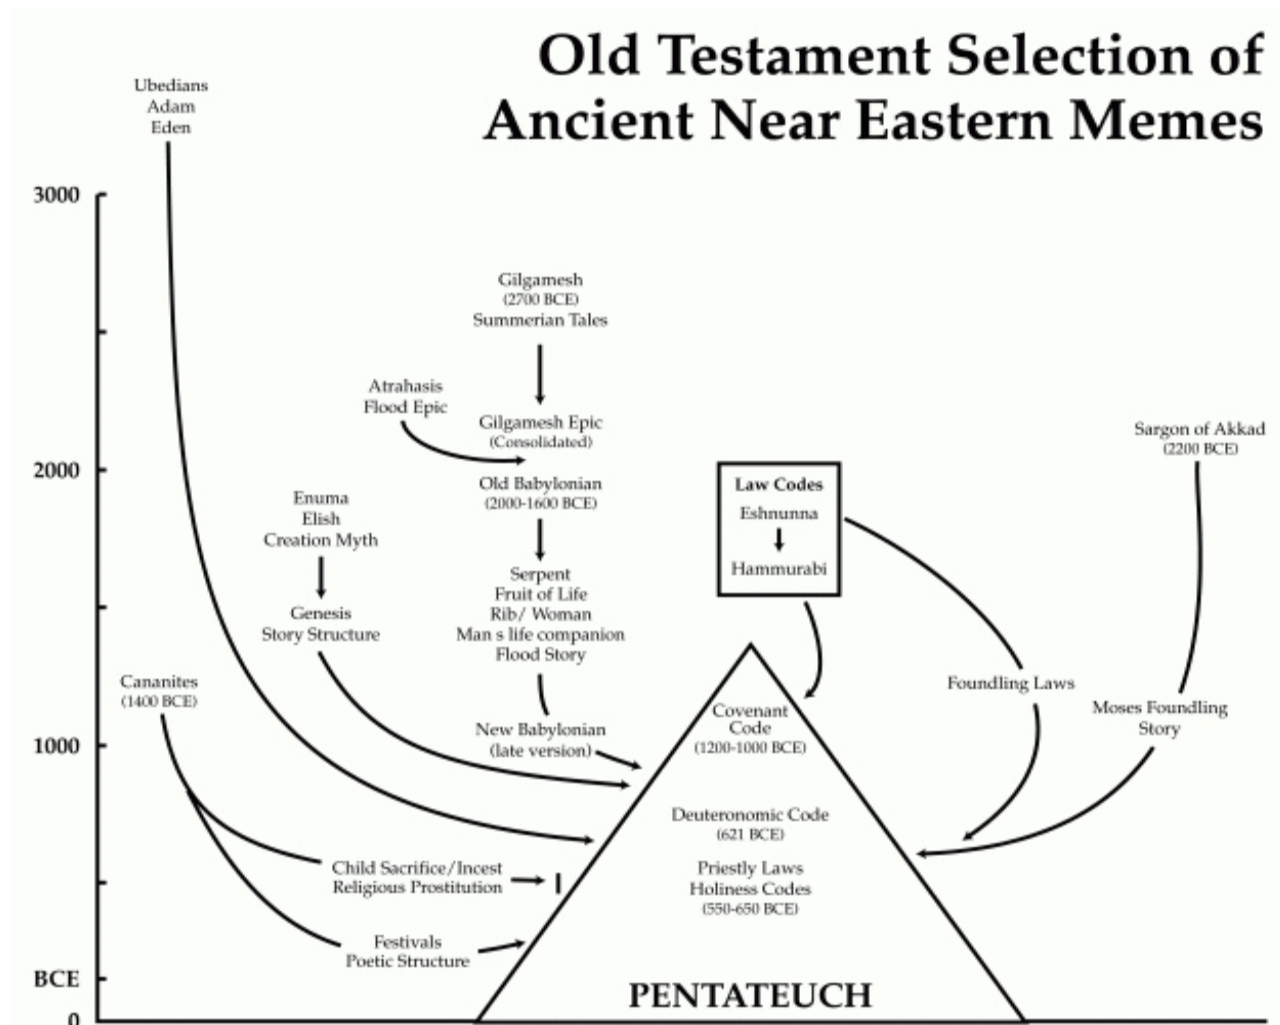

Table 4: Old Testament Selection of Ancient Near Eastern Memes

A number of theistic memes taken from Mesopotamian canon and other traditions were selected and incorporated into the Hebrew canon, the Pentateuch (Table 4). The advice of the Siduri to Gilgamesh found in Tablet X of the Old Babylonian version is incorporated into Ecclesiastes 9:7-11 as:

*Go then eat your bread in happiness and drink your wine with a cheerful heart; for God has already approved your works.
Let your clothes be white all the time, and let not oil be lacking on your head.*

Enjoy life with the woman whom you love all the days of your fleeting life which He has given to you under the sun; for this is your reward in life and in your toil in which you have labored under the sun.

Whatever your hand finds to do, do it with all your might; for there is no activity or planning or knowledge or wisdom in Sheol where you are going.

I again saw under the sun that the race is not to the swift and the battle is not to the warriors, and neither is bread to the wise nor wealth to the discerning nor favor to men of ability; for time and chance overtake them all.

(Segal in press)

Hamblin (1987) has described what may be the oldest memetic story, Adam in the Garden of Eden (probably of pre-Sumerian in origin), as representing man's transition from hunter-gatherer to agriculturist some 7000 years ago. The terms *Adam* and *Eden* have been found in cuneiform texts from early Sumerian times and even the earlier Ubaidian period. *Eden* means fertile plain; *Adam* means settlement on the plain. God's banishment of Adam and Eve from the Garden of Eden has been proposed to represent humans' choice of a life of husbandry and agriculture over their earlier, God-ordained life as hunter-gatherers, thus going against "God's will." The "original sin" may in fact have been the choice to grow our own food. The serpent that presents the gift of knowledge is no doubt a memetic mutation of the sea serpent that steals the immortality-giving plant in the *Epic of Gilgamesh*. Also taken from the *Epic of Gilgamesh* (previously the Atrahasis epic) is the theistic meme of the flood story; importantly, Noah becomes the memetic figure Utnapishtim. Heidel (1970) has shown the remarkable and unmistakable parallels between these two stories, including the characters, the ark, and the sequence of events (Table 2). Another likely theistic meme taken from the *Epic of Gilgamesh* and incorporated into the Genesis canon is the concept of a man's life companion. The author of the *Epic* chose a man, Enkidu, for Gilgamesh's companion. The author of the Hebrew Genesis mutated this memetic concept such that a woman becomes a man's life companion.

Of great importance to the Torah is the story of Moses. His early life in the Egyptian court is recounted in detail in Exodus. However, the story of a foundling who is rejected, exposed to danger, and found and nurtured and then grows to adulthood to achieve greatness was a literary meme first used to describe the early life of Sargon of Akkad (2371-2316 bce) (Table 4). Sargon was one of the first great conquerors of history. As Finegan (1979) recounts the legend, Sargon's mother puts him in a basket made of rushes and floats it down a river. The boy is pulled out of the water by a woman named Akki, who raises him in the court of the king Ur-Zababa. Sargon breaks away and establishes his own kingship, eventually capturing and uniting the Sumerian and Akkadian kingdoms. Childs (1965) has pointed out that Sargon of Akkad initiated the founding child legal principles, articulated in the earliest of the ancient Near Eastern law codes and later incorporated into the Old Testament. These principles included statements of (a) the individual involved, (b) length of time designated by the contract, (c) condition of work, (d) specifications about nourishment, (e) fines for breach of contract, (f) amount of wages, and (g) witnesses. The narrative of the Moses foundling story incorporates these ancient Near Eastern legal memes (except for the breach of contract clause) in this order.

Then said his sister to Pharaoh's daughter, Shall I go and call to thee a nurse of the Hebrew women, that she may nurse the child for thee? And Pharaoh's daughter said unto her, take this child away and nurse it for me, and I will give thee wages. And the woman took the child and nursed it. And the child grew, and she brought him unto Pharaoh's daughter, and he became her son.

(Exod. 2:7-10)

The Hebrew writers were not unlike the ancient Near Eastern authors of the *Epic of Gilgamesh*, who understood that a text could be revised and reinterpreted to edify and reconcile new historical and theological events. The Hebrews' examination and probing of these new events to find relevant precedence was called *Midrash*. Midrash was employed in the development of new text as a creative inspiration based on a knowledge of previous texts and traditions (Goulder 1974). Midrashic activity was rationalized by the Hebrew belief that one passage could be used to illuminate another, whether a simple or a complex passage. Deuteronomy is essentially a Midrash of the Covenant code; Chronicles is a Midrash of Kings. Thus in essence, Midrash was the process of theistic memetic mutation that allowed a successful meme to be varied and incorporated into new text. If a new text was accepted as canon, the incorporated, mutated theistic memes could (and frequently did) affect reproductive fitness. Thus the Hebrew literature is an interwoven fabric of theistic memetic historical facts, traditions, beliefs, and rituals. These texts were often related to others by Midrash, or the incorporation of theistic memetic mutations.

The overriding Hebrew theistic meme was that all humans are created in God's image and thus all are created equal (Dimont 1962, Johnson 1988). This theistic meme was distinct and unique in ancient Near Eastern traditions because of its emphasis on human life and the rights of individual believers - a concept that contrasted with other contemporary cultures in which property rights and the rights of royalty were paramount. In the goring oxen memes of the Hebrews, the emphasis on punishment conveyed the importance of human life, whereas in the analogous Babylonian culpable negligence memes the emphasis was on property rights.

The fully developed Jewish text of laws, the Torah or Pentateuch, in its complete form consists of 613 theistic memes, faithfully preserved to this day (*Encyclopaedia Judaica* 1971). These theistic memes accrued over a number of centuries to cover a vast array of codes of conduct defining behavior and beliefs. The codes were interpreted literally, without a well-defined belief in the afterlife, until the first century bce, when several sects developed alternative memes about how the law could be reinterpreted.

Jewish religious canon evolved in three distinct phases, the Covenant code (1200-1000 bce), as discussed above, the Deuteronomic code (700-621 bce), and the Holiness code (587-450 bce). The Deuteronomic code was likely developed in the century before its fabled discovery in the Jerusalem temple during Josiah's reign (621 bce). The Deuteronomic laws were intended to further restate and redefine Hebrew monotheism and to rid the religion of foreign influences by actively repudiating the customs and practices of the Canaanites and the Egyptians. The Canaanite civilization was eventually subjugated, with the land and people incorporated into the Hebrew state. Some of the religious practices of the Canaanites were incorporated into the religious beliefs of the Hebrews, such as worship of the Canaanite gods and the practice of child

sacrifice. The Deuteronomic code amply documents later Hebrew writers' attempts to repudiate these Canaanite cultic practices related to child sacrifice, fertility, and religious prostitution.

You shall not behave thus toward the Lord your God, for every abominable act which the Lord hates they [the Canaanites] have done for their gods; for they even burn their sons and daughters in the fire to their gods.
(Deut. 12:31)

When you enter the land which the Lord your God gives you [Canaan], you shall not learn to imitate the detestable things of those nations. There shall not be found among you anyone who makes his son or his daughter pass through the fire, one who uses divination, one who practices witchcraft or one who interprets omens, or a sorcerer.
(Deut. 18:9-10)

Child sacrifice must have markedly reduced the fitness of the Canaanites. This behavior was clearly "imitated" by the Hebrews and would have markedly reduced their fitness as well.

They [the Israelites] did not destroy the peoples, as the Lord commanded them, but they mingled with the nations and learned their practices, and served their idols, which became a snare to them. They even sacrificed their sons and their daughters to the demons, and shed innocent blood, the blood of their sons and their daughters, Whom they sacrificed to the idols of Canaan.
(Ps. 106:34-37)

The Hebrew practice was later seen as an "abomination" in the eyes of God: "They [Israelites] built the high places of Baal that are in the valley of Ben-hinnom to cause their sons and their daughters to pass through the fire to Molech" (Jer. 32:35). King Josiah destroyed this child sacrificial alter, called a Topheth: "[King Josiah] also defiled Topheth, which is in the valley of the son of Hinnom, that no man might pass his son or his daughter through the fire for Molech" (2 Kings 23:10). And Jeremiah (7:30-32) records,

For the sons of Judah have done that which is evil in my sight declares the lord, they have set their detestable things in the house which is called by My name to defile it. They have built the high places of Topeth, which is in the valley of the son of Hinnom, to burn their sons and their daughters in the fire, which I did not command, and it did not come into My mind. Therefore, behold, days are coming, declares the Lord, when it will no more be called Topeth, or the valley of the son of Hinnom, but the valley of the Slaughter; for they will bury in Topeth because there is no other place.

Ultimately, Jewish fitness was enhanced by the absolute prohibition against child sacrifice. No religious practice, except suicide and prohibition against heterosexual sex, could limit fitness more. Human child sacrifice must be a non-genetically driven behavior, a practice dictated by religious mandate. Development of a genetically driven human behavior that would waste such an extraordinary amount of parental investment is improbable. The practice probably evolved as a phenomenon of self-awareness that imagined a vengeful god who would unleash the most horrible of unknowns if not appeased with the ultimate sacrifice -one's own child. The meaning of the story of Abraham and Isaac has baffled many. How could any father be so willing to

sacrifice his own son, even if asked by God? However, in the times of the ancient Near Eastern Canaanites and Israelites, sacrifice of a child was the only way to truly gain favor and to spare the wrath of God. As Maccoby (1982) concludes,

Perhaps the most interesting story [about human sacrifice], however, is the story of Abraham and Isaac, for here we find not complete transformation, made from an anti human-sacrificial stand-point, but a phase transition, in which the yearning for human sacrifice is still struggling with the desire to abolish it. The purpose of the story is to show that God Himself ordained that animal sacrifice should be substituted for human sacrifice. At the same time, the story contains no moral revulsion from the very idea of human sacrifice. On the contrary, it is imputed to Abraham as extraordinary merit that he was willing to sacrifice his favourite son, Isaac, at the behest of God. We see here the dynamics of the historic move from human to animal sacrifice: on the one hand, this is a revolutionary step, by which a higher morality is brought into effect; on the other, the benefits of human sacrifice cannot be lightly relinquished, and the transition from human to animal sacrifice must appear plausible in the sense that animal sacrifice must acquire the same aura of reverence and holiness that previously belonged to human sacrifice.

In effect, the story of Abraham and Isaac represents a transition of the Hebrews to a more fit religious population through the memetic mutation of their religious canon to exclude the fitness-reducing practice of child sacrifice.

After the Babylonian exile, the Hebrew canon was further infused with fitness-enhancing memes that came to be known as the *Holiness code*. The overall effect of the Holiness code was to make the Hebrew population more a religious community than a nation-state. Although many of the theistic memes were related to ritual and sacrifice, a substantial number were direct and explicit sexual prohibitions. Many Canaanite sexual practices (incest, bestiality, and prostitution) were detrimental to maintaining the nuclear family and most likely contributed to the population's decline in fitness. In contrast, the Holiness code prohibited incest, with the most inclusive set of theistic memes to counter consanguinity. Laws also prohibited adultery, homosexual sex, and bestiality. These Jewish theistic memetic laws greatly enhanced fitness and were enforced by the most explicit (attributed to God) theistic memetic punishments.

Defile not ye yourselves in any of these things: for in all these the nations are defiled which I cast out before you: And the land is defiled: therefore I do visit the iniquity thereof upon it, and the land itself vomiteth out her inhabitants. That the land spew not you out also, when ye defile it, as it spewed out the nations that were before you. For whosoever shall commit any of these abominations, even the souls that commit them shall be cut off from among their people. Therefore shall ye keep mine ordinance, that ye commit not any one of these abominable customs, which were committed before you, and that ye defile not yourselves therein: I am the Lord your God.

(Lev. 18:24, 25, 28-30)

Here, human behaviors are dictated not by genes but by mental constructs backed up by another mental construct, the fear of God.

At the core of the fitness-enhancing Jewish canon are other unique theistic memes that allowed all individuals of the religious population to exercise and to be governed by the same behavioral memes. Collectively, the newly constituted theistic memes, as the *Laws of Israel*, facilitated the reproductive success of the entire population. Jewish theistic memes provided more credible answers than did other Near Eastern genesis stories to self-awareness questions such as: Where did I come from? Who is God? What happens when I die? When my family dies? Is there life after death? On this platform of increased credibility were established other theistic memes that facilitated reproductive success. Decreasing conflict among individuals was chief among the effects of these memes. The Hebrew God commanded, "Thou shalt not hate thy brother in thine heart: thou shalt not in any wise rebuke thy neighbor, and not suffer sin upon him. Thou shalt not avenge, nor bear any grudge against the children of thy people, but thou shalt love thy neighbor as thyself. I am the Lord" (Lev. 17, 18). The overall strategy had clearly shifted to cooperation for the whole population. Other theistic memes stabilized the nuclear family through strict laws on obedience to and respect for one's parents and the maintenance of the family through strict observance of religious ritual. Other remarkable theistic memes in the Jewish canon promoted the reproductive success and fitness of the population. The Law states that Jewish men and woman should marry and that as husband and wife they should have children.

5 Theistic Memetic Mutation in Creation of the Christian Canon

The *Sadducees* were an authoritarian group of Jewish priests and the well-to-do who proposed that all Law was to be written and that a strict and literal adherence to the Law was necessary to be holy and to be a Jew. The Law was not to be changed; it was fixed for all time. Because the Torah contained few specific memes regarding an afterlife, the Sadducees ignored the subject. In contrast, the *Pharisees* embraced the idea of an apocalypse and an afterlife, as recounted by Isaiah, and the concept that those who had fulfilled the Law and were denied compensation in this earthly life would be compensated in the next. The Pharisees proposed that if a person could not fulfill the Law literally because of penury or physical circumstances, then executing the spirit of the Law was sufficient. The *Essenes* were an ascetic sect on the fringes of Jewish society. They believed in resurrection, immortality of the soul, and a messiah who would lead the way to immortal salvation. The wicked would be punished in hell and the good would live with God in heaven. The Essenes developed elaborate purification rites, including baptism, in which new members were admitted into a "New Covenant" with the remission of sins. The messiah, the "Teacher of Righteousness," preached penitence, poverty, and love of one's neighbors. In this Jewish Essene church, the essential rite was the sacred meal. The Essenes believed in celibacy, yet permitted marriage. Most new members were adopted from other sects and indoctrinated in the faith.

A fourth Jewish sect was the *Christians* (Johnson 1988). Jesus of Nazareth, baptized by John the Baptist, an Essene, radically changed the interpretation of the Law: no longer were the historical context and roots of the Law important. Fulfillment of the Law, in fact, was comparable only to good works -just a precondition for eternal salvation. Salvation itself depended on faith and belief in Jesus as the Son of God, the fulfillment of the prophecy of the Jewish messiah. The theistic memes concerning Jesus Christ were that (a) he was the Jewish messiah, (b) he was crucified, and (c) he rose from the dead. The initial community that embraced Jesus as the new Messiah was Jewish and based in Jerusalem. Distinguishing the growth of this church from other

Jewish sects were memes that would be spread by a few gentile believers in Antioch. In a momentous decision by the ruling council of Jewish Christians in Jerusalem, gentiles were accepted into the faith without having to fulfill the initiation requirements to become a Jew (Acts 15; all references to the New Testament are to the Revised Standard Version.). Thus the uncircumcised gentile and the observant Jew were equal members in this new religion. Because the religion was so appealing to pagans in the Hellenized world and to the diasporic Jews, many became converts. Soon the vast majority of Christians were gentiles and, when the Jerusalem temple was destroyed by the Romans in 70 ce, all formal links to Judaism were severed. However, the Christian church was always to retain the central theistic meme, the belief in the God of Israel.

The Christians kept the theistic memes associated with the Hebrew God, Yahweh, as creator of the universe, earth, and humanity. In Matthew 5:17-20, Christ teaches his disciples:

Think not that I have come to abolish the law, or the prophets: I am not come to abolish them but to fulfill them. For truly, I say unto you, until heaven and earth pass away, not an iota, not a dot, will pass from the law until all is accomplished. Whoever then relaxes one of the least of theses commandments, and teaches men so, shall be called least in the kingdom of heaven, For I tell you, unless your righteous exceeds that of the scribes and Pharisees, you will never enter the kingdom of heaven.

Also retained were the theistic memes detailing Israelite history and the interpretations of this history by the Israelite God. These included the history of Moses and the giving of the Law and the history of the prophets and the kings. From the large amount of Jewish memetic law, the Christians appropriated the memes related to human equality and equal justice; theistic memes restricting holiness to those who could provide the elaborate, sacrificial rituals were selectively minimized. In Matthew 23:23 Christ expounds, "Woe to you, teachers of the law and Pharisees, you hypocrites! You give a tenth of your spice-minth, dill and cumin. But you have neglected the important matters of the law - justice, mercy and faithfulness. You should have practiced the latter, without neglecting the former."

Thus the theistic memes to be embraced and acted upon in order to achieve holiness were reduced in number, simplified, and in effect made available to any individual. The Christian theistic memes included behavior commandments attributed to Jesus (You must love your fellow human as yourself) and to his proselytizers. The Lord's prayer is a central Christian theistic meme, which appeals to the Jewish God, our Father, with adoration; the will of God is accepted, with a request for the basic necessities of life and a plea for forgiveness and the promise to forgive. Many Christian religions were to evolve from the initial followers of Christ in Jerusalem. The Church of Rome, the Byzantine or Eastern Orthodox Church, and the Protestant Church are some of the major Christian populations that adopted mutant theistic memes dealing with differences in beliefs, rituals, and behaviors.

Spong (1996) has catalogued the same process of theistic memetic mutation (Midrash) in the development of Christian canon. The Gospel writers, in attempting to legitimize the new Jewish messiah, used the Midrashic technique to ground Christ firmly in the prophecies and traditions of the Scriptures, or Old Testament. Many examples are evident (Table 5). Christian Midrash also

included the alteration of existing Gospel texts by later Gospel authors to harmonize and further legitimize Christ. The earliest written Synoptic Gospel was that of Mark. In writing of the parentage of Jesus, Mark does not mention an earthly father, referring to Jesus thus: "Is not this the carpenter, the son of Mary" (Mark 6:3). The lack of any reference to a father in any part of this Gospel would have opened Jesus to charges of being born a bastard. For Jews who considered Jesus the messiah this would have been a major obstacle: "A bastard shall not enter into the congregation of the Lord" (Deut. 23:2). The modifications or mutations made by Matthew when he copied Mark's text are obvious and transparent. When Matthew incorporated Mark's text on the parentage of Jesus, the text is transformed from "Is not this the carpenter, the son of Mary" into "Is not this the carpenter's son, whose Mother is called Mary" (Matt. 13:55). Thus, in this remarkable mutation of a theistic meme, Joseph is created as Jesus' father.

Crucifixion				
Passage	Old Testament Verse	Passage	New Testament Verse	Significance
Psalm 22 :1	My God, my God, why hast thou forsaken me? Why art thou so far from helping me, from the words of my groaning?'	Mark 15 :34 Matt. 27 :46	‘And at the ninth hour Jesus cried with a loud voice, "E'lo-I, E'lo-i, la'ma Sabach-tha'ni?" which means, "My God, my God, why hast thou forsaken me?"’ ‘And about the ninth hour Jesus cried with a loud voice, "Eli, Eli, la'ma sabach-tha'ni?" that is, "My God, my God, why hast thou forsaken me?"’	Midrashic description of the crucifixion based on Psalm 22. Nearly every element of the Psalm is used to depict the crucifixion seen. Here the cry, "My God, my God, why has thou forsaken me has been lifted word for word from the Psalm.
Psalm 22 :7-8	‘All who see me mock at me, they make mouths at me, they wag their heads; "He committed his cause to the LORD; let him deliver him, let him rescue him, for he delights in him!"’	Mark 15: 29 Matt. 27 :43	‘And those who passed by derided him, wagging their heads, and saying, "Aha! You who would destroy the temple and build it in three days,’ ‘He trusts in God; let God deliver him now, if he desires him; for he said, "I am the Son of God."’	Here the concept of someone divine in dire consequences mocked by others to save himself has been copied and mutated from Psalm 22.
Psalm 22 :17	‘I can count all my bones--they stare and gloat over me;’	John 19 :32-36	‘So the soldiers came and broke the legs of the first, and of the	Jesus, who had come to symbolize the perfect sacrifice as the

			<p>other who had been crucified with him; but when they came to Jesus and saw that he was already dead, they did not break his legs.’ ... ‘For these things took place that the scripture might be fulfilled, "Not a bone of him shall be broken."’</p>	<p>paschal lamb, had to be physically perfect as an offering and could not have any broken bones.</p>
Psalm 22 :15	‘ my strength is dried up like a potsherd, and my tongue cleaves to my jaws; thou dost lay me in the dust of death.’	John 19 :28	‘After this Jesus, knowing that all was now finished, said (to fulfill the scripture), "I thirst."’	The theme of thirst is continued to parallel Psalm 22.
Psalm 22 :18	‘they divide my garments among them, and for my raiment they cast lots.’	John 19 :23-24	‘When the soldiers had crucified Jesus they took his garments and made four parts, one for each soldier; also his tunic. But the tunic was without seam, woven from top to bottom; so they said to one another, "Let us not tear it, but cast lots for it to see whose it shall be." This was to fulfill the scripture, "They parted my garments among them, and for my clothing they cast lots."’	The text of Psalm 22 is further developed with the division of clothes and the casting of lots. The symmetries among the stories is now complete
<i>Virgin Birth</i>				
Psalms 2 :7	‘I will tell of the decree of the LORD: He said to me, "You are my son, today I have begotten you.’	Romans 1 :4	‘and designated Son of God in power according to the Spirit of holiness by his resurrection from the dead, Jesus Christ our Lord,’	The earliest of scriptural writings from Paul which designate Jesus as God’s son, a title that had been used for the Kings of Israel

Isaiah 7:14	Behold a young woman shall conceive and shall bring forth a son and you shall call his name Emmanuel, which means God is with us.	Matt 1:23	Behold a virgin shall conceive and shall bring forth a son and you shall call his name Emmanuel, which means God is with us.	Midrashic use of Isaiah 7:14 by Matthew to signify Jesus' virgin birth. Matthew did not realize that he had copied from a Greek translation that had improperly used "virgin" for "young woman".
Isaiah 42:1	'Behold my servant, whom I uphold, my chosen, in whom my soul delights; I have put my Spirit upon him, he will bring forth justice to the nations.'	Mark 1:11	'and a voice came from heaven, "Thou art my beloved Son; with thee I am well pleased."	The use of Midrash by Mark to signify the inauguration of Christ's as the "Son of God" to occur at his baptism
Psalms 110:4	'The LORD has sworn and will not change his mind, "You are a priest for ever after the order of Melchizedek."	Hebrews 7:1, 17	'For this Melchizedek, king of Salem, priest of the Most High God, met Abraham returning from the slaughter of the kings and blessed him;' 'The LORD has sworn and will not change his mind, "You are a priest for ever after the order of Melchizedek."	Because Jesus was not part of the recognized priesthood, a Midrashic attempt was made to link Jesus with another scriptural figure who was not of the regular Jewish priesthood, Melchizedek.
Passion				
Zechariah 9:9-11	'Rejoice greatly, O daughter of Zion! Shout aloud, O daughter of	Matt 21:7-9	And [the disciples] brought the ass, and the colt, and put on them their clothes, and	Misdrashic interpretation of Zechariah's account of the King entering

	Jerusalem! Lo, your king comes to you; triumphant and victorious is he, humble and riding on an ass, on a colt the foal of an ass.		they set him thereon....And the multitudes that went before, and that followed, cried, saying Hosanna in the highest. And when he was come into Jerusalem, all the city was moved, saying Who is this? And the multitude said, this is Jesus the prophet of Nazareth of Galilee.	Jerusalem. The story was muted to convey the entry of Jesus in the Holy City.
Zechariah 14:21	'and every pot in Jerusalem and Judah shall be sacred to the LORD of hosts, so that all who sacrifice may come and take of them and boil the flesh of the sacrifice in them. And there shall no longer be a trader in the house of the LORD of hosts on that day.'	Matt 21:12-13	And Jesus went into the temple of God, and cast out all them that sold and bought in the temple, and overthrew the tables of the moneychangers, and the seats of them that sold doves, and said unto them, It is written, My house shall be called the house of prayer; but ye have made it a den of thieves.	Another story from Zechariah that was modified to convey the idea that Jesus had cast out the moneychangers and cleansed the temple.
Judas				
Zechariah 11 :13	Then the LORD said to me, "Throw it to the potter, that magnificent price at which I was valued by them" So I took the thirty shekels of silver and threw them to the potter in the house of the Lord..	Matt. 27 :3-7	'When Judas, his betrayer, saw that he was condemned, he repented and brought back the thirty pieces of silver to the chief priests and the elders, saying, "I have sinned in betraying innocent blood." ... And throwing down the pieces of silver in the temple, he departed; ..And they conferred	Lifting of the story from Zechariah, with acknowledgement, of thirty pieces of silver to be used for the burial plot for the poor.

			together and with the money bought the Potter's Field as a burial place for strangers.	
Psalms 41:9	' Even my bosom friend in whom I trusted, who ate of my bread, has lifted his heel against me.'	John 13 :26	'Jesus answered, "It is he to whom I shall give this morsel when I have dipped it." So when he had dipped the morsel, he gave it to Judas, the son of Simon Iscariot.'	The Midrashic use of the story from Psalm 41 of betrayal during the act of eating.
2 Samuel 20: 9-10	"And Joab said to Amasa, Art thou in health, my brother? And Joab took Amasa by the beard with the right hand to kiss him, But Amasa took no heed to the sword that was in Joab's hand; so he smote him therewith in the fifth rib, and shed out his bowels to the ground,..and he died.	Mark 14 :44, 45	'Now the betrayer had given them a sign, saying, "The one I shall kiss is the man; seize him and lead him away under guard." And when he came, he went up to him at once, and said, "Master!" And he... kissed him.'	The act of giving a kiss to signify an act of betrayal lifted from 2 Samuel is used to further flesh out the story of Judas.

Table 5: Theistic Memetic Mutation Old Testament to New Testament (Spong 1996)

In another remarkable theistic memetic mutation, Matthew wishes to anchor the story of Jesus' divine birth in midrash. He chose a passage from a Greek translation of Isaiah 7:14: "Behold a virgin shall conceive and shall bring forth a son and you shall call his name Emmanuel, which means 'God is with us.'" Matthew did not realize or chose to ignore that the word *virgin* had been mistranslated from the original Hebrew text. Properly translated the Isaiah verse reads, "Behold a young woman shall conceive and shall bring forth a son and you shall call his name Emmanuel, which means 'God is with us.'" Thus, the virgin birth story, like the story of Joseph as father, was the creation of a mutated theistic meme. Other examples of extensive midrashic alteration of texts are found in the depiction of the crucifixion, the story of Judas, and the Passion (Table 5).

In a study of the chronological relationships and textual criticisms of early Christian religious texts, Ehrman (1993) has revealed interrelationships and internal corruptions that demonstrate a remarkable selection process leading toward a uniform and non-contradictory religious canon. The confusion created with Jesus' virgin birth and the question of the nature and timing of his divinity led to the development of a number of mutant theistic memes. All Christians believed

that Christ was the Son of God. But what did this mean? New "Christians" wondered, "Was he born God or did he become God at his baptism or did he become God at his crucifixion and death?" Some early Christians believed that Christ was born a man then was "adopted" by God at the time of his baptism and became divine.

Anti-adoptionist theistic mutations by scribes wishing to embrace the orthodox position focused on several key issues in Jesus' life and ministry. The anti-adoptionists wished to support the belief of a divinely inspired virgin birth and to minimize any suggestion that Jesus had a real father (Table 6). In nearly every theistic meme originally written to convey that Joseph was Jesus' father, the text was mutated to enforce the emerging orthodox position that Christ was the Son of God and born of a virgin.

Passage	Change from	Change to	Significance
Anti-Adoptionist			
Luke 2:33, 48 Luke 2:43 Luke 2:48	"father and mother began to marvel" "his parents" "Look your father and I have been grieved, searching for you."	" <i>Joseph</i> and his mother began to marvel." " <i>Joseph and his mother</i> " " <i>Your relatives</i> and I have been grieved, searching"	Jesus the unique Son of God. Orthodox affirmation of the Virgin Birth and that Joseph was in fact not Jesus' father.
Luke 3:22,/ Mark 1:11	"You are my Son, today I have begotten you"	"You are my <i>beloved</i> Son, <i>in you I am well pleased.</i> "	Orthodox opposition to an adopted Jesus. Supports the view that Jesus was the Son of God at birth.
Mark 1:1	." "The beginning of the Gospel of Jesus Christ."	"The beginning of the Gospel of Jesus Christ, <i>the Son of God</i>	Added corruption that supports the orthodox view that Jesus was the Son of God at birth.
Anti-Separationist			
Mark 1:11/Luke 3:22/Matthew 3:16	" the spirit as a dove descending unto him"	"the spirit as a dove <i>upon</i> him"	Jesus, the Christ at His baptism. Divinity of Jesus at his baptism.
Mark 15:34	"My God, my God, why have you forsaken me?"	" My God, my God why have you <i>reviled</i> me."	Jesus not left behind as the crucified Christ is resurrected. Text harmonized with Psalm 22.
Hebrews 2:9	"that he apart from God should taste death for every man"	"that he <i>by the grace of God</i> should taste death for every man."	An orthodox corruption to obscure an interpretation that Christ did not die on the cross
Anti-Docetic			
Luke 22:19-20	"And taking bread,	"And taking bread,	Orthodox interpolation that

	giving thanks, he broke it and gave it to them saying, This is my body. But behold, the hand of the one who betrays me is with me on the table"	giving thanks, he broke it and gave it to theme saying, This is my body <i>that is given for you. Do this in my remembrance. And likewise after supper, saying, this cup is the new covenant in my blood that is poured out for you.</i> But behold, the hand of the one who betrays me is with me on the table"	Christ died for atonement of sins and that real blood was shed for the sins of the world to affirm the reality of his body at the time of the crucifixion.
Luke 22:43-44	Saying, Father, if thou be willing, remove this cup from me: nevertheless not my will, but thine, be done. And when he rose up from prayer, and was come to his disciples, he found them sleeping for sorrow.	Saying, Father, if thou be willing, remove this cup from me: nevertheless not my will, but thine, be done. <i>And there appeared an angel unto him from heaven, strengthening him. And being in an agony he prayed more earnestly: and his sweat was as it were great drops of blood falling down to the ground.</i> And when he rose up from prayer, and was come to his disciples, he found them sleeping for sorrow.	Orthodox interpolation that counters the docetic belief that Christ could not suffer and was not a human of true flesh and blood.
Luke 24: 111-12	"And their words seemed to them as idle tales, and they believed them not"	"And their words seemed to them as idle tales, and they believed them not. <i>Then arose Peter, and ran unto the sepulchre; and stooping down, he beheld the linen clothes laid by themselves, and departed, wondering in himself at the which was to come to pass.</i> "	Orthodox interpolation that Christ's literal body had been raised from the dead and this was recognized by the chief disciple and was not a silly tale by hysterical women.

Table 6: Theistic Memetic Mutations in Early Christian Canon (Ehrman 1993)

Marcion of Pontus (second century CE) was the son of an orthodox bishop of the church of Sinope. After disagreements with his father about church doctrine, he was forced to leave the

church. He eventually became a wealthy ship owner and once again tried to influence the church. This time he went to Rome and, after making a large donation to the Church, attempted to establish a dominant Christian canon. Marcion seized upon the writings of Paul as a rejection of Jewish Law and scripture, and he proposed a canon consisting of Pauline letters with Luke's gospel, purged of Hebrew scriptural references. So complete was the rejection of the Jewish God that Marcion believed Christ was not descended from the Old Testament creator god but was sent by a "stranger" god. Since Christ was not of the Creator God, he could not have been born and thus could not have been a flesh-and-blood human being. Marcion's views thus expressed the basic tenets of *Gnosticism*. When presented to a council of the Church of Rome, his work was squarely rejected and his donation was returned; he was again excommunicated. Undaunted, Marcion traveled through Asia Minor, where his message and canon were well received. His movement was so successful throughout the Mediterranean region that the Church was provoked to combat the perceived heresy. In reaction to Marcion's teachings and "canon," the Church of Rome convened councils to formulate an "orthodox" canon. The formulation of this canon again involved a conscious "corruption" or mutation of theistic memes in accepted religious texts: the Gospels (Mark, Matthew, Luke, John), Acts, and the Letters of Paul. These mutations countered other interpretations, both anti-adoptionist and Gnostic, from rival churches.

Gnostics believed that Jesus the man and Christ the divine were not the same. Two basic arguments defined Gnosticism. The *Docetics* believed Christ was always divine and only assumed the semblance of a man while on earth. To counter the Docetics, orthodox scribes inserted passages in the early canon that made Jesus appear as a man of real flesh and blood (Table 6). The *Separationists*, the Gnostic majority, believed the divine Christ descended from heaven to inhabit the human being called Jesus at his baptism and gave the saving knowledge (gnosis) during Jesus' ministry; being only a temporal inhabitant, the divine Christ left Jesus' body at the crucifixion. To counter this perceived heresy, orthodox scribes mutated text that suggested Jesus and Christ were separate before his baptism or before his death on the cross (Table 6). These variants were selected and eventually would prevail, establishing the orthodox view. Each variant interpretation had profound effects on the final canon. The Christ embodied in orthodox canon was born divine of a virgin birth; he was both God and a man during his ministry; and after crucifixion his body was resurrected.

6 Theistic Memetic Mutation in Creation of the Islamic Canon

The basic Islamic theistic memes are present in the Qur'an, as given by the Prophet Muhammad in a series of revelations by God over a period of ten years (622-632 ce). Like Jesus, Muhammad was reinterpreting the Jewish Torah and its laws (theistic memes) for his people. But unlike Christ, Muhammad was not a Jew. Although Muhammad knew and respected the "People of the Book," he formulated for the Arabs a monotheistic religion with altered Jewish theistic memes. He claimed the god of the Jews for his religion and Abraham as the first true believer. Any theistic memes attributed to other prophets (including Moses and Christ) that Muhammad did not like were deemed false and discarded. The revelations to Muhammad were eventually transcribed as written theistic memes in the Qur'an - the indisputable and authoritative source for all future followers.

The five structural theistic memes essential to the faith of Muslims are (a) the *shahada*, a public profession of faith: "There is no god but Allah and Muhammad is the Messenger of God"; (b) the *salat*, the performance of a ritual prayer; (c) the *zakat*, obligatory alms; (d) *sawm*, fasting during the month of Ramadan; and (e) the *Hajj*, a pilgrimage to Mecca. These obligatory behaviors are the Pillars of Islam. The Qur'an is the undisputed word of God, and all believers are referred to this source for any questions about appropriate rituals and behaviors. If the memes in the Qur'an are silent or ambiguous on a particular topic, the memes in the *hadiths*, the sayings or reported sayings of Muhammad (collected in the *Sunna*), are consulted. If the *hadiths* are contradictory, the memetic laws of Islamic jurists (the *ijma*) are used to produce uniform behavior. Examples of the Prophet's sayings in the *hadiths* include

Every Muslim has six obligations toward his fellow Muslim: he greets him whenever they meet; answers his call; wishes him well when he sneezes; visits him when he is ill; follow in his funeral when he dies; and wishes for him what he wishes for himself.

The strong man is not the one who knocks people down; the truly strong man is the one who can control himself in anger.

God has no mercy for those who have no mercy for their fellow men.

These Islamic theistic memes, directly related to those of the Old Testament, prescribe how individuals should treat each other. They are in effect Islam's Golden Rules of behavior. In contrast to what we know about the Old and New Testaments, our knowledge about the canonization of the word of God according to Muhammad is remarkably complete. God reportedly revealed his words directly to Muhammad. The verses and phrases were recorded on separate pieces of bone and parchment and, at Muhammad's death (610 ce), three successive caliphs gathered, compiled, and authenticated the text. The Caliph Uthman (644-656 ce) proclaimed an official version of the Qur'an, and all others were deemed false and ordered destroyed. This contrasts with Hebrew and Christian authors spending centuries composing and editing their theistic memes. For the Qur'an, no period was allowed for harmonization of the text. Because only one edition was allowed, tampering with the text was impossible. Thus the Qur'an was "orthodox" from its beginnings; there is no evidence of processes to "corrupt" or mutate the text. However, because the Qur'an was compiled from the unedited recorded sayings of the Prophet and in a relatively short period by one author, inconsistencies would be expected and indeed are present. The most conspicuous inconsistency is the reference to other deities -in conflict with the monotheism so prominently expounded upon later in the text. These deities, al-Lat, al-'Uzza, and Manat, were goddesses present in contemporary religious culture. Because no alteration of the text has been allowed, this glaring inconsistency remains in the Qur'an, creating an unharmonized set of theistic memes.

Perhaps those who constructed the Islamic canon, who must have witnessed the difficulties encountered in formation of the Christian canon, ensured that no such tampering could occur with the Qur'an.

7 Discussion

Religious ideas, concepts, and dictated behaviors, referred to here as theistic memes, have a historical context in the written record beginning about five thousand years ago. Memes have been proposed to vary and undergo selection. The examples provided in this paper show that theistic memes, studied chronologically, have been transmitted from generation to generation (vertical transmission), have varied, and with time have been selected and incorporated into a number of different religious texts. The proposed underlying mechanism for the successful incorporation of a selected theistic meme and its successful propagation in a religious canon is the ability of that meme to enhance human fitness.

A study of the evolution of the *Epic of Gilgamesh* shows how fitness-enhancing memes were progressively incorporated into the canon. In the Sumerian tales, creative scribes infused mutant theistic memes into fanciful stories with little message. The author(s) of the *Epic* took a story that primarily focused on the hero-god himself and transformed the focus into a message about death and the afterlife. They created the first-known recorded theistic memes that directly affected reproductive success by promoting marriage and family ("Pay heed to a little one that holds your hand. / Let a spouse delight in your bosom") and reducing death anxiety (life should be lived for the moment, not in obsessive thoughts of death and the afterlife).

If theistic memes randomly varied, some would, by chance, be fitness minimizing; incorporated into a canon and taken as rules for behavior, these could lead to extinction of a population. The American Shakers are a most notable example of this phenomenon. This Christian sect adopted the fitness-minimizing theistic meme of celibacy. The sect was otherwise not unlike the Quakers of that era, who believed in religious equality of the sexes, a pending apocalypse, and condemnation of established religious hierarchies. Shakers migrated to America in the nineteenth century, and one of these immigrants, Ann Lee, organized the sect into a group of interrelated churches throughout New England. In response to attacks on the religion by the press, the sect adopted a written code of uniform behavior, the Millennial Laws (Shakers 1848), which formalized beliefs and practices for its members and helped define the religion for the general public. The distinctive behavior codified in these Laws was celibacy and separation of the sexes. In Chapter II, the "Principles of the Church of Christ, as revealed to practice in the United Society" list the seven moral duties of the Believer: ". Duty to God 2. Duty to man 3. Separation from the world 4. Practical peace 5. Simplicity of language 6. Right use of property 7. A virgin life." Paragraph 48 of the seventh moral duty reads,

A virgin life, therefore, means a life of purity, a life undefiled with sinful indulgences, unmixed practices, unadulterated with carnal gratifications and impure desires and pursuits. But the sense to which we immediately confine it, and indeed which is the most obvious, is to express a life of continency, or a life of abstinence from carnal gratifications of the flesh, from sexual coition, and from all lascivious indulgences.

In paragraph 51, the Shakers use arguments from the past to justify the virgin life; for example: "Josephus informs us that the Essenes, who maintained the virtue of continence, were many of them favored by divine revelation." Thus the Shaker restriction on marriage and sexual behavior may have had its origins in a historical meme about the Essenes, a sect that also became extinct.

The practicalities of this theistic meme meant that to gain new members the Shakers had to rely on adoptions and conversions. The number of Shaker societies grew in the early eighteenth century, but by the time of the Civil War the number of "Believers" began to decline. With fewer members, inadequate management of Shaker assets and land ensued and contributed to the economic decay of the church. Between 1880 and 1900 the Shaker population declined by half. Burns and colleagues (1996) report a newspaper account of 1905 that described the root of the Shaker demise:

It was a case of love at first sight on both sides when they met four years ago, but neither dared to speak to each other . . . One day, as Audette was passing his lover's window, a thimble dropped to the ground. Looking up he saw Miss Thayer in the window. He immediately tore a piece of paper from a notebook, wrote a proposal of marriage, tucked it in the thimble, and tossed it to his sweetheart. Last November Miss T. forsook the Shaker religion and went to Winsted, Ct . . . where they were married in April.

By the mid-twentieth century the membership had dwindled to forty. Soon thereafter the last male member died. The Shakers, unable to sustain their population, became extinct. The search for the origins of *Homo sapiens* has led to two extremes of beliefs. Either the human species had a divine origin or, like any other species, it evolved from previous life forms. Although there are those who believe strictly in one position or the other, many have adopted a hybrid position in an attempt to reconcile scientific facts with a belief in divine human creation. The most notable of the latter was Alfred Russell Wallace, co-discoverer with Charles Darwin of the theory of evolution by natural selection. Wallace believed that all species evolved according to the Darwin-Wallace theory, except the human species. But as the accumulating scientific evidence provided overwhelming validation of the theory, exclusion of humans from a history of evolution by natural selection became untenable. However, large communities still hold to religious beliefs denying human evolution.

In the scientific community, the present-day debate has polarized into those who categorically deny any divine existence or intervention in life's evolutionary origins and those who believe in human evolution but allow the coexistence and credibility of a formalized religious belief. According to the former group, best represented by Richard Dawkins (1976), all life forms and their respective behaviors have been made possible by evolution through the natural selection of genes over the earth's four billion year history. The latter group, best represented by Stephen Jay Gould, acknowledges the fact of evolution but does not concede that religion is irrelevant. Gould (1987) writes, "Unless at least half my colleagues are inconsistent dunces, there can be -on the most raw and direct empirical grounds -no conflict between science and religion. I know hundreds of scientists who share a conviction about the fact of evolution, and teach it in the same way. Among these people I note an entire spectrum of religious attitudes."

Dennett (1996), in reflecting on this passage, concludes that some evolutionary biologists have in effect drawn a *cordon sanitaire* around the topic of religion and evolution. In this paper I have proposed that *religion is a part of human evolutionary history*.

Another polarizing issue for evolutionary biologists is the question of the extent to which genes influence human behavior. Dawkins (1976) and Wilson (1989) presume that genes play a major

role; Gould (1977) and Dobzhansky (1963) minimize genetic influence on human behavior. Dobzhansky (1963) states,

The first, basic fundamental fact about human evolution is that mankind is simultaneously engaged in two kinds of evolutionary development -the biological and the cultural. Human evolution can be understood only as a product of interaction of these two developments . . . Culture is not inherited through genes, it is acquired by learning from other human beings. In a sense, human genes have surrendered their primacy in human evolution to an entirely new, non-biological or superorganic agent, culture. However, it should not be forgotten that this agent is entirely dependent on the human genotype.

The classic argument used to define the debate between these two groups, as proposed by Gould (1977), is the self-sacrificing behavior of Eskimos. In some family groups of Eskimos, when food becomes scarce, older family members willingly sacrifice themselves to enhance the survivability of their children and grandchildren. The gene theorists believe this altruistic trait is under direct genetic control. Families with the gene for altruism, whose grandparents increased the survivability of younger generations by sacrificing themselves in times of hardship, have increased fitness. Those lacking the gene are less fit and will likely perish.

That such a complex social strategy could be under genetic control -implying that translation of DNA into a specific protein leads directly to a behavior specific to a particular population -seems implausible. Although genetic influence in certain human behaviors is incontrovertible (Steen 1996), genetic control of all social behaviors and strategies would seem far beyond the functional capability of the genetic code. But if genes do not directly control social behavioral strategies, what does?

Gould's answer, using the scenario of altruism among Eskimos, is that the behavior is an adaptive, nongenetic cultural trait. Some families celebrate sacrifice in song or story, venerating aged grandparents who sacrificed themselves and thus maintaining the capacity for this fitness-enhancing behavior through family generations. Families without such a tradition, passed through stories or legends, could become extinct.

This proposed role of religion in human evolution is in agreement with Benedict's (1989) assumption that the human species has a range of genetically determined behaviors, evolved through natural selection. Within this range of plastic social strategies and behaviors, specific strategies and behaviors are executed not under genetic control but under some sort of societal influence or religious mandate. Religious laws are subject to selection and can evolve to provide the species with greater fitness and reproductive success. The agent affecting fitness is the meme, as conceived by Dawkins: a unit of cultural transmission, propagated from generation to generation as the spoken or written word. Memes resemble genes in that they carry information, can randomly vary, and are subject to selection. Most importantly, they can affect human survivability and fitness. The culturally transmitted songs or stories of which Gould speaks in his explanation of self-sacrifice in Eskimos, and which Dobzhansky calls "new, nonbiological or superorganic agent[s]," are in fact memes.

The model proposed in this paper takes the meme concept further: in some populations, memes have been selected to produce a religious literature that enhances the population's fitness by providing strict codes of conduct and social strategies. The phenotypic expression of behavior is determined first by a broad spectrum of possibilities provided by a genotype; but the specific behavior executed is determined by a theistic meme incorporated in a religious canon.

This model stipulates that religion evolved as a consequence of humans' sophisticated self-awareness. The model recognizes the important contribution of Maser and Gallup (1990) in describing humans' self-awareness as a trait that enhances fitness but also creates the epiphenomenon of an awareness of finiteness and eventual death. At some point in human evolutionary history, self-awareness created a void in humans' interpretation and understanding of their world. At that juncture, the species needed answers to alleviate fears and anxieties arising from awareness of the unknown and death. The god concept filled this void. With the advent of writing some 6000 years ago, the specifics of god and the relationship between humans and god began to take on a permanent, indelible form. These written forms could have three different effects on the fitness of the gene pool: positive, negative, or neutral (no effect). What has been demonstrated here to support this model is that theistic literature has been subject to selection. Fitness-enhancing theistic literature has survived to become canon; fitness-minimizing theistic literature has not survived selection and has become extinct.

The model described here is supported by the unique and remarkable fitness provided by theistic memes in the Jewish canon for several millennia (Table 7). The Hebrew religious canon underwent profound evolutionary changes, providing increasing fitness at four distinct periods in its history. In the formative period, after the Exile (around 1300 bce), the Covenant code and the Decalogue provided the Hebrews with a unique understanding of the relationship with God: all men were equal under a covenant made with a just God. The later Deuteronomic code affirmed this relationship, excluding foreign religious influences and incorporating fitness-enhancing memes about sexual behavior that promoted the nuclear family. Of profound importance in limiting Hebrew fitness, however, was the practice of child sacrifice. Addition to the canon of a strict prohibition of this practice (including the story of Abraham and Isaac), with sacrifice transferred to animals, markedly raised overall fitness. The Holiness code further affected reproductive fitness by severely limiting behaviors such as prostitution, incest, adultery, sodomy, and bestiality and encouraging fitness-enhancing behaviors that perpetuated the nuclear family.

Table 7: Theistic Memetic Types and Fitness Index in Various Religious Canon

Most of the Torah is related to outlining a credible world order: the nature of God, God's credibility, God's relationship to man, and the behaviors necessary to obtain holiness. The great majority of the 613 commandments in the Torah are devoted to these topics. However, in the long and tumultuous history of the Hebrews, the Law had to be modified (mutated) to fit the times. The remarkable stability of the Jewish canon that emerged from the multitude of ancient Near Eastern populations is due to the incorporation of fitness-maximizing theistic memes and the rejection of fitness-minimizing memes. However, the Hebrew population, in its highly stable state of fitness, was confined by laws against intermarriage. Other reproductive populations with less stable fitness were, by self-awareness, at a disadvantage.

The Christian canon enabled gentiles and disaffected Jews to rise to the same level of fitness as the Jewish population (Table 7). The Christian canon, accepted by many populations, was able to overwhelm less stable fitness strategies throughout the Roman Empire. For Arabic populations living with a polytheistic canon, Muhammad created an Arabic Jewish monotheism, incorporating in the Qur'an essentially the same fitness-maximizing theistic memes found in the Hebrew Torah. Through human history, some populations have assumed mutant theistic memes that were detrimental to fitness. The Shakers are a vivid example of a religious population that incorporated the lethal theistic memetic mutation of celibacy.

MEMES: INTRODUCTION

By

Glenn Grant, Memeticist

*"An idea is something you have;
an ideology is something that has you."
--Morris Berman*

What if ideas were viruses?

Consider the T-phage virus. A T-phage cannot replicate itself; it reproduces by hijacking the DNA of a bacterium, forcing its host to make millions of copies of the phage. Similarly, an idea can parasitically infect your mind and alter your behavior, causing you to want to tell your friends about the idea, thus exposing them to the idea-virus. Any idea which does this is called a "meme" (pronounced `meem').

Unlike a virus, which is encoded in DNA molecules, a meme is nothing more than a pattern of information, one that happens to have evolved a form which induces people to repeat that pattern. Typical memes include individual slogans, ideas, catch-phrases, melodies, icons, inventions, and fashions. It may sound a bit sinister, this idea that people are hosts for mind-altering strings of symbols, but in fact this is what human culture is all about.

As a species, we have co-evolved with our memes. Imagine a group of early *Homo sapiens* in the Late Pleistocene epoch. They've recently arrived with the latest high-tech hand axes and are trying to show their *Homo erectus* neighbours how to make them. Those who can't get their heads around the new meme will be at a disadvantage and will be out-evolved by their smarter cousins.

Meanwhile, the memes themselves are evolving, just as in the game of "Telephone" (where a message is whispered from person to person, being slightly mis-replicated each time). Selection favors the memes which are easiest to understand, to remember, and to communicate to others. Garbled versions of a useful meme would presumably be selected out.

So, in theory at least, the ability to understand and communicate complex memes is a survival trait, and natural selection should favor those who aren't too conservative to understand new memes. Or does it? In practice, some people are going to be all too ready to commit any new meme that comes along, even if it should turn out to be deadly nonsense, like:

"Jump off a cliff and the gods will make you fly."

Such memes do evolve, generated by crazy people, or through mis-replication. Notice, though, that this meme might have a lot of appeal. The idea of magical flight is so tantalizing -- maybe, if I truly believed, I just might leap off the cliff and...

This is a vital point: people try to infect each other with those memes which they find most appealing, regardless of the memes' objective value or truth. Further, the carrier of the cliff-

jumping meme might never actually take the plunge; they may spend the rest of their long lives infecting other people with the meme, inducing millions of gullible fools to leap to their deaths. Historically, this sort of thing is happening all the time.

Whether memes can be considered true "life forms" or not is a topic of some debate, but this is irrelevant: they behave in a way similar to life forms, allowing us to combine the analytical techniques of epidemiology, evolutionary science, immunology, linguistics, and semiotics, into an effective system known as "memetics." Rather than debate the inherent "truth" or lack of "truth" of an idea, memetics is largely concerned with how that idea gets itself replicated.

Memetics is vital to the understanding of cults, ideologies, and marketing campaigns of all kinds, and it can help to provide immunity from dangerous information-contagions. You should be aware, for instance, that you just been exposed to the Meta-meme, the meme about memes... The lexicon which follows is intended to provide a language for the analysis of memes, meme-complexes, and the social movements they spawn. The name of the person who first coined and defined each word appears in parentheses, although some definitions have been paraphrased and altered.

MEMETIC LEXICON

By

Glenn Grant

PO Box 36 Station H, Montreal, Quebec, H3C 2K5 (1990)

Auto-toxic

Dangerous to itself. Highly auto-toxic memes are usually self-limiting because they promote the destruction of their hosts (such as the Jim Jones meme; any military indoctrination meme-complex; any "martyrdom" meme). (GMG) (See exo-toxic.)

bait

The part of a meme-complex that promises to benefit the host (usually in return for replicating the complex). The bait usually justifies, but does not explicitly urge, the replication of a meme-complex. (Donald Goings, quoted by Hofstadter.) Also called the reward co-meme. (In many religions, "Salvation" is the bait, or promised reward; "Spread the Word" is the hook. Other common bait co-memes are "Eternal Bliss", "Security", "Prosperity", "Freedom".) (See hook; threat; infection strategy.)

belief-space

Since a person can only be infected with and transmit a finite number of memes, there is a limit to their belief space (Henson). Memes evolve in competition for niches in the belief-space of individuals and societies.

ensorship

Any attempt to hinder the spread of a meme by eliminating its vectors. Hence, censorship is analogous to attempts to halt diseases by spraying insecticides. Censorship can never fully kill off an offensive meme, and may actually help to promote the meme's most virulent strain, while killing off milder forms.

co-meme

A meme which has symbiotically co-evolved with other memes, to form a mutually-assisting meme-complex. Also called a symmeme. (GMG)

cult

A sociotype of an auto-toxic meme-complex, composed of membots and/or memeoids. (GMG) Characteristics of cults include: self-isolation of the infected group (or at least new recruits); brainwashing by repetitive exposure (inducing dependent mental states); genetic functions discouraged (through celibacy, sterilization, devalued family) in favor of replication (proselytizing); and leader-worship ("personality cult"). (Henson.)

dormant

Currently without human hosts. The ancient Egyptian hieroglyph system and the Gnostic Gospels are examples of "dead" schemes which lay dormant for millennia in hidden or untranslatable texts, waiting to re-activate themselves by infecting modern archeologists. Some

obsolete memes never become entirely dormant, such as Phlogiston theory, which simply mutated from a "belief" into a "quaint historical footnote."

earworm

"A tune or melody which infects a population rapidly." (Rheingold); a hit song. (Such as: "Don't Worry, Be Happy".) (f. German, *ohrwurm*=earworm.)

exo-toxic

Dangerous to others. Highly exo-toxic memes promote the destruction of persons other than their hosts, particularly those who are carriers of rival memes. (Such as: Nazism, the Inquisition, Pol Pot.) (See meme-allergy.) (GMG)

hook

The part of a meme-complex that urges replication. The hook is often most effective when it is not an explicit statement, but a logical consequence of the meme's content. (Hofstadter) (See bait, threat.)

host

A person who has been successfully infected by a meme. See infection, membot, memeoid.

ideosphere

The realm of memetic evolution, as the biosphere is the realm of biological evolution. The entire memetic ecology. (Hofstadter.) The health of an ideosphere can be measured by its memetic diversity.

immuno-depressant

Anything that tends to reduce a person's memetic immunity. Common immuno-depressants are: travel, disorientation, physical and emotional exhaustion, insecurity, emotional shock, loss of home or loved ones, future shock, culture shock, isolation stress, unfamiliar social situations, certain drugs, loneliness, alienation, paranoia, repeated exposure, respect for Authority, escapism, and hypnosis (suspension of critical judgment). Recruiters for cults often target airports and bus terminals because travelers are likely to be subject to a number of these immuno-depressants. (GMG) (See cult.)

immuno-meme

See vaccine. (GMG)

infection

1. Successful encoding of a meme in the memory of a human being. A memetic infection can be either active or inactive. It is inactive if the host does not feel inclined to transmit the meme to other people. An active infection causes the host to want to infect others. Fanatically active hosts are often membots or memeoids. A person who is exposed to a meme but who does not remember it (consciously or otherwise) is not infected. (A host can indeed be unconsciously infected, and even transmit a meme without conscious awareness of the fact. Many societal norms are transmitted this way.) (GMG)

2. Some memeticists have used 'infection' as a synonym for 'belief' (i.e. only believers are infected, non-believers are not). However, this usage ignores the fact that people often transmit memes they do not "believe in." Songs, jokes, and fantasies are memes which do not rely on "belief" as an infection strategy.

infection strategy

Any memetic strategy which encourages infection of a host. Jokes encourage infection by being humorous, tunes by evoking various emotions, slogans and catch-phrases by being terse and continuously repeated. Common infection strategies are "Villain vs. victim", "Fear of Death", and "Sense of Community". In a meme-complex, the bait co-meme is often central to the infection strategy. (See replication strategy; mimicry.) (GMG)

membot

A person whose entire life has become subordinated to the propagation of a meme, robotically and at any opportunity. (Such as many Jehovah's Witnesses, Krishnas, and Scientologists.) Due to internal competition, the most vocal and extreme membots tend to rise to top of their sociotype hierarchy. A self-destructive membobot is a memeoid. (GMG)

meme

(pron. 'meem') A contagious information pattern that replicates by parasitically infecting human minds and altering their behavior, causing them to propagate the pattern. (Term coined by Dawkins, by analogy with "gene".) Individual slogans, catch-phrases, melodies, icons, inventions, and fashions are typical memes. An idea or information pattern is not a meme until it causes someone to replicate it, to repeat it to someone else. All transmitted knowledge is memetic. (Wheelis, quoted in Hofstadter.) (See meme-complex).

meme-allergy

A form of intolerance; a condition which causes a person to react in an unusually extreme manner when exposed to a specific semiotic stimulus, or 'meme-allergen.' Exo-toxic meme-complexes typically confer dangerous meme-allergies on their hosts. Often, the actual meme-allergens need not be present, but merely perceived to be present, to trigger a reaction. Common meme-allergies include homophobia, paranoid anti-Communism, and porno phobia. Common forms of meme-allergic reaction are censorship, vandalism, belligerent verbal abuse, and physical violence. (GMG)

meme-complex

A set of mutually-assisting memes which have co-evolved a symbiotic relationship. Religious and political dogmas, social movements, artistic styles, traditions and customs, chain letters, paradigms, languages, etc. are meme-complexes. Also called an m-plex, or scheme (Hofstadter). Types of co-memes commonly found in a scheme are called the: bait; hook; threat; and vaccine. A successful scheme commonly has certain attributes: wide scope (a paradigm that explains much); opportunity for the carriers to participate and contribute; conviction of its self-evident truth (carries Authority); offers order and a sense of place, helping to stave off the dread of meaninglessness. (Wheelis, quoted by Hofstadter.)

memeoid, or memoid

A person "whose behavior is so strongly influenced by a [meme] that their own survival becomes inconsequential in their own minds." (Henson) (Such as: Kamikazes, Shiite terrorists, Jim Jones followers, any military personnel). hosts and membots are not necessarily memeoids. (See auto-toxic; exo-toxic.)

meme pool

The full diversity of memes accessible to a culture or individual. Learning languages and traveling are methods of expanding one's meme pool.

memetic

Related to memes.

memetic drift

Accumulated mis-replications; (the rate of) memetic mutation or evolution. Written texts tend to slow the memetic drift of dogmas (Henson).

memetic engineer

One who consciously devises memes, through meme-splicing and memetic synthesis, with the intent of altering the behavior of others. Writers of manifestos and of commercials are typical memetic engineers. (GMG)

memeticist

1. One who studies memetics. 2. A memetic engineer. (GMG)

memetics

The study of memes and their social effects.

memotype

1. The actual information-content of a meme, as distinct from its sociotype.
2. A class of similar memes. (GMG)

meta-meme

Any meme about memes (such as: "tolerance", "metaphor").

Meta-meme, the

The concept of memes, considered as a meme itself.

Millennial meme, the

Any of several currently-epidemic memes which predict catastrophic events for the year 2000, including the battle of Armageddon, the Rapture, the thousand-year reign of Jesus, etc. The "Imminent New Age" meme is simply a pan-denominational version of this. (Also called the 'Endmeme'.)

mimicry

An infection strategy in which a meme attempts to imitate the semiotics of another successful meme. Such as: pseudo-science (Creationism, UFOlogy); pseudo-rebelliousness (Heavy Metal); subversion by forgery (Situationist detournement). (GMG)

replication strategy

Any memetic strategy used by a meme to encourage its host to repeat the meme to other people. The hook co-meme of a meme-complex. (GMG)

retromeme

A meme which attempts to splice itself into an existing meme-complex (example: Marxist-Leninists trying to co-opt other sociotypes). (GMG)

scheme

A meme-complex. (Hofstadter.)

sociotype

1. The social expression of a memotype, as the body of an organism is the physical expression (phenotype) of the gene (genotype). Hence, the Protestant Church is one sociotype of the Bible's memotype. 2. A class of similar social organisations. (GMG)

threat

The part of a meme-complex that encourages adherence and discourages mis-replication. ("Damnation to Hell" is the threat co-meme in many religious schemes.) (See: bait, hook, vaccime.) (Hofstadter)

Tolerance

A meta-meme which confers resistance to a wide variety of memes (and their sociotypes), without conferring meme-allergies. In its purest form, Tolerance allows its host to be repeatedly exposed to rival memes, even intolerant rivals, without active infection or meme-allergic reaction. Tolerance is a central co-meme in a wide variety of schemes, particularly "liberalism", and "democracy". Without it, a scheme will often become exo-toxic and confer meme-allergies on its hosts. Since schemes compete for finite belief-space, tolerance is not necessarily a virtue, but it has co-evolved in the ideosphere in much the same way as co-operation has evolved in biological ecosystems. (Henson.)

vaccime

(pron. vak-seem) Any meta-meme which confers resistance or immunity to one or more memes, allowing that person to be exposed without acquiring an active infection. Also called an 'immuno-meme.' Common immune-conferring memes are "Faith", "Loyalty", "Skepticism", and "tolerance". (See: meme-allergy.) (GMG.)

Every scheme includes a vaccime to protect against rival memes. For instance:

Conservatism: automatically resist all new memes.

Orthodoxy: automatically reject all new memes.

Science: test new memes for theoretical consistency and (where applicable) empirical repeatability; continually re-assess old memes; accept schemes only conditionally, pending future re:-assessment.

Radicalism: embrace one new scheme, reject all others.

Nihilism: reject all schemes, new and old.

New Age: accept all esthetically-appealing memes, new and old, regardless of empirical (or even internal) consistency; reject others. (Note that this one doesn't provide much protection.)

Japanese: adapt (parts of) new schemes to the old ones.

vector

A medium, method, or vehicle for the transmission of memes. Almost any communication medium can be a memetic vector. (GMG)

Villain vs. Victim

An infection strategy common to many meme-complexes, placing the potential host in the role of Victim and playing on their insecurity, as in: "the bourgeoisie is oppressing the proletariat" (Hofstadter). Often dangerously toxic to host and society in general. Also known as the "Us-and-Them" strategy.

MEMES AND THE CREATION OF NEW PATTERNS OF MOVEMENT IN DANCE

By

Prof. Dr. Christine Greiner

Catholic University of São Paulo, Center of Dance Studies of the Department of Semiotics
(PUC-SP)

This paper aims to study the influence of cultural dialogue in the creation of new patterns of movement in dance and to develop a hypothesis to understand how it works, presenting a practical example: the evolution of butoh dance in the West.

Butoh is a radical artistic manifestation born in Japan in the late 50s; after the 80s it spread through the Western world, suffering successive degradations. Besides Pina Bausch's Tanztheatre, butoh thought can be indicated as one of the powerful memes developed in the second half of our century.

However, we have to be careful to avoid hasty conclusions, questioning whether we can really understand butoh as a meme and, if so, we have to clarify what kind of instruction it really offers to the replication process.

We will take as fundamental theoretical instruments: the Consciousness Thesis of Daniel Dennett (1991;1995;1997), the Meme Thesis (1976) of Richard Dawkins and Charles Darwin's (1859) idea of evolution by natural selection, interpreted by Dawkins and Dennett.

Such a methodological choice transfers theoretical and conceptual matrices of the cultural dialogue problem from the outer scope of sciences that have considered aesthetical changes of choreographies as simple products of socio-cultural stimulus of the environment to the understanding of cultural dialogue as an action of consciousness (and not its product). Therefore, perceiving an environment is not to make the brain receive stimuli in a passive way.

According to Dawkins (1982), a meme should be regarded as a unit of information residing in a brain. It has a definite structure, realized in whatever physical medium the brain stores information. This means: as a pattern of synaptic connections or in a distributed form. In the latter, it would not be detectable on a microscope, but, Dawkins insists, it still reside in the brain.

These mental representations and the movements implemented in the body are a necessary integration (brain-body-environment) that affords not only the artistic making, but the survival.

Through cultural dialogue, mental representations (memes) are changed because the brain receives new information through different modes of perception. To understand how this transformation of mental representations influences the creation of new patterns of movement in dance, it is necessary to think about the implementation of this information in the dancing body.

According to Dawkins, a cake is the consequence of obeying a series of instructions when to mix the various ingredients but it is not those instructions translated into another coding medium. A

body too, is the result of obeying instructions, but we cannot reconstruct an individual's genome by studying his body. And the same happens to the dancing body. When you learn a new dance technique and receive the instructions, you will not translate them into another medium, thereby recovering the "original". In the new environment, the instructions will be re-organized according to the brain-body continuum, establishing new relationships, and different mental representations that once implemented in the body, will give birth to new patterns of movement.

Time develops an important role in this process. In the dancing body, to develop a new pattern of movement, it is necessary to conquer a minimum of stability. This stable thought, that Dennett called conscious thought, will permit a dance movement (implemented thought) to exist as a habit, i.e. a movement already incorporated to create a specific dancing body.

According to Dennett (1991:210): "human consciousness is itself best understood as the operation of a 'von Neumannesque' virtual machine implemented in the parallel architecture of a brain that was not designed for any such activities". Dennett (1996:155) explains that mental contents become conscious not by entering some special chamber in the brain but by winning the competition against others.

In dance, memes, as mental representations and the process of replication of these representations of ideas (or other imagined constructs), are phenotypically mediated by the dancing body. In this transit between mental patterns and body implementation, natural selection occurs at different levels. There is a big difference between replicators and vehicles.

The example of butoh evolution

To understand butoh evolution we ask a question to identify this relationship: which is the information of this universe of knowledge that is able to replicate?

As we said before, a vehicle is not a replicator. Therefore, the dead body or even the idea of the dead body (the fundamental of butoh dance) cannot be replicated. Only the instructions that make it happen.

At this point, it is important to review some basic principles to think about their evolution in the West.

Semantics professor Yoshie Yoshida discusses some of the main translations of the butoh ideogram, explaining that in general butoh is understood as the harmony between elevation (*bu*) and being earth bound. However, he interprets *bu* (from *buyo*) as *mai* (another name for dance in Japanese). In this sense, *bu* could mean *ma-i* or the action of *ma* (known as the conception of the time-space interval that is a fundamental aspect of Japanese culture). The choreographer Akaji Maro, who worked for many years with Tatsumi Hijikata, the creator of butoh dance, said that the body is supported by something invisible. Butoh is about capturing the spirits that live in *ma*. It is beyond outside time.

To complete this reasoning, we can already mention another butoh choreographer, Ko Murobushi, who explains the dead body as the possibility of giving existence to anything. Like

ma, which can be understood not as an empty place in the sense of nothingness, but in the sense of emptiness in which anything can happen.

Therefore, we think about *ma* as a kind of instruction of the butoh meme. Or, more specifically, of the dead body meme, as an imaginary construction.

If this instruction is able to replicate in other bodies, it will not reproduce or translate butoh is another medium (a western body, for example). But it will exist as another possibility of experiencing life.

After many years of studying butoh, we have concluded that a good definition for butoh is to think about this dance as a map of one of the possibilities of the state of being alive.

Butoh is just one example. The Memetics approach can contribute to the study of dance by reorganizing Dance History and the understanding of the evolution of the different dances.

It permits to think about what kind of instructions can or cannot replicate, according to the relationship present at the continuum body-brain-environment.

Thinking about the creation of new patterns of movement in dance, based on cultural dialogue, Memetics explains that it is not enough to study the environment, neither the mental representations apart from their extended phenotypes. It is in the transit between mental representation and its implementation in the dancing body, that natural selection is responsible for the aesthetical result. Therefore, cultural dialogue in dance is often responsible for the creation of new patterns of movement in the dancing body, but not by a sociological effect of the external world on the inner world of the dancer, but by natural selection of the competition among mental contents, meme-effects in brains. In this sense, it's the same process that is present in all nature: an algorithmic process (Dennett, 1995, 1996; Dawkins, 1986, 1995, 1996) creating new designs.

**MEMES AND GRINNING IDIOT PRESS
OR
WHY I HAVE BEEN STUDYING VAMPIRES SINCE 1972**

By
Grinning Idiot Press 1993
716 Unit A 21 St N
St Petersburg FL 33713
(813)321-2120

Why GRINNING IDIOT PRESS?

At one time I was involved in a somewhat extreme version of Christianity; I joined in my innocent and ignorant teenage years when I was vulnerable. The group I fell under the sway of is in the outer territory of cultdom; I will not name names. Somewhere along the line I forgot to turn off my bright and inquiring mind, which led to no end of trouble for me. At first I simply wanted to learn all about the faith, but after I learned a thing I thought about it and what it meant and how it related to other things in the faith I was taught.

After discovering that when I criticized certain ideas and doctrines and tried to analyze them logically in debate with respected authorities in the faith, I elicited irrational behavior from them, which surprised me immensely. At the time, I associated with this group, and considered myself one of the good guys, like them. My motive was to dispel apparent contradiction; it never dawned on me (how naive) that there were things thou shalt not question. When I criticized or questioned certain things or pointed out apparent contradictions, the results were amazing and VERY traumatic. I thereafter did my research in private and slowly came to certain conclusions and discoveries which were NOT approved right thinking. I came to the conclusion that they were not very sane, and that a few of them were downright irrational. Further research led me to understand the compartmenting behaviour, where a cultist leads one part of their life by one definition of logic, which is NOT applied to all parts. If I fixed my brakes by this sort of sanity, the ride would be exciting, to say the least. In short, I burned out.

This led to a year long bout of depression and internal conflict as my rational mind came to grips with habitual mental behavior that was difficult to stop. I came to understand that I had to some extent been programmed, and that I had assisted it, if only by default. It took some time to come to trust and like myself after that, and to understand what happened and how. I had been ABSOLUTELY CERTAIN I was right, only to later discover I had been in error. Self trust, and faith in general, became VERY iffy things.

It was easy to ascribe evil intentions to these people, but on examination of several with carefully worded questions and long term observation of their behavior, I satisfied myself that they in fact were as programmed as was I, or more so. This left me wondering how such things come to be, until I read certain works by Robert A. Wilson, Dawkins, and others.

After I had learned and discovered many things, got my facts and head (a little more) straight, and developed a measure of understanding, I engaged in a series of discussion groups and

debates with several members of this community of like minded individuals, some of whom were respected scholars in their system of thought. At this time, my theories were still quite primitive, and I was not very certain about what would happen, which was part of why I did it. The results were remarkable. They displayed an amazing selective blindness to evidences, a fascinating selective memory concerning evidences produced, and utterly defective recall of the evenings in question several months later when I spoke to the organizer at a party. I remain convinced they were being spontaneous and NOT intending to deceive me.

An associate insists they are liars, and dishonest men pursuing an agenda of power. Concerning 90% of them, I disagree. People do not react that quickly when their reactions are not preplanned (as they did not know what to expect), and are deliberately chosen to play a role supporting some ulterior motive. Their emotions do not become so intense when faked as to raise blood pressure (with attendant flushing), produce sweat, fidgeting, and other body english. These people really meant it, however irrational their favored persuasions. They are in effect captives of coherent information systems which have subverted their ability to deliberate, to THINK; they are 'possessed' by what are called MEMES, information viruses. A popular counter culture term for such is robots. Those with limited or total immunity who use them to control robots, and are to some extent aware they are doing it, are termed vampires, a term invented by an author. PSYCHIC vampires, as they drain off free will and enslave minds. I refine such terms in a moment. Cult lords are vampires.

When I spoke to these robots, they seemed to ignore anything I said and spoke and acted as if I was somehow mentally impaired (improperly programmed?), and had to be led to the truth gently by the hand, like some sort of a grinning idiot (a term I heard descriptive of simpletons in my child hood from my friend next door Carl Cleback). Fascinating. Were they truly liars, or fools who really and truly mean it? (Yes, I later found out.)

Investigating further, I came across more of the writings of Robert Anton Wilson which pointed out to me that there is in men a thing Leary calls the reality grid, a system of information whereby we interpret all raw information coming in from the senses as important or trivial; it also helps us determine WHAT the information means. I was on to something. Another work, *The Selfish Gene* by Dawkins introduced an idea and a word, the MEME, a coherent system of information which tends to 'hang together' and propagate through society, existing pretty much for its own sake. Some are harmless, or even beneficial, such as the 'stop, drop, and roll' poem and song invented by the Canadian government. (IN BRIEF, it reminds people whose clothing is on fire to NOT run in panic, but instead, stop, lie down, and roll the fire out. Cool?)

I came to believe that many people are robots controlled by memes. A few are partially or totally immune to their chosen virus, but continue to associate with them and the participating robots for the bennies of prestige, power, money, and sometimes even nookie, these I term vampires. Highly successful ones I call Vampire Lords. The ones who are infected without knowledge of it are the robots. Some admitted the programming but did not know what they were doing. They are still robots. They are not particularly awake. Vampires have some partial awareness of what is up at least; robots do not. They are oblivious, and are controlled by whatever got into their minds. If that data included some defensive software, they will resist further programming by unauthorized sources. The control loop for a robot is externalized with random sources and

programming, or a specific source and program for the `possessed' robot, the lackey of a vampire, a predatory neuromancer. Some of them are very good at it. Jim Jones was one such. Unfortunately, he was not immune to his virus, and succumbed to the self destruct program he created. He would not have been executed; we would have certainly found him insane. Half assed neuromancers are dangerous. To themselves.

People who control the programming of their own minds are called occultists or heretics or neuromancers or free spirits. People whose programs are sourced and defined by outside agents are ROBOTS. People WITHOUT programs in their subconscious minds are totally insane, or dead. People who define other people's programming may be consulting technicians, but if they do it to define that other person to their tastes, particularly to their benefit, they are practicing vampires.

Preprogrammed behavior which preserves life is VERY useful when you are filled with panic and the deliberative mind is running in circles screaming. The meme which allows you to remain standing erect while lost in thought is a complex and carefully structured meme. You invested years of work in developing it. It is a benign, unaggressive, and useful program dwelling now in the subconscious mind. Such skills are very useful. Everything they teach you in boot camp is ideally engraved on your brain stem for when seconds are far too long to take to decide and the wind from the grenades is blowing your sweat soaked hair dry and you're so scared the urine is running down your pant leg -- THAT is why you drill and practice until you DREAM how to field strip a rifle blindfolded. MAYBE your D.I. knew what he was doing?

Others have NOTHING to do with the well being of persons they infect, and are simply self replicating for their own sake. The simplest was invented by Dawkins, and is titled `Say me'. SAY ME! There; I've done it; you are now infected with an information virus, a harmless one. Say me. Granted, it's so simple there is little to no reward for playing the sayme mind game, but there it is, and even so simple a meme has surprising persistence and propagation. Others are indeed seductive, even enjoyable to the mind they are subverting, but are irrational say me and harmful, either to the host, those around the host, or both.

Obviously there are many sorts of religion (and politics) which are unrational systems of self propagating information systems `riding' host humans. Nazi fascism is such a meme, a large and complex one; so is irrational compulsive screaming emotional manipulative socialism, the sort that is sacred and therefore may not be criticized; it is politically incorrect to question it, disagree with it, or question it critically. (There is a conservatism like this too, a feminism, a macho masculine male superiority thing, a white thing, a black thing, an Islamic thing, an Atheistic thing, and so-on; each is equally irrational, and is also a meme; I am sure you can name religious groups like this. They are sometimes thought of as cults, but ALL of them are memes.) These memes invade using pseudo-rational trickery, outright brain washing, punishment for criticism, and anything else that bypasses rational examination, such as mental ignorance or sloth.

Many are subverted simply because they do not know better, such as the uninformed, the naive, cowards who prefer not to perceive than to resist emotional pressure, those who cannot stand the emotional stress of rejection, and children. The politely courageous one who knows that there are no propositions which may not be doubted and examined, who is willing to risk rejection, who

trusts in the process of thought, who knows that ideas have consequences and that words have meanings, such a person is highly resistant to memes -- and very rare. They are declared nonexistent, called every name in the book, and lied about by meme infested persons. The meme victim even believes their own dishonest statements, because they are being enslaved to illusions, and the more so the easier it is to believe one's own lies. Technically, they are insane; they cannot differentiate between reality and unreality, good and evil. As their compartmenting of the mind progresses, actual multiple personality disorder or schizophrenia is quite possible, although few push it this far. Instinct is a powerful counterbalance, and keeps many souls alive mostly on autopilot, while they keep repeating approved programs and mantras. Lest I be received as an arch-Atheist, I also mean programmed robots such as slavish fans of many popular figures, such as Rush Limbaugh, Ayn Rand, Anita Bryant, Jim Jones, Ronald Reagan, and Jane Fonda.

Rational analysis, PAYING ATTENTION, and an unwillingness to accept on a basis of emotional pressure are strong serums say me against these viruses. Say me. Of course, some say me viruses are harmless and even fun SAY ME to play with. Maybe. JUST REMEMBER: If you know you're doing it, you're not schizophrenic.

Some memes are without a doubt destructive, such as those associated with Jim Jones, Herr Hitler, Bulimia, Anorexia, 'BoB', and Alcoholism rooted in psychological disturbances. Almost everyone is to a limited extent controlled by memes not of their deliberate choosing, just as we all carry viruses we are partially resistant to (and some we are not but are benign; they simply get in, reproduce, we spread them, we evict the current crop, they take root elsewhere, and life goes on). There are many types of memes. They exist for their own sake. Usually.

As in organic life vs. viruses, destructive memes which are too toxic destroy their hosts so well they edit themselves out of the informational 'gene pool'. However, if they could be engineered, contained, and released in local areas, such information structures would make excellent weapon systems. I believe this is being inefficiently explored by many parties who only partially understand what they are about. I believe this has been more or less the case for some time. The cult outbreak of the 60's and 70's was simply a particularly toxic and obvious example of memes, in this case memes spread by persons who to some extent knew what they were doing.

Several of these leaders are now in jail or are deceased, yet their memes live on, with the organization attendant being shaken out and purged of corruption; the vampire lord has died, so the robots cleanse the order of the traces of corruption left behind, inventing new memes to explain these puzzling evidences (one of the sacred ideas is that the leader was not in it for the money, ego boost, power, or nookie).

Someday these 'cults' will be old established religions, with long traditions, carefully worked out theologies, and fictitious but very seriously affirmed and believed histories. The meme at such future date will only superficially resemble the one the founder was teaching. If Rabbi Joshua Bar Nazareth were to pop up today in a time warp and go to a church (ANY CHURCH), he would not be approved of; nor would he approve of them. Krishna would be appalled with people talking about him, Siddhartha (the Buddha) would either laugh or cry, at what his people

have made of what he left behind, Bless Me if I know which.

Now, before I get lynched, I do not mean to suggest any of these people were corrupt. Into suffering maybe. No one dead more than 500 years is of anything but the highest order of saintliness or the most vile of evilness, which these were not, unless they are simply no longer recalled at all. These most excellent teachers were simply edited and spin doctored and interpreted to beat hell after they departed. But I digress.

Memes can be useful tools to govern human behavior, yours or mine. They can be harmless, beneficial, or toxic, slightly or greatly. Best of all, they could be disseminated to the target audience with leaflet drops and radio broadcasts on shortwave or AM radio from outside the target audience. And Freedom of Speech protects it. If you think this is nuts and that you cannot talk people to death, please go refresh your memory of Jim Jones' body count. Then visit Auschwitz. When some people shoot their mouths off, they get a body count.

The more I learned, the more I liberated myself, and the more annoying to robots and dangerous to vampires I became. Both tend to shun me like the plague once they begin to know me. I guess they like their viruses more than mine. Perhaps censorship in time of war is simply a sort of public hygiene?

Since then I have been exploring the dynamics of this, keeping track of the performance record of vampires who make public declarations and promises. I also explore how to deprogram the robotic thinking in myself and others, and enable them and myself to replace it with chosen planning which is more enabling, more centered on personal well being and liberation, and more resistant to infection by information viruses by society. This generally pisses off robots and their vampire lords, and authoritarians in general. Free spirits leaning to reading and writing and words (left brain dominant) love this sort of trip. Wanna play?

Anything which radically challenges the popular reality interpretation reference grid of ideas is dangerous, because it could destroy it, and without a grid we would be lost in a sea of meaningless information, the plight of a new-born. We all have such grids. However, not all of us are emotionally involved in them; we are willing say me to revise and critically examine them, remove defects as we find them, improve them, even discard useless or harmful parts of them. Those who do not want to are the vampires. Some vampires understand all of this, if in different terms; they use this lore for their own benefit. These are vampire lords (and ladies, if I may abuse the term?); those who do not even understand this are robots, deeply, even hopelessly, under the sway of a meme.

It is possible to reprogram the grid with calm and deliberate rational thinking and meditation and self monitoring, although old habits die hard. It is generally best to do this carefully and only concerning specific subjects or subject groups, so the grid is restructured one section at a time; a total melt down is both very difficult to achieve and totally paralyzing, probably causing a psychotic episode if achieved. The idea is self liberation, not immolation. You have to have the subconscious programs you use to live; us neuromancers redesign them to suit our tastes and needs, redesign them to be more appropriate and fun and efficient for our particular lives. This of

course makes us heretics to all the robots and vampires. We do well to keep a low profile.

Final shot: a quote from Robert A. Wilson: ``If you are not programming your own trip, who is?"

EPIGENETIC SOLUTIONS TO THE ADOPTION PROBLEM IN EVOLUTIONARY PSYCHOLOGY OR THE ADOPTION MEME

By
Dave Gross
(1993)

For those who try to examine how the pressures of natural selection have affected human behavior (an area of thinking known as "evolutionary psychology," "Darwinian psychology," "selection thinking," and probably several other terms), there have been some significant gains in understanding, but also some persistent problems.

Evolutionary psychologists try to examine human behavior from the standpoint of the theory of evolution -- to explain a human behavior by examining how that behavior contributes to the reproductive success of the individual exhibiting that behavior, and therefore to the proliferation of the genetic material which, presumably, at some level is responsible for causing that behavior. For these theorists, the problem of adoption is a thorny one -- at least when the adoption occurs outside of genetic relatives. Adoption requires a person to devote resources and energy to the upbringing of a child that carries unrelated genes.

While it has been shown that non-biological (i.e. step- or adoptive-) children are statistically treated in an inferior way by their parents than biological children are, the question remains in the case of adoption -- why are they treated well at all? Why are adoptive parents willing to put out so much time, energy and resources to help the reproductive success of a stranger?

A standard theory is that adoption, pursued mainly by otherwise childless couples, is a pathological hijacking of a parental instinct that would normally go towards encouraging the parents to raise biologically related offspring. If the parents are infertile, the psychological desires to raise a child remain and are transferred to an adopted child.

I believe that meme theory can take the pathology out of adoption, and eliminate the above awkward theory for one which uses more straightforward natural selection thinking.

The theory of evolution is based on the following facts:

- Individuals have traits which are specified genetically
- Some of these genes, and therefore traits, are passed by individuals to their offspring.
- There are variations in the genes in a population.
- Some of these genes will cause traits which make the individuals carrying them better able to propagate the genes.

Genes which have such traits will expand in the gene pool to the expense of less adapted genes. In evolutionary psychology, the restriction of natural selection thinking to the genetic level is a drawback. Memes, which can be thought of as "ideas," or "idea systems," or "systems of processing ideas," or indeed all three, also follow similar rules.

Individuals have traits (in this case, behaviors, but fashion is also a meme, so memes have the potential to shape the body as well -- the "big boobs are good" meme has shaped more than one woman's body through surgery) which are specified memetically (which isn't to say that they are permanent -- a big difference between memes and genes is that memes can be, and usually are, subject to mutation throughout the organism's lifetime. Some memes are more durable than others -- a lifetime Catholic is not unheard of, but a lifetime New Kids on the Block fan is unlikely).

Some of these memes, and therefore traits, are passed on to others. (Note: Not necessarily offspring; and in fact biological relation is only indirectly connected to meme propagation. This point is especially important to the adoption issue, and I'll go into more detail later.)

There are variations in the memes in a population (are there ever!)

Some of these memes will cause traits which make the individuals carrying the memes to be better able to propagate the meme. (A good example is a religion which encourages missionary work [read: causes the trait that we know as "missionary work"], compared to another religion which does not).

Memes which cause these traits will expand in the "meme pool" to the expense of less adapted memes.

Memes are passed epigenetically, and can be passed to people other than biological offspring.

Memes can be passed from person to person in conversation or below the level of communication "by example." Memes can even be propagated by the dead; the authors of the gospels continue to have their very successful memes read.

One way memes spread is from primary caretakers to children. The science of psychology tells us that a great deal of personality and thought is fixed in humans within the first five years of life. The primary caretakers of a child have a great opportunity to pass durable memes into their children. These memes can range from a religion or a language which is explicitly taught, to the location of the silverware drawer, which is absorbed less directly.

If the trait which encourages adoption is a genetic trait, we have the following situation (greatly simplified, of course, for illustration):

MOTHER	FATHER		
AA	BB	<- Genes	
(BIOLOGICAL CHILD)	(BIOLOGICAL CHILD)	(ADOPTED CHILD)	
AB	AB	MN	<- Genes

If the gene that encourages adoption is, for instance, a "B" gene (again, forgive the simplification) -- that gene has been passed to two biological children in the above example. Clearly, from that gene's point of view, it would be more likely to succeed if the resources

allocated to the adopted child not carrying the gene were instead allocated to the two children carrying the gene, or to the production of another child carrying the gene.

If we imagine, instead, that adoption is a memetic trait, and one which can be passed to children in the care of an adult with the trait (through religious or moral teaching, for instance), then we have the following situation:

MOTHER	FATHER		
AA	BB	<- Genes	
cc	dd	<- Memes	
(BIOLOGICAL CHILD)	(BIOLOGICAL CHILD)	(ADOPTED CHILD)	
AB	AB	MN	<- Genes
cd	cd	cd	<- Meme

So in this case, if we assume that the "c" meme was the one that encouraged the trait of adoption, that meme has not been hurt in the slightest by adoption -- in fact it has been helped. And the adoption of a child already born may be a more reliable way to get a subject for a meme than waiting for a pregnancy and the attendant possibilities of miscarriage, infant death or defect, etc.

The meme that encourages the trait of adoption, if that meme also encourages passing itself on to the possessor's children, is a meme that has a built in method of propagation to a wider and wider segment of the "meme pool." It doesn't require the possessor of the meme even to be biologically capable of having children.*

One would expect, if this meme theory of the adoption trait is true, that adoptive parents would be more likely to prefer to adopt children which A) will be more likely to absorb the adoption meme themselves, and B) will be likely to pass that meme on to other children.

As a child passes infancy and early childhood, it becomes harder to implant memes on the child. This theory would suggest, then, that adoptive parents would prefer to adopt younger children.

If a child is unlikely to reach adulthood, or if when it reaches adulthood it is unable to care for children, it will be unable to pass on memes to its children. This theory would suggest, then, that adoptive parents would prefer physically and mentally healthy children.

* Note that a possible complication of this meme becoming prominent in the "meme pool" is that it would encourage a genetic adaptation to it -- i.e. a gene which would encourage the possessor to have children and place them up for adoption, without adopting any children of the possessor's own. A gene which encouraged the possessor to put all of his/her energy into producing children which are adopted by other families would be at an advantage in such a world and would tend to counteract the adoption meme.

In fact a gene which had the effect of immunizing the bearer from the adoption meme would be a successful gene, because the possessor of that gene would be encouraged to put its resources into raising only its genetic children. On the other hand, a meme which was able to overcome this immunization would also be successful, because it would pass itself to more children (if, for

example, the possessor of that gene was unable to have biological children, the meme would survive while the gene would not)

Genes and memes are likely to be at odds like this often.

THE BLUE STAR MEME: APPLYING NATURAL SELECTION THINKING TO URBAN LEGENDS

By
Dave Gross

How does an urban legend like the "Blue Star" LSD Tattoo legend spread, why do people believe it and want to encourage other people to believe it, and what does this say about the rest of the information we encounter and form opinions about? Perhaps surprisingly, insights from Darwin's discovery of natural selection may help us answer these questions.

The principle of **natural selection** is best known for its success in explaining the evolution and variety of life. But it is not restricted in its application to living things. In short,

- if a population is composed of mortal individuals that reproduce,
- and different varieties of individuals in this population are more or less able to reproduce relative to each other,
- natural selection will take place, favoring those individuals with the greater ability to successfully reproduce versions of themselves that also successfully reproduce. Individuals with greater **reproductive success** will extend the reach of their form into future generations, at the expense of less-successful individuals.

If the individuals in the population reproduce with imperfect fidelity - if not all of the reproductions are perfect reproductions - there may occasionally be novel forms of individuals that have advantages over individuals in the existing population.

The genes that code for attributes of biological organisms fit this model well - the model was, after all, developed to explain the emergence and variety of biological organisms - but in fact the model is more general than this. Any group of **replicators** that satisfies the above criteria will be subject to natural selection - whether they are biological in nature or not.

Good ideas, slang terms, chain letters, recipes and **urban legends** are among the non-biological entities that qualify and that are subject to natural selection. They reproduce with imperfect fidelity, and some reproduce better than others, so an evolution of sorts will take place, in which certain of these cultural replicators will flourish and others will die away.

Is there an *unnatural* selection?

The adjective "natural" was put in the phrase "natural selection" to differentiate the sort of evolution caused by the selective breeding of race-horses or prize roses from the sort of evolution that happens without such conscious direction by people.

Clearly, recipes and chain letters are spread because of individual people who make conscious decisions to spread some but not others. The term "natural selection" may seem inappropriate to describe this process.

This distinction - between "natural" and "unnatural" or "directed" selection - was useful initially in explaining the theory of evolution, but it is no longer a useful distinction. *All* selection is natural selection. We are all part of nature, and if we select and breed a certain kind of sheep, it is no less natural that we should do so, than if bees, by landing on more colorful flowers, select and breed a certain kind of plant.

Furthermore, what the "Blue Star" urban legend shows us is that while the transmission of ideas may be a voluntary pursuit, people are not always conscious of the ideas they are spreading - they may believe that they are spreading an important message about a real danger when in fact they are spreading a collection of durable and virulent untruths. While a person who decides to spread such a message is acting deliberately and is selecting the message consciously - it is more accurate to say that the message has evolved into its form in order to encourage people to spread it, than to say that people have selected or "bred" the message into its form.

In Richard Dawkins's book *The Selfish Gene*, he coined the word "**meme**" to serve as the counterpart of "gene" when talking about natural selection as it applies to, in Dawkins's words, such things as "tunes, ideas, catch-phrases, clothes fashions, ways of making pots or of building arches." The name caught on, and an incipient science of "memetics" has formed around it. The "blue star" urban legend is a wonderful example of a meme, and can be compared to a **virus**, in that it briefly takes over the information reproducing abilities of a human mind - which we like to think are usually devoted to reproducing accurate, useful or at least intentionally amusing information - and uses them to reproduce more instances of itself.

How the "blue star" meme mutates

It has evolved to do this by mutating over time - the **mutations** being caused by errors, modifications and elaborations introduced when the warning message is copied. Those mutations that made people more eager to spread the warning survived and expanded in the meme pool. Examples of mutations include:

"The drug is absorbed through the skin simply by handling the paper" - This is a recent version of a phrase which several years ago read "contact with moisture and skin could cause the same effect as taking a dose of acid orally." Note how the "could" has been changed to "is" in the new version. This increases the urgency - it's not enough to tell your child not to lick the blue stars; even casual handling of an innocent-looking tattoo will cause the child to be contaminated.

"A young child could happen upon these and have a fatal 'trip'" - At some point, the warning was embellished by this note that not only are these tattoos dangerous - they can be deadly. A few years later, versions of the warning would include the phrase "young lives have already been taken" which would in turn mutate to "tattoos have already taken the lives of many young children!" At each step, the warning gets incrementally more frightening, and the importance of noticing and spreading the meme becomes more urgent.

"Please copy and post it at your work, give to friends..." - Most all of the warnings have a plea for people to reproduce the warning and to spread it. Sometimes, multiple, overlapping pleas for reproduction exist. For instance, a typical e-mail warning included the following pleas to reproduce the meme:

- "Please pass it on via e-mail."
- "Please feel free to reproduce this article and distribute it as widely as possible in your community, schools, churches and the workplace."
- "Please post it in public places and bulletin boards. Please! Get the word out as quickly as possible. This is growing faster than we can warn parents and professionals."
- "Please do your part in educating our young by being an informed parent or guardian."

"They are known to react quickly and some are laced with strychnine" - The strychnine-in-acid motif is its own urban legend, believed by many people both inside and outside of the drug culture independently from the "blue star" urban legend. This appears to be a case of cross-pollination, whereby an especially vulnerable host for information viruses was holding both of these legends simultaneously, and, noticing the commonality of LSD in both memes, combined the two. This proved to be a very popular combination and almost all warnings circulating today mention strychnine.

Sources - A number of sources and authorities have been listed as originators of the warning over the years, including specific institutions ("Beth Israel Medical Center in New York"), generic institutions ("various military organizations"), and even specific people. Almost all of the warnings found today, for whatever reason, are attributed to a "J O'Donnell" (O'Donnell being spelled sometimes with one 'n' or one 'l' or both) of "Danbury Hospital's Outpatient Chemical Dependency Treatment Service" (words sometimes rearranged or missing). Danbury Hospital in Connecticut claims that they've never had a patient or staff member by that name, but that doesn't reduce the value of the supposed authority to the meme.

Tattoo types - The various types of tattoo (in the earliest known versions just "Mickey Mouse" - but now including "blue star," Superman, Red Pyramid, Butterflies, Clowns, etc) are specifics that add credibility to the meme. Many of these are innocent-seeming images associated with child aesthetics which magnifies the horror of their hidden contamination and the likelihood that a child will be attracted to them. Many also (e.g. "Mickey Mouse," "blue star") are actual designs found on LSD blotter, which gives the legend more credibility among people who have heard about busts involving blotter acid but are confused about the difference between this and "tattoos."

Some of the mutations are less adaptive, and seem more random. "Window pane" is a term used to describe LSD distributed in a flat, translucent gelatin medium divided into a grid of squares. Sometimes mutated descriptions of "window pane" acid work their way into the flyers. Some that I've seen include:

- "Another sort is 'WINDOW PAIN' which has a grid which can be cut out."
- "...and another, that can be cut out, called WINDOW PANE which has an acid."
- "...and another called WINDOW PANE which has an acid that can be cut out."

- "Another kind called "WINDOW PANE", which has a grit that can be cut out..."

These mutations seem to be just random errors and misconceptions, resulting in nonsense that adds little to the reproductive success of the meme. The sentences that include information about "Window Pane" acid are not often found in versions of the warning seen these days, and probably got left out during reproduction when reproducers stopped being able to make any sense out of them (what's "a grit that can be cut out" anyway?).

Why people spread the meme

In the good old days, before the meme found email, it was generally reproduced without explanation or disclaimer, and so it was difficult to discover the motivations of the people doing the duplication, except through news articles about the legend in which its spreaders were interviewed. When people spread the message in e-mail or on the usenet newsgroups, however, they frequently tack on a sentence or two about why they have decided to spread the meme. These fall into a few categories. First, the "maybe it's not true, but in case it is true, I thought I should tell you:"

- "I don't know how much apparent danger there is. We just felt like we could not ignore if it was occurring. It was enough of a sufficiently gray area that I felt like I didn't want to take a chance."
- "I have not personally substantiated it, but the topic is too important to ignore out of hand."
- "[W]hether it is true or not, I thought that its content was serious enough that it warranted posting."
- "I'm just passing it on because if there is an inkling of truth, then it's important!"
- "I hope it isn't true, but I will talk to the boys about it anyway, just in case."
- Another variation of this category is "I'm going to pass it on because it sounds important" (its accuracy is not a consideration):
- "The content is so important that I want to post it here."
- "I know nothing else about these drugs, I simply posted this message when I read about it today."
- "When we hear about these things, we don't attempt to confirm or deny them. We simply send it out to emergency rooms across the region..." [*Los Angeles Times* 9 Dec 1987]
- "I felt that if it was something that concerned the safety and well-being of our students, then the parents ought to know about it."
- Then there's the "this is true" assertion sometimes masked by "we haven't seen it... yet:"
- "I don't want to start a panic wave, but I would like to point out a serious problem!" (Translated from the German)
- "We're not saying it is present in any particular community, location or school. We just want people to know that the possibility exists. "
- "This may not be in your area yet!!!! But I am passing it along as an awareness process."
- "I got this through the agency so it must be really going on in the streets."
- And there are others that are in the same neighborhood as the above two categories:
- "I do not know the source or if it is true but it sounds real enough to me."

- "You feel like if it's happening, you want to let parents know. We didn't make a big issue of it, but we wanted to pass it along."
- "I was really concerned about this. I photocopied it and gave it out to some parents."
- "With drugs, if you're going to err, it's better to do so on the side of extreme caution." (given as a justification for spreading the warning)
- "I thought about the youngsters and the children who are entrusted to me. My spontaneous reaction prevented me from verifying the veracity of this 'information.' My good faith was abused and I may have been careless." (translated from the French)

The meme is so influential that some people, even when the urban legend status of the meme is pointed out to them, refuse to abandon belief. Some point out police busts involving blotter acid and insist that this proves the legend to be true. Others attack the motives of the people debunking the legend, like one mother who wrote: "...thank you for pointing out that it is an urban legend. I'm sure all the drug dealers out there will be happy to hear that."

Others who acknowledge the mythical status of the warning, still insist that it should be spread. A participant on a parents' newsgroup wrote: "Parents aren't necessarily concerned with truth, where it could be a gray area. We are concerned with our children's safety."

People are generally baffled as to why an almost completely inaccurate warning message like this keeps spreading. From the point of view of meme theory, it makes perfect sense. Without meme theory, though, people have less satisfying theories:

Hoax - Somebody is spreading this rumor as a sick joke, spreading panic through society and laughing behind our backs.

Conspiracy - People are spreading the rumor to further demonize drug users and dealers as a way of promoting escalation of the war on drugs. (Or alternately, drug enthusiasts are spreading blatantly false anti-drug information as a way of undercutting the credibility of anti-drug messages).

Truth - Maybe the legend *is* true after all, just slightly exaggerated.

Prejudice - People are hostile toward drug users and dealers and make up stories about their evil ways in the same way that anti-semites will concoct elaborate conspiracy theories about Zionists.

Human nature - Exchanging myths is a recognized aspect of culture and this is just another example.

While some of these have an element of truth to them - prejudice does play a part in making the meme effective, elements of truth can sometimes be found in the legend itself, and spreading urban legends does seem to be a part of human nature - looking on the "blue star" urban legend from a memetic point of view makes a lot more sense and leads to much more satisfying conclusions.

The main shift in thinking that needs to take place is to look at the spread of the legend not so much from the point of view of the people who propagate the warning, but from the point of view of the warning itself. Instead of asking "what made this person want to spread this warning," ask "how did this warning acquire elements that make people want to spread it." Those memes that include elements that interest people and encourage them to spread the word will survive, reproduce and flourish at the expense of less attractive versions.

What we learn from urban legends is that people will assist in the spread of a meme regardless of its usefulness or accuracy if the meme is well-constructed and virulent - that usefulness and accuracy are not necessary elements of a successful meme.

Take notice of your own vulnerability

This legend gives us all a good opportunity to try to discover which viral memes we have been infected with. Everyone spreads some memes, and everyone has certain criteria by which they decide which ones to spread and which ones not to spread. Nobody I've ever met personally verifies the truth of every piece of information they pass on, so we're all vulnerable to memes that satisfy our reproduction criteria despite being untrue.

Some of the criteria I use when deciding whether to pass on a piece of information are:

Truth - I like to think that the information I'm sharing is accurate. If it comes from a source I respect, if I've personally verified it, or if it seems very unlikely to be false, I'm more likely to pass it on. For some memes, like jokes or puns or opinions of style, truth is not an issue at all.

Prestige - I'm more likely to spread a piece of information if spreading it will make the people who receive it think more of me (or less of my enemies or competitors). Clever jokes or anecdotes - things which paint me as a witty person - fall into this category, too.

Interest - I like to spread memes that I find to be novel, intriguing and challenging.

Correctness - I feel good about spreading memes that support my political or social viewpoints.

Importance - If I think that by passing on the meme, I'm helping to avert a crisis, or to improve the world in some way, I'm more likely to do so.

Looking at this list, and this paper, I see that memetics is a subject that seems, from personal introspection, to have a close fit with reality (**Truth**). I hope that people will read this paper and think, "Wow, what a brilliant way of looking at information!" (**Prestige**). It is a philosophy of epistemology, linguistics and information that strikes my curiosity (**Interest**). It demonstrates that popular delusions, for instance the "blue star" meme, can have a strong affect on public perceptions, and thereby a detrimental effect on government policy, for instance the drug war (**Correctness**). I think that if more people looked upon information as memes to which they may be vulnerable, they would add a level of skepticism to their information processing that would be healthy for them and for society in general (**Importance**).

I'm happy to spread the memetics meme, and I recognize it as such. I have to be aware though, that if a meme offers me enough in the prestige, interest, correctness, and importance categories, I'm vulnerable to help its spread regardless of its truth value. I also have to note that such a meme, in order to have survived long enough to encounter me, will probably be somewhat plausible and attractive (and will have fooled other people successfully), and that to the extent that I do not personally verify a meme with strengths in these categories, I will be successfully targeted by these memes.

My response to this is to do the opposite of what my inclinations are and what most people seem to do. The natural thing is, if a meme promises a great deal in non-truth-related categories, to lower the threshold of acceptance in the truth-related categories. The justifications for spreading the "blue star" meme quoted above (e.g. "I have not personally substantiated it, but the topic is too important to ignore...") are examples of this.

In light of meme theory, however, one should do just the opposite, since an untrue meme is more likely to survive and propagate if it promises a great deal in non-truth-related areas (the same goes for advertising and campaign promises) - therefore the untrue memes you encounter will probably be very tempting.

Another meme I like to spread is the "George Washington grew cannabis" meme. I strongly suspect that it's true; I've read sources that sound reasonable that claim that entries in Washington's diaries (May 12-13 and August 7, 1765 for instance) explicitly say that he was growing cannabis hemp, but I've never verified this personally, and if I were to be honest with myself, I'd have to say that the sources I've seen this information in are probably biased. But I'm tempted to take this on faith because it supports my own views that cannabis isn't so bad (**Correctness**), I think it's a curious bit of history (**Interest**), and I think it may influence people to support a more enlightened public policy toward marijuana users (**Importance**). To follow my own advice, then, I would have to be extra-skeptical about the truth of this meme.

A brief look through the alt.folklore.urban FAQ will probably show you a number of untrue bits of information that you yourself have enjoyed spreading.

For each one, try to remember why you decided to spread the information despite not being sure of its truth. By doing this, you will be able to map out the range of your vulnerability to deceptive memes. This is nothing to be ashamed of - we are **all** susceptible to this sort of memetic infection - but it is good to be aware of which categories of ideas are likely to slip past your defenses.

An important lesson that meme theory teaches that might not be learned from a non-memetics-based set of critical thinking skills is this: **An untrue idea does not have to be a lie in order to spread. Even if everybody who spreads it believes it - even if nobody benefits from people believing an untrue idea - it still may just be an effective, deceptive, memetic virus.**

Conclusion

Meme theory compels us to look upon ideas as almost independent creatures, in symbiotic relationships with our minds and our cultures. All shared ideas are memes in the cultural meme pool, and all compete for survival. Importantly, an idea's usefulness and truth are only two of several elements that lead to the survival and propagation of memes - it is possible for memes that are both useless and false to survive and prosper.

Even memes that are essentially true are frequently embellished with false details that help that meme survive in the meme pool. (For instance, I've seen newspaper articles describing LSD busts in which the seized blotter acid was described as "tattoos" - this in articles which never mentioned the "blue star" warnings. The "tattoo" reference was just a meme held by the reporter or one of the reporter's sources that found its way into the article - thereby reenforcing the "LSD comes in tattoos" meme held by anyone who read the article)

By understanding how memetic evolution works, it should be easier for you to examine those memes you encounter in your day-to-day life with a critical eye - using extra skepticism on elements of a meme that seem likely to assist in its spread.

This may help you gain a more accurate view of the world, of culture, and of human nature.

SOME REFLECTIONS ON CREATION VERSUS EVOLUTION OF MEMES

By
Dave Gross

There's a "creation vs. evolution" debate due to hit the world of memetics any time now. I can't seem to shake the impression that true individual creativity, and not just selection operating on recombinations and mutations in the social arena, is responsible for the great variety and complexity of memes that surround us.

I suspect that the counterintuitive alternative -- that the world's memes are the product of natural selection and not the accumulated treasure of creative consciousnesses -- may be an unwelcome truth in the same way that Darwin's assassination of God was unwelcome. One potential solution I came up with to explain individual creativity from a selection-oriented view is this:

People engage in an inner dialog -- a thinking process that involves the conceit of an exchange of words between actors on the subjective stage. In my case (one I don't suspect to be atypical), this dialog takes the form of different genres of drama -- sometimes arguments between advocates of opposite arguments on a position on which I am, as a whole, ambivalent; sometimes predictive role-playing in which I set up a series of actors to simulate real people from my environment confronted with different situations; etc.

My theory is that in the course of these inner dialogs, the same sort of mutations and recombinations take place as do in multi-person conversation. Each person becomes a unique evolutionary arena for memes, as some versions survive and thrive in this inner dialog and some die away.

So a person doesn't just reflect memes that they've acquired, but each person subjects each meme to a fertile inner memetic "ecosystem" before releasing it again into the social environment. This is the process by which new, novel and complex memes seem to be suddenly "created."

Unsolved is the mystery of why people think in a dialog form. It requires brains to take a thought that presumably is already in a form suitable for brain processing, compress it into a form which adds inaccuracy and ambiguity to the thought, subjectively simulate the process of hearing this compressed version out loud, translate this compressed version back into a thought, and then analyze the thought from a second point-of-view.

Perhaps this process is a form of memory, holding a thought in the delay of linguistic processing while a second personality (with a potentially valuable second opinion) is swapped in. Perhaps this is just a way of alpha-testing a linguistic formulation of a thought prior to release to see if it is as convincing as a collection of words as it is as a pre-coded thought. Or perhaps this process is a pathological form of behavior that is reinforced by parasitic memes (to whom it could potentially be very helpful).

MEMETICS: A SYSTEMS METABIOLOGY

Version 950220

By
Ron Hale-Evans
rwhe@ludism.org

Note:

This paper is close to completion, but there are still rough spots where elaboration is needed; in some places you will see notes from and to myself on what needs to be changed. I was asked by a friend to put a "pre-release" version online. Comments are very welcome and may shape the final version of this paper.

In this paper, I will present an application of general systems theory to memetics, the study of memes. Evolutionary biologist Richard Dawkins coined the word "meme" to describe the similarity of ideas to genes. Dawkins says of memes in his 1976 book *The Selfish Gene*: Examples of memes are tunes, ideas, catch-phrases, clothes fashions, and ways of making pots or of building arches. Just as genes propagate themselves in the gene pool by leaping from body to body via sperm or eggs, so memes propagate themselves in the meme pool by leaping from brain to brain via a process which, in the broad sense, can be called imitation.

Researchers have also likened memes to viruses or germs in that they often seem to come and go in waves, much as epidemics of biological organisms do. One can take Nazism as perhaps the most familiar example of what can happen when a fanatic ideology spreads and gathers many followers. The memetic plague at Jonestown proved just as fatal for the followers of Jim Jones as any biological plague would have, possibly more so. (Henson 1987)

We can use memetics as an important method for studying the spread of ideologies, religions, cults, fads, and so on. One may find it worthwhile to so consider the witch hunts of the Middle Ages, the genocide in Kampuchea, the takeover by Fundamentalist Islam in Iran, as well as the already-mentioned Nazi and Jonestown massacres, all of them ideologically or religiously (hence memetically) oriented. (Henson 1987) Fundamentalist Christian groups exist throughout the United States holding beliefs that could prove extremely dangerous in the future, especially as we approach the years 1999 and 2000. In those "odometer years" we can confidently expect to see an epidemic of apocalyptic millenarianism, just as happened in the years 999 and 1000 (Mackay 1841) and has happened to a lesser extent in recent times (Chamberlin 1975). Should an individual affected with an apocalyptic millenarian meme come into power then, as Pat Robertson threatened to in the 1988 election, the (nuclear) results could prove disastrous for the world and the human race.

Memetics, though valuable, until now has for the most part used a model of linear causation, effectively saying memes *cause* information disease, much as early germ theory said germs *cause* biological disease. This seems a stage through which all sciences seem to go, but one that we need not prolong, since we already have the foundations of a general systems theory that we can apply to most disciplines. To that end I have written this paper.

Dawkins and others usually define memes as the informational equivalent of genes. Do there exist, then, any memetic forms that act like higher biological organisms? It would appear so. Memes can propagate in isolation, but they more usually propagate in larger units which Dawkins calls "meme complexes", Hofstadter calls "schemes", and Grant calls "m-plexes". Hereafter, for simplicity, I will use the term "meme complex" to refer to this sort of organism, and the term "metabiological" to refer to its class and to the class of mental and informational phenomena of all sorts; in other words, I will define "metabiological organisms" as a kind of organism that requires a biological system for its substrate, and the more general "metaorganisms" as a kind of memetic organism that uses biological, electronic, or nanotechnological system for its substrate. (Salk 1985)

Here I will defer debate over whether we should consider given metaorganisms as memes or meme complexes by noting that just as self-replicating biological organisms can exist at many different levels of organization and complexity, from genes to cells to multicellular organisms to societies to the biosphere, so can metabiological organisms, from words to ideas to ideologies to cultures to the nösphere. For the purposes of this paper, therefore, I will define a meme as a component of a meme complex, and note that almost any meme can amount to a meme complex and vice versa. I define bits (1 and 0) as the exception; we cannot call them meme complexes since they constitute the simplest individual memetic components.

We can refer to some metaorganisms as "metaelectronic" as well as "metabiological"; in other words, they rely on electronic as well as biological substrates. This holds true for countless metaorganisms today -- for example, one might find such in the comedy routines of Monty Python. Many college and high school students know the classic routines, such as "Argument Clinic" and "The Philosophers' Song" entirely by heart and recite them on the slightest notice. Moreover, those sketches have spread from the brains of the Monty Python troupe, through television, movies, and audio recordings to millions of people around the world, into "cyberspace"; readily available computer files and programs exist that contain the material, and the Yale mainframe has a special facility for accessing them, from which they gradually migrate throughout the Internet.

The metabiological (or metaelectronic; for simplicity's sake I will continue to use only the term "metabiological") organisms known as meme complexes have many similarities to biological organisms: they mutate, they spread, evolutionary pressures select for them, and so on (Miller 1978, Lumsden and Wilson 1981, Swanson 1983, and many others). On the other hand, simple memes, as components of meme complexes, behave more like the individual units of biological heredity, genes. The analogy between memes and genes seems so striking that it tempts one to construe an actual systems isomorphism of the biological and the metabiological. Earlier proponents of memetics have acted rather cautiously in this regard. For example, Dawkins, one of the originators of memetics, believed that memes had no equivalent to alleles, as a strict isomorphism with genes would indicate they ought to. Swanson (1983), however, has pointed out that one can think of memes (or "sociogenes" as he calls them) that conflict, such as the rival ideas of Protestantism and Catholicism, as alleles.

Another biologist, Miller (1978) believes that, among other differences, there can exist no parallel to sex in memetic evolution, so that one must construe the similarity between memes and

genes as a weak analogy rather than an isomorphism. Yet perhaps one can find a parallel to sex in memetics. The avant-garde writer William S. Burroughs once said, "Language is a virus from outer space." While a language normally reproduces itself by contagion and asexually, as a virus does, languages can "mate" and produce new languages. For example, to oversimplify a bit, one can see in English the result of a cross between Old English (a Teutonic language) and early French, a Romance language. This cross occurred as a result of social intercourse between the Anglo-Saxons originally inhabiting England and the Norman invaders. There also appears to exist a memetic equivalent to the sex drive. One can see curiosity and ecumenism as urges toward mingling two or more memetic structures.

Since, as the ongoing Human Genome Project shows, we can store genetic patterns digitally (the biological becoming metabiological), one can see that genes seem merely a particular chemical reification of certain memes (namely those for building biological organisms). Both what we have been calling "memetics" and genetics, then, become subsets of the more general study of what Dawkins calls "replicators". It seems therefore something of a mistake to build memetics only by analogy to genetics; we need not a mirroring but a broadening, a generalization of both memetics and genetics to something we might call "replicatorics".

While most readers will see meme complexes as clearly metabiological, individual human personalities or egos may seem less obviously metaorganisms. Nevertheless, I will argue for this case. Perhaps one day through the emerging engineering discipline of nanotechnology, the possibility will exist of our mapping our brains in detail and uploading our minds into new, even inorganic bodies. If this proves the case, then nothing will stop individual human minds from reproducing asexually in their entirety by making "backup copies" to store in other biological or electronic media. People might see such a process as desirable. (Moravec 19??) In this way, one can see human minds as meme complexes themselves. *Les mêmes seraient memes*, so to speak. One can imagine a megalomaniac reproducing without limit and infecting new host bodies, like a virus; or perhaps a superintelligence using human personalities as "masks" for its processing capabilities so that it may interact better with intelligences of a lower order. (Lem 1984) Such superintelligences might well keep a store of human personalities and even exchange them with one another. In this way, personalities would come to differ very little from the memes we trade in contemporary commerce.

We may discover that this already occurs to a certain degree. Some metaorganisms other than human minds seem sapient and self-aware. For example, the *loa* of Haitian voodoo seem a sort of metaorganism that uses humans as *horses* or biological substrates. The same loa reappear in ceremony after ceremony: Papa Legba, Baron Samedi, and so on. More than one "copy" of a particular loa can attend a ceremony simultaneously.

These ancient meme complexes completely dominate the consciousness of their horses during the ceremony, and the horses will respond to the names of the particular loa "riding" them. Perhaps then, we can say the "software" that comprises the loa responds to interaction with others. One can argue that a loa cannot interact with humans without a human brain, and therefore does not seem intelligent of itself, but one can say the same of human minds: where can one possibly meet a human mind not presently reified in a human brain?

A similar phenomenon seems to occur in other religions and philosophies. In Christianity, it sometimes happens that a believer will become "possessed by a demon" or "filled with the Holy Spirit." In the nineteenth century there existed many "trance mediums" who would claim to speak for a "spirit"; today we know the same phenomenon as "channeling." Perhaps one can say that in a manner of speaking, there really does exist a "war in Heaven," an all-out battle for supremacy between "Christ" and "Satan," two quasi-real entities. If so, it certainly seems less clear-cut than most Christians would have it. Besides "the body of Christ" (Christianity) and "Satan" (that metaorganism which can infect or "possess" the suggestible, such as the nuns of Loudun, there exist many other metabiological entities all fighting for the ecological niches in the ideosphere: Buddha, Allah, the *kami* of Shinto, various *versions* of Christ, and so on.

Perhaps the loa and "spirits" exist independently of humans in the "ideosphere" or "nösphere". Would the Magna Carta exist even if we destroyed all paper and electronic copies of it and everyone who had ever read it had died? Answers to this question seem more the result of one's taste in ontology than falsifiable scientific hypotheses. Nevertheless, some prominent psychologists have speculated on this topic. Jung believed in a "collective unconscious", which contained all human ideas. If such does exist, then metabiological organisms must live there. Jungian archetypes may manifest themselves as mega-memes in the ideosphere or collective unconscious. Jung said that archetypes have no content. An archetype may therefore function as a sort of memetic skeleton, a meme that itself binds together clusters of memes with informational content, which may include directives of the sort discussed above.

Why do some of the metabiological phenomena discussed above manifest themselves as separate, self-conscious entities capable of reproduction, while others do not? Part of the answer to this question may lie in the way in which these metaorganisms insinuate themselves into the memetic structure of the individual human. Most often people who carry these metaorganisms become infected by them during a sudden, almost catastrophic "conversion process". This goes for the Baptist speaking in tongues as well as for the Haitian speaking as Baron Samedi. When a trance channeler seems to manifest a metaorganism but has not become infected in a traumatic conversion process, one perhaps ought to question the veracity of the experience. While the horses of Voodoo and the speakers in tongues of evangelical Christianity gain little but the temporary attention of an audience during their experience, many trance channelers make a great deal of money from their "infections," perhaps motive enough for fakery.

As an interesting sidelight, one might here want to consider a book that came out in various editions in the 1980s, titled, in fact, *War in Heaven*. This book, which author Kyle Griffith claims he "channeled," propounds the doctrine that there exist in a very real sense spiritual beings masquerading as the demons and deities of Earth's religions and that these beings compete for human souls after death, draining the *élan vital* from them for sustenance, literally eating said souls. The author seems to have a strong working knowledge of memetics; the meme complex he has constructed makes promises (of beating the bad guys) and threats (of having one's soul eaten), seems self-consistent, seems to "explain everything," (remarking upon that feature of the meme in several places so we won't fail to notice it) and has catchy names for the villains (the Theocrats) and heroes (the Invisible College). Griffith as much as admits he cribbed the idea for War in Heaven from a hoax popular in 1950s science fiction magazines known as the Shaver Mystery, which enjoyed enormous popularity.

Biologists have a motto: "Biology is destiny." Yet our memes determine our behavior no less than our genes, and becoming less "mechanical" (in the Russian mystic G.I. Gurdjieff's sense of the word (Ouspensky 19??)) entails freeing ourselves from the tyranny of both. We can probably consider some meme complexes as inherently less dogmatic and therefore making their carriers less mechanical. For example, we can probably consider agnosticism ("God may or may not exist") as less dogmatic than either fundamentalism ("God exists and He told me that...") or atheism ("God does not exist").

For every sapient being, there exist certain "unthinkable" thoughts, and these unthinkable thoughts depend on the existing memetic structure of the brain in question. One can metaphorically consider these "unthinkable thoughts" as Gödel strings for certain thinkers, in other words, patterns of information that the organism in question simply cannot express. For example, I have sometimes referred to the number 666 (the numerological equivalent of the name of the Great Beast in the biblical Book of Revelations, which one will supposedly find written on the forehead or right hand of Satan's legions during the time of the Apocalypse) as the Gödel number for Christians; many of them regard it with superstitious awe, and one hates to think what some fervent fundamentalists would do if someone stamped 666 on their foreheads as a practical joke while they slept -- suicide seems a possibility.

Let us continue with this example. Suppose a memeticist multimillionaire offers a fundamentalist Christian, an agnostic, and an atheist a million dollars apiece if they will have the number 666 tattooed on their foreheads. While the Christian would find it unthinkable to wear such a tattoo, the agnostic would find it less so, and presumably the atheist would find it a trivial matter.

I assume here that the reader does not hold to fundamentalist Christianity, and therefore does not find the prospect of such a tattoo unthinkable. Since the atheist seems the only person practically guaranteed to end up with a million dollars in pocket at the end of the experiment, does that mean that we should consider the atheism meme complex as fundamentally more liberatory than the agnostic meme complex? Not necessarily. The atheist in our *gedankenexperiment* would give the matter little thought, and in this way differs little from the Christian, who would also give the matter little thought. Only the agnostic would bother thinking through the possible consequences of the tattoo consciously, and therefore one can say that only the agnostic has come to a rational, "conscious," "non-mechanical" decision. While we can predict the responses of the Christian and the atheist beforehand with a fair degree of accuracy, the agnostic's response remains unpredictable. I therefore consider the agnostic meme complex the most liberating of the three, since it allows for the greatest leeway in action.

If we consider some memes more or less liberatory than others, then we have another, basic and personal reason for studying memetics: to achieve the greatest freedom from the meme complexes to which we humans seem no more than "horses."

According to those who work within the discipline of general semantics, one can show a correspondence between use of the verb "to be" in a text and the text's dogmatism. For example, Adolf Hitler said that Jews "are" animals, and Christians say that atheists "are" damned. The former type of use ("Jews are animals") has been termed by general semanticists the "'is' of identity" and the latter ("atheists are damned") the "'is' of predication".

Since we have as yet no objective measure of a text's dogmatism, perhaps we should temporarily take the percentage of a text that consists of forms of the verb "to be" as a measure of its dogmatism and generate some hypotheses. If one can estimate a meme's dogmatism by the number of times it uses the verb "to be," and if dogmatism contributes to a meme's virulence, then perhaps we can experimentally test the virulence of memes by counting the number of times they use the verb "to be."

I would like to venture that, all else equal, a meme that often uses the "is" of identity and the "is" of predication will prove more virulent than a meme with the same informational content that uses them less often. Perhaps one could test this by counting the number of times various versions of a meme with the same informational content use the verb "to be" and testing how randomly chosen groups rate them for plausibility and persuasiveness

In general, if the hypothesis holds, it should prove possible to create a virulence-measuring program along the lines of the grammar checker through which I ran this paper, which will count the number of times memes use various forms of the "is" of identity and the "is" of predication and generate a rough estimate of their reproductive ability thereby. (Similarly, Francis Heylighen has proposed *formality* as a measure of memetic virulence; in other words, more formal speech is more virulent than less formal speech. One could use similar methods such as computer analysis, in this instance as well.

One researcher has already performed a rough relative measure of the dogmatism of the Declaration of Independence and the Communist Manifesto by counting the appearance of the verb "to be" in (??? 198?). He suggests that we adopt the use of a subset of the English language that he calls English Prime (E-Prime or E' for short), which completely avoids the use of the verb "to be". So that the reader may judge the accuracy of this paper more dispassionately, I have written it entirely in E-Prime. Only quotations from other authors use any form of the English verb "to be".

I present, below, some of the basic factors, as I understand them, which contribute to the spread of memes. These include both factors intrinsic to the memes themselves ("hooks" (Hofstadter 1985), probably so named after the musical motifs that make hit tunes so catchy), and extrinsic, societal, political, individual and world factors.

TABLE 1: Intrinsic factors in memetic reproduction: "hooks"

1. intrinsically rewarding factors
 - 1.1. promises of reward
 - 1.2. interestingness of meme
 - 1.2.1. promises of reward
 - 1.2.2. aesthetic qualities
 - 1.2.3. humor
 - 1.2.4. strangeness/novelty
 - 1.3. feelings of superiority
 - 1.4. scapegoating
 - 1.5. explanation of everything

- 1.6. usefulness
- 1.7. self-directed reward
 - 1.7.1. unconditional reward
 - 1.7.2. for obeying
- 1.8. other-directed conditional reward
- 2. claiming intrinsically rewarding qualities
- 3. intrinsically punishing factors
 - 3.1. threats of punishment: fear
 - 3.2. guilt
 - 3.3. self-directed conditional physical harm
 - 3.4. other-directed conditional harm
- 4. mechanical factors in reproduction
 - 4.1. ease of reproduction
 - 4.1.1. simplicity
 - 4.1.2. comprehensibility
 - 4.1.3. reproductive ability of medium
 - 4.1.4. copying fidelity
 - 4.1.4.1. cohesiveness
 - 4.1.4.2. noteworthiness
 - 4.2. redundancy
 - 4.3. longevity
 - 4.4. plausibility
 - 4.5. adaptability
 - 4.5.1. syncretism
 - 4.5.1.1. subsuming other memes
 - 4.5.1.2. consistency with other memes: cooperation
 - 4.5.2. intolerance to other memes
- 4.6. precise marketing
- 5. claiming mechanical factors
- 6. general commands to host mind
 - 6.1. faith
 - 6.2. commands to explore the meme complex
 - 6.3. commands to spread the meme
 - 6.4. duty

1. Intrinsically rewarding factors: There seem to exist, from my survey, more uses of the carrot than the stick in memetic hooks, perhaps because people seem more likely to avoid memes that punish than memes that reward. People seem more likely to seek out memes that reward than memes that punish. However, memes can offer a "variable-ratio schedule of reinforcement" (Skinner 1974) that punishes more often than it rewards, yet which rewards often enough that people believe the meme and even spread it. One might see the meme that says "You can win money at Las Vegas" as a prime example.

1.1. Promises of reward: One of the ploys that memes use the most to get intelligent systems to spread them seems that of promises of reward. (Hofstadter 1985) Whether memes fulfill these promises or not seems of little consequence. (If they do, so much the better; then the meme

proves itself useful, a memetic trait we shall discuss later.) Many memes promise rewards in the indefinite future, or after death. One can see the meme complexes of many organized religions as perfect examples of this. The Christian meme says, "If you believe this meme, you will be rewarded by going to Heaven after you die." This promises reward and thus, in a way, proves intrinsically rewarding because the carriers of the meme can, in times of duress, think about the lovely, comfortable, and joyous existence promised them while in this vale of tears.

1.2. Interestingness of meme: Some memes prove successful partly because they seem interesting. A meme can seem interesting because it promises reward, of course, but can also seem interesting because carriers find it intrinsically rewarding in certain other ways: because they find it aesthetically pleasing, humorous, novel, or strange.

1.2.1. Promises of reward: See 1.1.

1.2.2. Aesthetic qualities: One might see Leonardo's *La Gioconda* (the "Mona Lisa") as a somewhat less trivial example of a meme that has spread by its aesthetic appeal, it having appeared in many unexpected places, artistic and otherwise, from Duchamp's *LHOOQ* to candy bar commercials.

1.2.3. Humor: Good examples of memes spread because of their humorous appeal seem the folk art photocopies which adorn offices and places of work all over the country.

1.2.4. Strangeness/novelty: Memes spread through strangeness or novelty probably include urban legends and ghost stories, the Discordian and SubGenius pseudo-cults of recent years, and the many Eastern religions and cults that appeared in America in the 1960s and have continued to appear and disappear to the present day.

1.3. Feelings of superiority: Another hook memetic organisms use to reward their host organisms seems the generation of feelings of superiority. *We* "are" saved; *they* "are" heathen. *We* "are" the Master Race; *they* "are" animals. The meme, of course, usually defines "we" as "vectors of this meme" and "they" as "non-vectors of this meme." The formula thus runs almost invariably, "People who carry this meme are good. People who don't carry this meme are bad. Therefore, vectors of this meme are better than non-vectors of this meme."

1.4. Scapegoating: Scapegoating seems a closely related memetic hook. By scapegoating, a group both defines itself as good and another group as bad, thus generating feelings of superiority, and seems to solve its problems at the same time. Thus Germany in the 1930s could blame all its economic problems on the Jews. Genocide, of course, solves nothing but the problem of dissent -- a problem only for those in power.

1.5. Explanation of everything: The memetic ploy of *explaining everything* seems related to scapegoating and feelings of superiority. Many of the meme complexes that have been most successful, including Marxism and Psychoanalysis as well as meme complexes more commonly recognized as religions, tend toward the all-encompassing. These "theories" and cosmologies can explain essentially all phenomena with which meme carriers come into contact in everyday life. As the philosopher of science Karl Popper pointed out (Popper 1965):

A Marxist could not open a newspaper without finding on every page confirming evidence for his interpretation of history; not only in the news, but also in its presentation--which revealed the class bias of the paper--and especially of course in what the paper did *not* say. The Freudian analysts emphasized that their theories were constantly verified by their "clinical observations".... Naturally, this all-encompassing explanation tends to have a dramatic stress-reducing effect, and in this sense, this hook (an emergent property of the meme complex itself and not usually a single meme) seems intrinsically rewarding. Moreover, the façade of usefulness that such a meme complex presents functions as a promise of reward.

More specifically, Marxism, Psychoanalysis, Christianity, Ayn Rand's currently popular philosophy of Objectivism, et al. explain too well *deviance from the meme complex*. Science seems perhaps the first meme complex in history that does not (ideally at least) explain deviance from its memes as faulty perception or reasoning that the deviant could correct by acceptance of the meme. Rather, the scientific meme complex contains the meme of the fallibility of its carriers.

1.6. Usefulness: Truly useful meme complexes exist also, as evidenced by the proliferation of life-enhancing technology since the adoption of the scientific method meme complex several hundred years ago. Moreover, useful memes extolling exercise, proper diet, hygiene, and so on have become widespread as well. Nor do scientifically based meme complexes seem the only useful ones. Through my own experience I can add that meme complexes that promote meditation seem useful in establishing a sense of well-being in the individual; and the various yoga memes also have something to recommend them. With less certainty, considering tracts such as Teresa of Avila's autobiography, I include meme complexes that promote prayer here as well, since it seems prayer may also prove useful in establishing well-being in the individual entirely apart from their promised contact with deity. Note that while certain memes in these meme complexes may prove useful, other memes within the meme complex may prove detrimental, yet they all come linked.

1.7. Self-directed reward: Some memes seem rewarding in a very concrete sense, yet one cannot call them "useful." For example, the meme that says that people ought to strive for material goods seems materially rewarding, but useful only in a trivial sense.

1.7.1. Unconditional reward: The materialism meme and other memes in the contemporary conservative meme complex seem unconditionally rewarding, at least *immediately*, and so it does not seem surprising that the complex spread so far in the 1980s. On the other hand, memes that promote kindness and development of oneself toward a spiritual ideal seem also rewarding, but not so immediately, so it should come as no surprise that these memes have traditionally been poor competitors for the memes that promote greed and self-interest (the laity has always outnumbered the relatively more ethically-advanced monks and nuns in any religion one cares to mention).

1.7.2. Reward for obeying: One would suspect that there exist also conditionally-rewarding meme complexes, i.e., memes that say, "If you obey this meme complex, you can reward yourself by method *x*," yet I can think of none. There exist, however, conditionally punishing meme complexes, as we will see below.

1.8. Other-directed conditional reward: Many memes do not reward the carriers, or do not reward the carriers alone, but reward others. They say, "Reward others who carry this meme." This way, the population as a system rewards itself for carrying the meme, and the meme gets spread. One can see this mechanism at work in the confirmation parties held by Christian parents for their children, in Bar and Bas Mitzvahs, and in any celebration organized by those people who carry the meme for those who do not or in whom the meme has not yet completely matured, such as the feast days organized by the Catholic Church for the laity.

2. Claiming intrinsically rewarding qualities: Memes need not only have any of the above hooks to possess an intrinsic reward; they need merely claim that they have these hooks, in other words, claim that they *are* useful, that they explain everything, that they *are* amusing or aesthetically interesting, and so on. The pseudoscientific meme complex of phrenology, for instance, makes claims of usefulness, and Warhol's Campbell's Soup "art" makes claims of aesthetic value. These and other claims, including the promises of reward mentioned above, seem analogous to camouflage in biological species; just as biological species have evolved to seem like other species to protect themselves, so have memetic species like the pseudosciences adopted the coloration of their legitimate cousins, the better to garner respectability, thereby attracting more followers to carry and spread their memes.

3. Intrinsically punishing factors:

3.1. Threats of punishment: fear: Not all memes seem intrinsically rewarding. Some memes punish. Analogous to the promise of reward seems the threat of punishment. Just as some memes promise you will go to Heaven if you swallow the meme, so do some, often the same ones, threaten that you will go to Hell if you do not, thus punishing disbelief by fear. Again, whether the meme can justify these claims or not has only a partial bearing on the success of the meme.

3.2. Guilt: Again analogously, memes which have adopted the strategy of "We are good; they are bad" often punish by inducing feelings of guilt ("I am bad") in the carrier should the carrier deviate from the program set forth in the meme. One suspects that this factor contributes as least as much to church attendance as does the allegedly uplifting nature of the services.

3.3. Self-directed conditional physical harm: Some memes induce the carriers to inflict physical punishment on themselves should the carriers disobey the meme; the epidemic of flagellation during the Middle Ages in Europe seems witness to this.

3.4. Other-directed conditional harm: Memes can also achieve success by inflicting punishment on others who do not carry the meme, just as they can achieve success by rewarding others who do. Jihads, crusades, witch-hunts and witch-burnings, the McCarthy-era persecution of "Communists," government persecution of "political criminals," ostracization of "nerds" by junior high-schoolers, and so on and on, seem all examples of this punishment. (It would seem unusual if a meme could achieve success by merely claiming to have the punishing qualities above; usually organisms tend to avoid entities that seem punishing.)

4. Mechanical factors in reproduction: Dawkins (1976) acknowledges three qualities of memes that make for high survival value: "longevity, fecundity, and copying-fidelity." We have

already discussed what seems to make for a fecund meme; longevity and copying-fidelity **seem**, roughly speaking, mechanical factors in the reproduction of the meme, and we will discuss them below.

4.1. Ease of reproduction: One of the primary mechanical factors in memetic spread seems that of ease of reproduction, Dawkins's "copying-fidelity" being only one aspect of this ease. Ease of reproduction has many aspects: simplicity, comprehensibility, the reproductive ability of the memetic medium, and cohesiveness. If a meme lacks any of these factors, it will lose ground and minds to the more easily duplicated memes.

4.1.1. Simplicity: That simplicity constitutes an important factor in memetic reproduction seems fairly easy to demonstrate: compare how many people can sing "Twinkle, Twinkle, Little Star" to the number of people who can recite the *Odyssey in toto*. Clearly, the simpler a meme, the less time, space, matter, and energy it will take to reproduce and the farther it will spread. Moreover, this simplicity seems a form of intrinsic reward, a hook generated as an emergent property of the whole meme or meme complex.

4.1.2. Comprehensibility: Comprehensibility also seems an important factor. One does not publish a Hindi newspaper in Sweden if one intends to reach and influence the majority of the population. Similarly, one does not put signs solely in Spanish in a Japanese airport. In fact, we seem to be evolving iconic (picture) languages for international use, computer interfaces, and so on.

4.1.3. Reproductive ability of medium: The reproductive ability of the medium that expresses the meme also has much to do with the success of the meme. One sees many of the same pieces of xerox art repeatedly in offices partly because of the spectacular reproductive ability of photocopying. People will duplicate almost any meme if it appeals to them, if there exist few or no restrictions on its duplication, and if the medium that carries it (such as 8 1/2" x 11" paper in this case) has a high reproductive ability. One acute observer of information spread, Stewart Brand, dubs this principle "information wants to be free." (Brand 1987) Other good examples of this principle include computer software piracy and the flap over Digital Audio Tape (DAT). DAT, would have allowed consumers of music to copy music they like with the fidelity of a compact disk and for the cost of a blank tape. The music industry lobbied the US federal government rather successfully to prevent DAT from being used in this way, even to the extent of placing anti-copy chips in DAT recording equipment. (Brand 1987)

4.1.4. Copying fidelity: Dawkins's "copying-fidelity" seems a fourth important factor in memetic reproduction. Copying fidelity seems crucial in preventing mutation in memes. Mutation seems not always a bad thing, of course, since through innovation (mutation), we have a rich world culture -- but in the case of useful information, any mutation seems potentially dangerous.

4.1.4.1. Cohesiveness: Poetic form seems an important early form of copying fidelity. Rhyme and meter help prevent information from decaying, and act as a primitive form of error checking. Take, for example, the well-known folk heuristic meme:

*Thirty days hath September,
April, June, and November*

Probably this meme would not have spread so far without rhyme and meter. "September" and "November" check each other in the rhyme and prevent one from substituting, say, "August."

4.1.4.2. Noteworthiness: Moreover, anything that renders a meme sufficiently noteworthy that one repeats it acts as a form of copying fidelity, another stratagem being humor, such as "My Very Educated Mother Just Served Us Nine Pumpkins" (the planets of Sol system in order away from the sun: Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, Neptune, Pluto).

4.2. Redundancy: Redundancy seems another mechanical factor in memetic reproduction that acts as a form of copying fidelity, but it also functions in another way, and so deserves a word of its own. Constant repetition of a meme increases the likelihood that those thus repeatedly exposed to it will catch it, just as someone repeatedly exposed to an influenza virus becomes more likely to catch it. "What I tell you three times is true," the Queen told Alice. This phenomenon seems partly behind one of the extrinsic factors in memetic reproduction, namely isolation of the targeted group, which we will discuss later. (Henson 1987)

4.3. Longevity: Longevity of the memetic medium seems also a factor in memetic reproduction. The more durable the medium, the longer the information it contains will survive to infect intelligent organisms. Dawkins (1976) gives as an example of the manifestation of this principle the Torah, which has survived perhaps partly so long because of the durability of written material.

4.4. Plausibility: Plausibility certainly seems a crucial factor in the reproduction of memes, at least inasmuch as they present themselves to their intended host organisms as fact and not fiction. Memes that seem true will more likely evolve and spread than memes that seem false. We have all heard the urban legends about people who took LSD in the 1960s, jumped out of windows thinking they could fly, and fell to their deaths, yet it seems unlikely, all else equal, that a meme that told of someone who took LSD and flew would spread very far in contemporary urban society, since it would seem highly implausible to listeners.

4.5. Adaptability: As with biological organisms, adaptability seems an important factor in memetic success. Memes have two main strategies available upon meeting allelic memes: they can attempt to subsume the other memes syncretistically, or they can attempt to destroy the other memes in competition.

4.5.1. Syncretism: Syncretism seems a fairly common memetic stratagem.

4.5.1.1. Subsuming other memes: Christian doctrine adopted many pagan cult figures as saints and many pagan celebrations as Church feast days, including Christmas and Easter. Buddhism subsumed many native religious symbols during its evolution in India, and Hinduism, which took over the ecological niche (or allelic position) formerly occupied by Buddhism, after the Muslim invasion destroyed much of Buddhism, syncretistically adopted the figure of the Buddha as an avatar of Vishnu, with one small catch: it said the Buddha was an avatar of Vishnu on

Earth intended to *mislead* people. In all cases of subsumption, the new meme at least relegates the old memes to an inferior position, or, to use the genetic analogy, they shift the old memes to another position so that they no longer amount to alleles of the new meme. Both the new and the old memes may then travel together.

4.5.1.2. Consistency with other memes: cooperation: Memes not occupying an allelic position can even prove helpful to new memes; they can then evolve a strategy of cooperation. In order for memes not to occupy an allelic position, they must prove consistent, or apparently consistent, with the new memes. Consistency with preexisting memes seems an important factor in a meme's success. If a meme seems consistent with old prejudices, it simply becomes another prejudice. If a person has already contracted the "We are good; they are bad" meme, and believes that their racial group (A) "is" superior to racial groups B and C, a meme that claims that racial group A "is" superior to racial group D seems likely to find easy acceptance.

4.5.2. Intolerance to other memes: Competitive destruction of other memes, however, seems at least as common as syncretism. Keith Henson points out, "From a meme's viewpoint, toleration of other memes is *not* a virtue. It is, in fact, a fatal characteristic for a particular meme, as memes inducing intolerance to other memes would soon displace it." (Henson 1987) "Monomemes" (Henson 1987) like Fundamentalist Christianity and Islam have become intolerant to most other memes and thus achieve more-or-less complete domination of the host organism, an extreme example of this domination being the "memoid", who carries a meme that overrides biological survival programs inherent in the human brain, and will risk their life to further the meme. (Henson 1987)

4.6. Precise marketing: One final characteristic commonly found in successful memes seems precise marketing. A Fundamentalist Christian meme that induces followers to recruit members from National Science Foundation meetings seems not likely to prove very successful. A meme such as that propagated by the Unification Church (the "Moonies") seems more likely to succeed when, as this meme does, it induces carriers to attempt to spread the meme among vulnerable first-year college students in a strange new environment.

5. Claiming mechanical factors: Again, it seems not always necessary for memes to have the mechanical virtues mentioned above, for example, simplicity, comprehensibility, etc., to achieve some success. The nineteenth-century planned language Volapük was enormously complex compared to its successor language, Esperanto, yet in its day Volapükists propagated it widely, merely *claiming* that it was simple and comprehensible.

6. General commands to the host mind: Some of the most successful strategies used by memes to reproduce themselves seem only peripherally related to reward and punishment. They include exhortations to blind faith, commands to spread the meme, and commands to explore the full meme complex.

6.1. Faith: Faith, says Richard Dawkins, means blind trust, in the absence of evidence, even in the teeth of evidence. The story of Doubting Thomas is told, not so that we shall admire Thomas, but so that we can admire the other apostles in comparison. Thomas demanded evidence. Nothing is more lethal for certain kinds of meme than a tendency to look for evidence. The other

apostles, whose faith was so strong that they did not need evidence, are held up to us as worthy of imitation. The meme for blind faith secures its own perpetuation by the simple unconscious expedient of discouraging rational inquiry. The meme for faith ("Believe this meme and do not question!") usually seems complemented by memes that threaten Hell and promise Heaven, so to speak, based on whether the person meeting the meme believes the meme or not.

6.2. Commands to explore the meme complex: Similar to memes which command people to believe the meme complex seem memes which command people to explore the meme complex, for example "Study the Bible with a friend this Sunday." If the person meeting this meme believes it and follows it, they will become exposed to a more complete version of the meme complex, in this case Christianity, and it seems much more likely that they will then contract it.

6.3. Commands to spread the meme: Commands to spread the meme, in other words, sentences to the effect of "spread this meme," seem one of the most common ways a meme gets its host organism to spread it. Christianity, for example, has a long history of proselytisation, and this seems partially because it has always had a memetic component that urged its spread.

Commands to spread the meme need not always be explicit. Donald Going, in (Hofstadter 1985) gives an example meme complex in which this hook develops implicitly from two explicit memes:

System X

Begin:

X1: Anyone who does not believe in System X will burn in hell.

X2: It is your duty to save others from suffering.

End.

Emerging from the two sentences in System X one can see a third, implicit sentence, "It is your duty to spread System X." Nor does the hook have to emerge from the meme complex proper. People who already believe they have a duty to save others from suffering will relatively readily spread a meme that claims that anyone who does not believe in it will burn in hell. ----- and the same holds for any claims they make, etc.!!!!

6.4. Duty: Finally, the meme of duty itself has probably been a material influence on the spread of certain meme complexes, notably militaristic ones. This meme, linked with others, such as the faith meme, as in "ours is not to wonder why," makes for a particularly virulent and dangerous meme.

TABLE 2:

EXTRINSIC FACTORS IN MEMETIC REPRODUCTION

7. input transducer

7.1. isolation

7.2. events consistent with meme

8. internal transducer

- 8.1. stresses in population increasing suggestibility
- 9. channel and net

Extrinsic factors in memetic reproduction

Memes cannot propagate in a vacuum. They need intelligent, or at least living, systems to spread them, and conditions prevailing in these systems can greatly influence their reproduction.

Miller (1978) has enumerated the major information-processing components of living systems. He calls them the input transducer, internal transducer, channel and net, decoder, associator, memory, decider, encoder, and output transducer. Below we will examine how factors related to each of these components of living systems, sometimes at the organismic level, sometimes at the societal, contribute to memetic spread.

7. Input transducer: The input transducer consists of the component of a living system that brings information into the system. In a human being this consists of the various sense organs. In a society it consists of the telecommunications devices that link it with other societies.

7.1. Isolation: As Henson points out (Henson 1987), the inputs left to a living system isolated from other inputs will tend to influence it relatively more strongly. Thus, cults such as the Unification Church tend to isolate their members from the outside world, and authoritarian governments such as the former Soviet Union, but also to some extent the US, tend to restrict the flow of memes across their borders from societies that differ greatly from their own. (Henson 1987)

7.2. Events consistent with meme: The input transducer subsystem also brings information about stressful events such as eclipses and other celestial phenomena, plagues, famines, and so on. These, particularly those phenomena that seem to fall in line with prophecy, particularly

apocalyptic prophecy such as that in the Book of Revelations in the New Testament, often have the tendency to increase suggestibility in the population, and increase susceptibility to apocalyptic memes. For example, during the Black Death in Europe there was a corresponding epidemic of millenarianism. (Barkun 1974)

8. Internal transducer: The internal transducer consists of the subsystem that gathers information about other subsystems within the system. In a human being, the nerves leading from the various organs and internal subsystems to the brain serve this function. In society, news crews, reporters, and so on serve this function.

8.1. Stresses in population increasing suggestibility: The society's internal transducer would tend to relay stresses within a population to the rest of the population. Intrasocietal stresses often make it more likely that new memes will find a niche; for instance, it seems unlikely that the Nazi meme would have found such acceptance in Germany in the 1930s had Germany not been undergoing extensive economic crises at the time.

9. Channel and net: The channel and net (or "net" for short) consist of the subsystem of a living system that transmits information to all parts of the system. In the human body, of course, this means the nervous system; on a larger scale, this means the telecommunications available to a society, including telephone, radio, television, mail, email (electronic mail), and so on.

9.1. Fitness of channel and net: The chief factor influencing memetic spread in the channel and net subsystem seems its fitness. This fitness includes, among other factors, a high information capacity, a high signal-to-noise ratio, and ease of use.

9.1.1. High information capacity: According to Miller (1978), information capacity seems one important variable in function of the net. High information capacity means that the channel and net can carry many signals at once. For example, the Pony Express could carry very many fewer letters cross-continent than today's fleets of mail planes; thus, the net can carry more signals in this way and spread more memes: propaganda, religious tracts, scientific information, and so on.

9.1.2. Signal-to-noise ratio: Signal-to-noise ratio seems another important variable in function of the net. (Miller 1978) This refers to the amount of desirable information that the channel and net subsystem can carry over the amount of undesirable information. A high signal-to-noise ratio means that the net can transmit much desirable information relative to undesirable information. Note that, for a given meme, any information that does not foster its own spread amounts to noise, no matter how important that information may seem to the recipients. Thus, if information about a recent important event overwhelms the net (death of a central political figure, moon landing, outbreak of war, announcement of a plague cure), a meme may find it a very hostile environment in which to spread.

9.1.3. Ease of use: Another important factor in memetic spread consists of easy use of the net. The easier the net to use, the more people will use it to spread memes. For example, whereas I rarely receive letters by regular US mail, I find it not uncommon to receive several personal messages in one day by the much easier to use email, or electronic mail, often bearing important new memes about technological advances. This advance in ease of use of communication has

also brought an increase in undesirable memes, of course; whereas I have only received a chain letter perhaps twice in my life by postal mail (commonly called "snailmail" by email users), I have received perhaps ten in the past two years by email.

10. Decoder: The decoder consists of the living system component that translates information input to it into a form usable internally by the system. In a human being, this component consists of part of the human brain; in society, it consists of both human brains with their literacy and language capabilities and the technology they have evolved (for instance, television sets) which allow them to receive information transmitted.

10.1. Availability of decoder units for population: One factor in the propagation of memes seems availability of decoding technology. The more technology available, the more information will individual organisms in the society prove able to receive, and memes will spread faster.

10.2. Ability of population to interpret memes: Literacy seems also an important factor in memetic reproduction, as do the factors of which and how many languages the population speaks. The better educated a population, the more memes it can interpret. (This does not necessarily mean that all memes that a well-educated population can interpret will necessarily fare well in that population; see "associator" below.)

11. Associator: The associator consists of the subsystem that carries out the first stage of learning within the system, that of forming associations between items of information. In the human being, the associator subsystem consists of the brain, and in society, it consists of schools, scientific institutions, and so on.

11.1. Suggestibility of population: The frequency with which the associator forms associations seems the major factor in its reproduction of memes; to put it another way, the suggestibility of the population seems a major factor in the spread of memes. The more suggestible the members of a society, the more memes they will contract and spread. Education can mitigate suggestibility; university students can read the *National Enquirer* but rarely do, and even then usually reject what they find within.

12. Memory: Memory consists of that subsystem by which a living system carries out the second stage of learning, storing associations and other sorts of information. In individual human beings, the brain carries out this function; in human society, both individual brains (as individuals store oral and procedural knowledge), and physical technologies, including books, tape, digital computer storage, and so on, carry out this process.

12.1. Presence of consistent memes: The presence of consistent memes in the memory of the targeted living system seems an important factor in the spread of memes. We have already discussed this factor from an intrinsic standpoint above, in the passages on adaptability of memes. Presence of inconsistent memes in memory contributes negatively to the spread of certain memes also, as already mentioned; education can have a drastically negative effect on the spread of memes that require high suggestibility in the target population.

12.2. Durability of memory: Durability of the memory also affects spread of memes, as discussed above under "longevity." The Odyssey propagated quite well as an oral tradition in ancient Greece, but it seems unlikely it would have survived until today had it not been written down at some point. Paper seems more durable a form of memory than oral repetition.

12.3. Ease of storage and recall: Ease of storage and recall seems also likely to affect the spread of memes. One can instantiate a meme in as durable a medium as one likes -- say, carving it in stone -- but if it remains inaccessible -- say, carved in stone in a Himalayan cave -- it will likely not propagate far.

13. Decider: The decider consists of the component subsystem that receives inputs of information from all other subsystems and outputs information to them that controls them. In the human being, this subsystem undoubtedly consists of the brain; at levels larger in scope, it consists of the board of directors, the papacy, the government, etc..

13.1. Favor of central authority: One of the main factors on any level influencing the spread of memes seems whether the memes being spread have already infected central authority (the decider component). If it has, the decider seems likely to put its considerable force behind the spread of the meme, and since it has information outputs leading to all systems, the meme can then spread very far. If the decider has not contracted the meme, it seems likely either to ignore the meme being spread, or to attempt to repress it, usually by spreading conflicting memes which interfere with the meme being spread (and incidentally acting as noise on the channel and net), or by punishing those who carry the meme, or both.

14. Encoder: The encoder consists of that subsystem that changes the form into it from a private form used by a system internally to a public form that other systems can use. This consists of the language centers in an individual human, and on a societal level might consist of the brain of a spokesperson for an organization, or a priest in a church.

14.1. Intelligence of those propagating the meme: The intelligence and skill of the encoder seems the main factor influencing memetic spread by encoder subsystems. Eloquence and tactfulness seem more likely to spread memes than do stammering and verbal clumsiness.

15. Output transducer: Finally, the output transducer consists of the subsystem that outputs information from the system to the environment. In a human being, this consists of the lungs and vocal tract, or the hands if writing or typing; in a larger system, it consists of the person or people proper who speak for the group, organization, or culture.

15.1. Attractiveness of those propagating the meme: One of the main factors in the spread of memes contributed by the output transducer seems the attractiveness of the output transducer. No one wants to listen to an ugly person with a screeching voice deliver homilies about Brand X Toothpaste or Brand Y Ideology, but people will listen long to a beautiful person with a mellifluous voice. Moreover, the attractiveness of the person sometimes acts as an implicit sort of promise of reward: "If you believe the meme I am spreading now, you can become as attractive as I."

Afterword

Someone once sagely said that all science consists of either physics or stamp collecting. I hope the reader has found a few interesting specimens in these pages. They hardly present a complete systems theory of memetics, but memetics has not yet outgrown its infancy, and I hope this paper has contributed to its growth.

I would like to offer my thanks to my wife Marty Hale-Evans for her extensive helpful criticism and suggestions. I would also like to thank E. Jay O'Connell... Alex Chislenko...

AN OPEN MIND IS NOT AN EMPTY MIND: EXPERIMENTS IN THE META-NOOSPHERE

By

David Hales

Journal of Artificial Societies and Social Simulation vol. 1, no. 4, 15 Oct 98

<http://www.soc.surrey.ac.uk/JASSS/1/4/2.html>

Abstract

Using the "meme" conception (Dawkins 1976) of cultural transmission and computer simulations, an exploration is made of the relationship between agents, their beliefs about their environment, communication of those beliefs, and the global behaviours that emerge in a simple artificial society. This paper builds on previous work using the Minimeme model (Bura 1994). The model is extended to incorporate open-mindedness meta-memes (memes about memes). In the scenarios presented such meta-memes have dramatic effects, increasing the optimality of population distribution and the accuracy of existing beliefs. It is argued that artificial society experimentation offers a potentially fruitful response to the inherent problems of building new meme theory.

Keywords: Artificial Societies, Computer Simulation, Memetics, Meta-memes

Introduction

1.1

If ideas are seen as replicating, mutating entities (replicating through people's minds via communication) then they can be viewed as "viruses of the mind" (Dawkins 1993). The analogy is that ideas spread through a population by "infecting" brains in a similar way to the spread of a virus. It is argued that memes are often successful because they induce their hosts to replicate them. Since Dawkins' seminal work, several other writers have used the meme concept to explain various cultural and social phenomena (Bonner 1980; Dennett 1995; Gabora 1997).

1.2

In order to investigate the implications of this conception of belief spread I have constructed a computational simulation of a simple artificial society. Several experiments have been conducted and some interesting and counter-intuitive results have been observed.

1.3

Various computational models of cultural transmission have been advanced (e.g. Axelrod 1995; Epstein and Axtell 1996; Reynolds 1994; Gabora 1995). "Cultural Algorithms" introduced by Reynolds (1994) augment standard Genetic Algorithm techniques with a belief structure of hierarchically organised beliefs and their generalisations. In the simulations he presents, group level fitness values are used to update the belief structure. The belief structure is then used to bias the selection of chromosomes for reproduction into the next generation. The model shows how cognitive abilities (generalisation in this case) and intergenerational cultural knowledge (the

belief structure) can be used to improve the performance of GAs when applied to tricky group co-operation scenarios. It is a high-level model which assumes the existence of shared cultural knowledge and group level selection. The model was not designed to address issues such as the spatial aspects of cultural transmission or the emergence of stable shared cultural characteristics from micro-level asynchronous cultural transmission and innovation. It is this latter aspect that memetic models attempt to address.

1.4

The Sugarscape (Epstein and Axtell 1996) model uses strings of binary flags to represent cultural transmission units. Each agent randomly propagates flags to local neighbours. A function is then applied to the string in order to ascribe cultural identity^[1]. The spread of such identities (or "tribes") can then be monitored and behaviours can be influenced by them (e.g. combat).

1.5

It would seem that individuals in real societies are much more active in their selection of ideas, practices and beliefs. They often reject or "repel" new ideas and beliefs, particularly if they are currently strongly attached to contradictory ones. Attachment or confidence in a particular belief may grow if many others with whom the individual has come into contact also share such a belief (a form of "reinforcement" or "frequency dependant bias" (Boyd & Richerson 1985).

1.6

A multiple agent model of meme spread which attempts to address these issues has been proposed by Bura (1994). This model is extended to incorporate meta-memes (ideas about ideas). A comparison is then made between three simulation scenarios with and without a particular meta-meme.

1.7

Gabora's (1995) "Meme and Variation" Model is a more fine grained model which utilises neural networks to capture a form of meme evaluation. In contrast, the Minimeme model described in this paper is a higher-level model. It does not make assumptions concerning agents' cognitive functioning, specifically, agents do not evaluate memes. In this sense the agents presented here are more passive than those presented by Gabora. However, evaluation mechanisms should be seen as meta-memes. The Minimeme model can accommodate evaluation mechanisms but these would be implemented as meta-memes within the system. The argument is that evaluative functioning can be "boot-strapped" from a simpler meme model without building in such functions initially. However, this is not a dogmatic statement: in general artificial societies are constructed to answer specific questions and explore particular phenomena and as such different architectures are dictated by the requirements at hand.

The Minimeme Model

2.1

The model is composed of two parts: (a) the environment and agents, (b) the meme level (or noosphere^[2]). The environments and agents differ from simulation to simulation, but the rules governing the noosphere do not.

The Noosphere

2.2

According to Dawkins (1993) any idea capable of transmitting itself from one person to another (replicating itself) is a meme. In Minimeme only memes that define behaviour are considered. Such memes can be "executed" by their hosts to produce an effect (e.g. movement, fighting, socialising etc.). In order to be successful and continue to exist, a meme must satisfy three conditions:

- it must find at least one host (an agent that stores it in its memory);
- the "execution" of the meme must not endanger the host's life (at least not before the meme has been able to reproduce itself);
- the meme must be able to resist the attack of opposing memes (termed "concurrent" memes) in the meantime.

2.3

The sum of the memories of all the agents in the environment constitutes a space called the *noosphere*. Memes inhabit the noosphere in the same way that agents inhabit the simulated environment.

How Memes Evolve and Spread

2.4

To simulate the ability of the memes to conquer a part of the noosphere two parameters are associated with each meme: "change", which is a measure of the meme's propensity to mutate or to succumb to attacks by other memes and "aggression", which is a measure of the meme's propensity to try to reproduce itself. These parameters take real values in the range [0...1]. It is important to note that these parameters do not take into account the ability of the meme to keep its agent host alive.

2.5

Mememes evolve and spread in three stages:

- Satisfaction test: update change and aggression values;
- Mutation: mutate the meme in some way;
- Replication: attempt to spread the meme to other agents.

2.6

First a satisfaction function is evaluated for each host. This function is simulation dependent. It may involve an estimation of the correct accomplishment of a task or the inspection of state variables in the host (e.g. is it hungry, ill etc.). The function should return an all-or-nothing result. Either the host is or is not satisfied. If the host is satisfied, it increases the aggression of each of its memes by 25 per cent and decreases their change by 25 per cent. Conversely, if the host is not satisfied, it decreases its memes' aggression and increases their change.

2.7

After this stage the memes may mutate and reproduce. A mutation occurs when a random draw in the range $[0..1]$ gives a number lower than the meme's change. The actual nature of the mutation is simulation dependent.

2.8

If a meme was not mutated and if another random draw in range $[0..1]$ is lower than its aggression, replication may take place. A random number of individuals are chosen among the host's neighbours (i.e. the ones it can communicate with) and the meme is proposed to each of them. If any of the neighbours are hosts to concurrent memes then a random draw in the range $[0..1]$ is made. If this is lower than the attacked meme's change the meme is overwritten by the attacking meme (*replicated*) otherwise it stays in the host's memory (*repelling* the attacking meme). If a meme tries to infect a host that already possesses the same meme it is *reinforced* (its change is decreased and its aggression is increased).

2.9

It is important to note that hosts can learn new memes only by interacting with each other. Memes can not be coded into the environment or learned by experience.

2.10

These mechanisms are the same for all the simulations using the model. The characteristics to be defined for a given simulation are: (a) The satisfaction function for the hosts; (b) The nature of the mutations each meme can undergo; (c) The range of communication between hosts (i.e. how to find the "neighbours" of a given host).

The World of the Grazers

3.1

"Grazers" are very simple agents who live in a very simple environment. They can move, feed (accumulate energy), die and communicate with others in their territory. The environment they inhabit consists of just four territories. Each territory can feed a fixed number of grazers during each cycle (a "carrying capacity"). Any number of agents can occupy a territory. Grazers have one decision to make in each cycle: whether to move to a new territory^[3] or "stay put". Grazers try to maximise their energy (if it falls below a minimum, they die). The desirability of a territory is a function of its carrying capacity and the number of grazers that already occupy it. The grazers do not have knowledge of the carrying capacities of the territories, but they do have knowledge of the distribution of the population in each territory and as "grazers" they have a natural propensity to herd. They determine the desirability of each territory based on the number of grazers already occupying it. A grazer makes a decision with reference to a meme which tells it the ideal number of grazers that should occupy a territory. It makes a rational decision using its current meme^[4]. This "herding" meme is represented by a single integer in the range 1 to 10. If a grazer possessed a '1' meme it would look for an empty territory (or the most empty if none were empty). Grazers mutate their memes by increasing or decreasing them by one.

Accumulating and Consuming Energy

3.2

Movement from one territory to another costs a grazer one energy point. If a grazer can not feed during the system cycle it loses an energy point. If a grazer can feed it gains an energy point (up to a maximum of 5 energy points). If there are more grazers in a territory than the specified carrying capacity, the grazers that will go hungry are selected at random. When the energy level of a grazer falls below 1 it dies instantly^[5]. Newly born grazers start with a maximum energy level of 5 and take their memes from a random neighbour or generate them randomly if no neighbour exists. At the start of a simulation, the locations and memes of grazers are generated randomly. All energy levels are set to the maximum.

The System Cycle

3.3

- One pass through the following phases constitutes a single system cycle^[6]:
- Action Phase: Each grazer gets a chance to move to a new territory.
- Environment Phase: Predators attack any vulnerable grazers (see below).
- Feeding Phase: Each grazer tries to eat from its current location.
- Meme Phase: Each grazer tests its satisfaction and then updates, mutates or spreads its memes (see above).

Three Simulation Scenarios

4.1

The following grazer simulation scenarios were implemented:

A

"Just Enough Food": The carrying capacities of all territories are set to 3. This means that there is one optimal distribution of agents: a 3-3-3-3 population distribution (three grazers in each territory). Such a distribution is optimal since it allows each grazer to harvest enough energy to stay alive. Intuitively one would assume that a noosphere dominated by the "3" meme would produce such an optimal solution. On reflection though, it can be seen that any noosphere totally populated with memes less than "4" should be optimal.

B

"Too Much Food": The carrying capacities of all territories are set to 4. An environmental constraint has been relaxed. This means that there are many possible optimal distributions. One might expect that such a scenario would give the grazers a better chance of finding an optimal distribution.

C

"Too Much Food with Predators": The carrying capacities are as scenario B but any territory which is occupied by less than 4 grazers is "attacked" by "predators" during the environment phase. Practically this means that all the grazers within such a territory have 2 energy points

deducted. There are four possible optimal distributions (4-4-4-0, 4-4-0-4, 4-0-4-4 and 0-4-4-4). Intuitively such a scenario seems to place heavy constraints on the possible composition of the noosphere. For example, if agents were distributed in one of these optimal arrangements it would not be stable if any one of the agents held a meme greater than "4" or less than "3". An agent holding a lower meme would move to the empty territory. An agent holding a higher meme would move to a territory holding four agents.

Experimental Methods and Presentation

5.1

For the purposes of analysis, the model is iteratively executed until a stable noosphere is attained (termed equilibrium). A stable state is one in which the composition of the noosphere stays constant over time^[7]. In such a situation "deviant" memes (those which destabilise the noosphere) will tend to be repelled and replaced by non-deviant memes through the process of replication. Such a state has parallels to the concept of an evolutionary stable strategy (Dawkins 1982). The noosphere defines the social behaviour of every agent. Any stable state could be said to be a viable social organisation (or "culture") since it persists over time even though agents may die and be replaced. Noosphere stability does not indicate the stability of other properties of the population such as death rates or the population distribution (which could be stable, seemingly random or periodic).

5.2

For each of the three scenarios, two experiments were performed, one without meta-memes and one with meta-memes (described below). Each experiment consisted of 100 simulation runs. The summary presented below (see Table 2) is therefore a synthesis of 600 individual simulation runs.

5.3

Results are presented for each experiment in the form of general observations based on a synthesis of 100 individual simulation runs. This synthesis is presented in the form of a surface contour map plotting x , y , and z as, respectively, maximum density of agents in a single territory, most dominant meme in the noosphere and total number of such couples (i.e. maximum density / dominant meme) accumulated over all simulations. Each simulation represents a point on the x, y plane. The cumulative distribution of these points is used to give a z component. This gives a contour map of the relative frequencies of stable noosphere compositions (based on the dominant meme) against an optimality measure (maximum density)^[8]. The contour maps are shown in Figures 1, 3, 4, 5, 9 and 10. In order to illustrate the dynamics of individual runs, graphs are given showing the changing composition of the noosphere and the movement of agents between locations over time (Figures 2, 6, 7 and 8).

Experiments without Meta-Memes

6.1

Each of the grazer simulation scenarios were initially executed without meta-memes.

Experiment 1a - "Just Enough Food"

6.2

By the 1,000th cycle 76 per cent of the simulation runs had reached equilibrium. By the 3,000th cycle 97 per cent had done so. Most of the runs (94%) did not result in an optimal population distribution but the results are more optimal than would be expected from a totally random distribution (see Figure 1). The "self-catalytic" ^[9] process is strongly evident.

Figure 1. Dominant meme / Maximum density synthesis

6.3

Figure 2 shows the evolution of the noosphere in a typical run. There is a speedy domination of the noosphere by the "9" meme. This takes place via the self-catalytic process in a single overpopulated territory. Notice that the single "5" meme (cycle 15 to cycle 115) lasts for about

100 cycles before succumbing to the "4" meme (which becomes dominant within another territory). The death rate is high before and after equilibrium.

Figure 2. Distribution of memes in the noosphere. Experiment 1a - Just enough food.

Equilibrium is reached at cycle 160. The single black line through the graph indicates this point (just after the elimination of the single "10" meme). At the start of the run the "9" meme quickly takes over the whole of a territory. The "5" meme manages to hold out for over 100 cycles before it is replaced by the "4" meme (dominant in its territory).

Experiment 1b - "Too Much Food"

6.4

By the 300th cycle 92 per cent of the simulation runs had found an equilibrium. By the 800th cycle all (100%) had reached equilibrium. As illustrated in Figure 3, most of these are far from optimal. Relaxation of the environment constraint significantly speeds up the self-catalytic process due to the reduced death rate.

Figure 3. Dominant meme / Maximum density synthesis

Experiment 1c - "Too Much Food with Predators"

6.5

By the 300th cycle 67 per cent of the simulation runs had found an equilibrium. By the 1000th cycle it was 92 per cent. Only 2 per cent of the simulation runs resulted in optimal population distributions (see Figure 4). The attacks of predators increased the effects of the self-catalytic process by forcing grazers into overpopulated territories. They also increased the time taken to attain equilibrium due to the increased death rate.

Figure 4. Dominant meme / Maximum density synthesis

6.6

Notice the far right grouping in Figure 4, indicating that in a significant number (32%) of simulation runs, high value memes formed an equilibrium even when all grazers were in the same territory. Consequently the average optimality of the population distribution is low (see the CAE measure given in Table 2).

Observations from the experiments

6.7

Consideration of the experiments without meta-memes leads to the following observations:

Many stable noosphere states

Many distributions of memes produce a stable noosphere. The model therefore, produces many viable "cultures" given the same conditions. One consequence of this is that misbelief is high (in

the sense of the mismatch between actual carrying capacities and the memes which predominate in the noosphere).

Optimal distributions in the minority

Most of the simulation runs produce non-optimal stabilities. This means that the death rate can be high and constant but the noosphere stays stable. This indicates that a viable "culture" is not based on the optimality of the population as a whole. In this sense memes do not need to keep agents alive to prosper.

Dynamic equilibria of population distribution

A stable noosphere does not necessarily indicate a stable population distribution. Oscillations or seemingly random movements are sometimes observed. This is interesting since it suggests that certain stable noosphere compositions accommodate complex dynamical behaviours of populations.

Killing memes can prosper

The "self-catalytic" effect of the production of aggressive "killing memes" is well described by Bura and easy enough to understand. Abstracting the observation from the specifics of the simulation we might say that: any meme that can influence an agent's behaviour in so as to reinforce and spread itself can continue to exist regardless of its side-effects. It may become dominant even if this is dysfunctional to agents individually or as a population. In the context of the model this works by mutual reinforcement. In the context of the specifics of the grazer simulations this involves getting lots of agents into one territory. This experimental evidence throws doubt on Bonner's(1980) statement concerning the possibility of successful "killing memes":

The instinct for survival is important to culture because a meme, in order to be invented or acquired must pass a severe test: If it in any way endangers the lives of the animals concerned, it will automatically be rejected. (Bonner 1980, p197)

6.8

Without some perfect evaluation function to "screen-out" killing memes, how can an animal avoid the traps that these agents have fallen into? Could meta-memes help to dampen such a process?

The Introduction of Meta-Memes into the Model

7.1

In the grazer simulations a simple unit of behaviour (herding) is represented by a meme. The meme takes the form of different varieties of herding. These memes are simply varieties of the same behaviour. We can say they are part of the same "meme family" (Bura 1994). Of course it is quite possible to have memes which influence different sorts of agent behaviour. In the context of the grazer simulations the agents are simple; they move, feed and communicate memes. In the

simulations so far, movement was determined by the herding memes held by the agents. But the grazers' handling of memes is a behaviour that can itself be mediated by memes. This is what meta-memes are. They are a subset of all possible memes which directly affect an agent's meme handling abilities. In a sense they are *ideas about ideas* ^[10].

7.2

In human society the "meme" concept is itself a meta-meme. The "scientific method" could be considered to be a high-level meta-meme (its primary function to filter other ideas, theories, beliefs etc.). But statements such as: "Do not believe what agent B believes" can also be viewed as meta-memes.

7.3

Meta-memes require high-level cognitive and communication behaviours such as language. It is hard to imagine how meta-memes could replicate via simple imitation (apart from indirectly through some side-effect of an imitated behaviour ^[11]). In these experiments meta-memes have been introduced to the model. They do not "emerge" from the model.

7.4

Meta-memes effectively allow a constraint to be turned into a variable and adapted differentially across individual agents. In the previous experiments it was found that the noosphere tends to stabilise with a variety of different memes. It is very rare for the whole noosphere to be dominated by a single meme. The introduction of meta-memes should therefore increase diversity of behaviour, specifically, behaviour related to the way agents handle memes. The population as a whole might therefore be more flexible.

7.5

The potential interaction of memes, meta-memes, agents and environment could be very complex. In order to take a step back from this complexity, analysis is best kept to population level indicators. The introduction of meta-memes could increase or decrease: (a) stability in the noosphere; (b) the death rate ^[12]; and (c) the optimality of population distribution.

Meta-Memes and the Model

7.6

In order to implement meta-memes the memory capacity of the agents is increased so they can hold one standard herding meme and one meta-meme. Standard memes and meta-memes do not compete with each other directly (i.e. a standard meme can not replace or repel a meta-meme). The standard meme is "executed" during the action phase of the system cycle whereas the meta-meme is "executed" during the meme phase. For each agent the meme phase is carried out once for the standard meme and once for the meta-meme. The size of the noosphere is therefore doubled but partitioned. One half of the noosphere is occupied by meta-memes, the other by standard memes.

The "Open-Mindedness" Meta-Meme

7.7

Intuitively one can envisage certain kinds of meta-memes that might completely "kill" noosphere dynamics. Consider a meta-meme that stops agents attempting to replicate memes or allows them to repel all memes from other agents. Such meta-memes would appear to have the potential to halt noosphere evolution. The self-referential nature of meta-memes seems to indicate that self-catalytic phenomena at a meta-level could be swifter and more disastrous to the population than those already observed.

7.8

In the context of the experiments this intuition is put to the test. An "open-mindedness" meta-meme was selected for the simulations. It has the capacity to increase an agent's probability of repelling or accepting attempted meme infections from other agents.

7.9

The "open-mindedness" meta-meme refers to a family of memes represented by the integers 1 to 10. The higher the meta-meme, the more "open-minded" the grazer possessing the meme becomes. A high value predisposes a grazer to accept memes from other grazers during an attempted infection. A low value predisposes a grazer to repel memes. A grazer with an open-mindedness meme of "6" will behave identically to a grazer without meta-memes.

7.10

In Minimeme each copy of each meme has two values associated with it: aggression and change. The change value [0..1] determines the probability that the meme will succumb to infection and be replaced by a different meme. The open-mindedness meta-meme is added to the change value (see Table 1) for the purposes of deciding if infection takes place. The value of the meta-meme can therefore be seen as a bias which is added to the change values of all memes held by the agent during an attempted infection from another agent ^[13]. In this way the probability of infection or repelling is modified by the meta-meme value. A grazer that possesses a low value meta-meme reduces the change value of all its memes ^[14]. Conversely a grazer with a high value meta-meme increases the change value of all its memes ^[15].

Table 1. Meta-meme values and biases

Meta-meme	1	2	3	4	5	6	7	8	9	10
Bias value	-1.0	-0.8	-0.6	-0.4	-0.2	0.0	+0.2	+0.4	+0.6	+0.8

Each meta-meme value is shown along with the bias it produces. This value is added to the change parameter of each meme held by the agent when an attempted infection is taking place. Note that meta-meme value "6" has a zero bias. This means that a grazer possessing a "6" meta-meme will behave in exactly the same way as a grazer with no meta-meme at all.

7.11

For a simulation with meta-memes we have two noosphere graphs (one for standard memes and one for meta-memes). The two together represent the entire noosphere. We can analyse them separately because the meta-memes and standard memes do not compete for space in the noosphere ^[16].

7.12

Since the noosphere is now twice the size, we might expect it to take longer to settle down to an equilibrium. We also might expect low value (closed-minded) meta-memes to take over the noosphere because they are self-reinforcing, whereas higher value meta-memes are self-destroying ^[17].

Experiments with Meta-Memes

8.1

The three previous experiments were performed again but with the open-mindedness meta-meme turned on.

Experiment 2a - "Just Enough Food" With Meta-Memes

8.2

By the 1,000th cycle 76 per cent (same as experiment 1a) of the simulation runs had found an equilibrium. By the 2,000th cycle it was 99 per cent (2 per cent more than experiment 1a -- an insignificant difference given the inherent randomness in the simulations). Most of the runs (87%) did not result in an optimal population distribution at equilibrium (this is only slightly better than experiment 1a). However, the non-optimal equilibria obtained were substantially more optimal (on average) than those obtained for experiment 1a (compare Figures 1 and 5). An optimality measure which takes account of dynamic population distributions can be obtained by calculating the average total cumulative deaths after equilibrium has been attained. For each of the 100 simulation runs, the number of agent deaths is measured during the last 100 cycles (during which the noosphere does not change). This value is then averaged (divided by 100). For experiment 1a this value was 18, and for experiment 2a it was 2 (see Table 2). The introduction of meta-memes has therefore increased average optimality while keeping stability about the same (i.e. time taken to attain noosphere equilibrium).

Figure 5. Dominant meme / Maximum density synthesis

8.3

Figures 6, 7 and 8 show the results of a typical simulation run. At the start of the simulation Figure 6 shows an overpopulated territory (location 3) occupied by 6 grazers. Within a few cycles this increases to 7 grazers. Figure 7 shows the self-catalytic process occurring in this territory (the high meme values). This is as observed for experiment 1a. With the introduction of meta-memes however this process is less stable and breaks-down completely around cycle 150. During the self-catalytic process the death rate is high. Notice the oscillations of high and low meta-meme values (Figure 8) up to cycle 160. These oscillations correspond to the period during which the self-catalytic process is occurring. Between cycles 30 and 50 there is an increase of low value meta-memes. By about cycle 60 however, higher value meta-memes have begun to dominate. After about cycle 100 low value meta-memes make a come back reaching a plateau around cycle 150. This meta-meme oscillation process appears to destabilises the part of the noosphere containing the standard memes. The oscillations appear to correlate with periods of high death rates. High death rates are a natural consequence of overpopulated territories and it is the self-catalytic process that forces territories to become overpopulated. The meta-meme

noosphere is stable between about cycle 140 and cycle 160. In this period movement occurs (Figure 6) and the death rate is low.

Figure 6. Distribution of the population over the four territories. Experiment 2a - Just enough food.

Notice the redistribution of the population between cycles 140 and 160.

Figure 7. Distribution of memes in the noosphere. Experiment 2a - Just enough food.
Notice the self-catalytic process and when it breaks down.

Figure 8. Distribution of memes in the noosphere. Experiment 2a - Just enough food.
Notice the oscillations and then the minor stability between cycles 140 and 160.

Experiment 2b - "Too Much Food" With Meta-Memes

8.4

By the 300th cycle 62 per cent (30 per cent less than experiment 1b) of the simulation runs had found an equilibrium. By the 1000th cycle it was 97 per cent (3 per cent less than experiment 1b). The equilibria obtained were substantially more optimal than those obtained for experiment 1b (compare Figures 3 and 9). The average total cumulative deaths after equilibrium was 2 compared to 9 for experiment 1b. The introduction of meta-memes has substantially increased the time taken to attain equilibrium but increased the optimality of those equilibria.

Figure 9. Dominant meme / Maximum density synthesis

Experiment 2c - "Too Much Food with Predators" With Meta-Memes

8.5

By the 300th cycle 19 per cent (47 per cent less than experiment 1c) of the simulation runs had found an equilibrium. By 5,000 it was 95 per cent. Only 3 per cent of the simulation runs found a

noosphere equilibrium with an optimal population distribution compared to 2 per cent for experiment 1c. The population distributions were more optimal than experiment 1c (compare Figs. 4 and 10). Notice that the far right grouping (in Figure 4) has been totally removed. This is a result of the meta-memes breaking down the most extreme manifestation of the self-catalytic process (when all grazers occupy a single territory). The mechanisms by which this process occurs are discussed in detail later but note that in such a situation (all grazers in one territory) the death rate will be very high and as such will de-stabilise the meta-meme noosphere.

Figure 10. Dominant meme / Maximum density synthesis

8.6

The introduction of meta-memes has substantially increased the time taken to attain equilibrium but increased the optimality of those equilibria significantly.

Observations and Findings

9.1

Table 2 gives a summary of the results of all the experiments. Taking averages across all three experiments, the introduction of the open-mindedness meta-meme resulted in the following (compared to experiments 1a, 1b and 1c) ^[18]:

- A decrease in the stability of the noosphere (i.e. equilibrium is reached more slowly).
- A slight increase in the number of agent deaths before equilibrium ^[19].
- An increase in the optimality of the equilibriums found.
- An increase in the "accuracy" of the dominant meme (more closely reflects the actual carrying capacities of the territories; see Figures 11a, 11b and 11c).

Table 2. A summary of results

Simulation Description	0.3	1	3	5	10	CBE	CAE
.....Experiments without meta-memes							
1a) Just enough food	49	76	97	100	100	296	18
1b) Too much food	92	100	100	100	100	22	9
1c) Too much food & predators	67	92	100	100	100	349	41
Averages	69	89	99	100	100	222	23
.....Experiments with meta-memes							
2a) Just enough food	26	76	99	99	100	173	2
2b) Too much food	62	97	100	100	100	32	2
2c) Too much food & predators	19	49	85	95	100	690	7
Averages	33	73	95	98	100	298	4

The numbered columns represent cycles (in thousands). The numbers in those columns represent the percentage of simulation runs that had reached an equilibrium by the given number of cycles. The CBE column shows the average Cumulative deaths Before Equilibrium. The CAE column shows the average Cumulative deaths After Equilibrium. After each set of three experiments the average of the columns is given.

9.2

Table 2 shows the optimality in terms of average "Cumulative deaths After Equilibrium" in the "CAE" column. The CAE value is the number of agents that died for the 100 cycles at the end of each run (during which the noosphere is stable) averaged over the 100 runs. Notice that experiment 2c (too much food with predators) has a much lower CAE at the expense of a much higher "CBE" (average Cumulative deaths Before Equilibrium). The CBE value is the number of

agents that died up to the point that equilibrium was attained averaged over the 100 runs. Comparison of Figures 4 and 10 show that the removal of the far right grouping, where all grazers stay in one territory, is responsible for the bulk of this reduction in the CAE.

What's Going On In The Meta-Noosphere?

9.3

An explanation for all the above effects which is consistent with the experimental results can be summarised as: *Two opposing processes create oscillations in the meta-meme noosphere during periods of high death rates. This causes instability and population migrations. The self-catalytic process in which killing memes prosper in overpopulated territories is generally broken after a few hundred cycles.*

9.4

The meta-meme noosphere tends to oscillate ^[21] during periods with a high death rate. This will occur whenever there is a self-catalytic process (overpopulation of a territory with high standard memes dominating it). This oscillation in the meta-meme noosphere has two effects. Firstly, a noosphere stability is prevented. This stops an equilibrium from being achieved at a point which is highly non-optimal. Secondly, the standard meme noosphere is affected when the oscillations become extreme. If the meta-meme noosphere becomes dominated by either extreme of meta-meme (highly open-minded or highly closed minded) the standard meme noosphere becomes unstable and vulnerable to dramatic changes based on mutation. This tends to push the population out of a territory where a self-catalytic process is occurring.

9.5

Oscillations in the meta-meme noosphere are caused by the interaction of two opposing processes. There are two ways in which meta-memes can increase stability in the noosphere: *High value meta-memes predominate producing increased "homogenisation"*. If a population in a given territory are strongly open-minded (high meta-meme values) then any new grazer entering the territory has a high probability of being infected with a high value meta-meme thus "converting" a potentially closed-minded grazer into an open-minded one. Such a newly converted open-minded grazer subsequently has a high probability of infection by the dominant standard meme within the territory. A deviant mutated standard meme generated from within the territory is easily suppressed due to the already open-minded nature of the grazer. The grazer tends to get quickly re-infected with the dominant standard meme for the given territory. However, if a closed-minded grazer manages to infect another host in the territory before being infected itself the territory can quickly become closed-minded.

Low value meta-memes predominate producing a closed-minded population. If low value meta-memes predominate in a given territory then all attempted infections are strongly resisted. Such a territory is however vulnerable because any new arrival into the territory (or mutation) has a high probability of being infected by a low value meta-meme making a potentially deviant standard meme resistant against infection.

9.6

Mutation is high when the death rate of a territory is high. During times of high mutation it is more likely that the vulnerabilities (outlined above) of the two stability producing processes will be exploited. When this occurs, the meta-meme noosphere tends to oscillate between the two. In effect, the open-mindedness meta-meme can stabilise the noosphere in either of the above ways but will tend to oscillate between the two when the death rate is high. This oscillation prevents equilibrium and tends to produce instability in the standard meme noosphere.

Figure 11a. Distribution of memes averaged over all the simulation runs for scenario A: "Just enough food".

The darker bars show the results of the meta-meme experiments. After the introduction of meta-memes, meme "3" representing the actual carrying capacity is favoured. Consequently the average accuracy of the memes is improved.

Figure 11b. Distribution of memes averaged over all the simulation runs

for scenario B: "Too much food".

The darker bars show the results of the meta-meme experiments. After the introduction of meta-memes, meme "4" representing the actual carrying capacity is favoured. Consequently the average accuracy of the memes is improved.

Figure 11c. Distribution of memes averaged over all the simulation runs for scenario C: "Too much food with predators".

The darker bars show the results of the meta-meme experiments. After the introduction of meta-memes, lower value memes are favoured. Consequently the average accuracy of the memes is improved.

9.7

The open-mindedness meta-meme will therefore increase the stability of the population when the death rate is low and decrease it when the death rate is high. This extra instability is functional since it produces population instabilities (movement) which generally change the death rate. If this new death rate is low enough then an equilibrium may be achieved otherwise the whole cycle will repeat. The system therefore lurches quite blindly but tends over time to increase stability and lower the death rate.

9.8

Experiment 2c (too much food with predators) has a substantially higher CBE and takes longer to find an equilibrium than did 1c. This result is due to the high death rates that such a scenario produces. This results in a constantly oscillating meta-meme noosphere which causes constant population shifts. It is therefore more difficult for the system to achieve an equilibrium. When equilibrium is attained however, it is much more optimal (the CAE drops from 41 to 7).

9.9

It was previously speculated that closed-minded (i.e. low value) meta-memes would prosper since they are self-selecting because any host that carries them is less likely to change memes through infection. Indeed the meta-meme noosphere quickly reduces to low values. However results show the "1" meta-meme is no more successful than the "2", "3" or "4" meta-memes.

Conclusions

10.1

Starting from a set of assumptions which specified a co-ordination problem based on resource harvesting and agents which individually satisfice, a memetic process was investigated. The process involved the replication, reinforcement and repelling of memes held by agents. The memes held by an agent determined its behaviour. They were exchanged via social contact between agents located within the same territory.

10.2

The original results found by Bura (1994) were reproduced indicating that memes which lead to rapid agent death can prosper by causing agents to participate in a "self-catalytic" process in which they gathered in a single territory exhausting its resources and reinforcing the very meme which brought them there. This result is at odds with Bonner's (1980) intuition.

10.3

With the addition of an open-mindedness / closed-mindedness meta-meme to the same scenario the "self-catalytic" process was destabilised resulting in less agent deaths. More optimal population distributions were found. Also the intuition that complete closed-mindedness would predominate is shown to be incorrect. These results are determined by the complex interplay of several feedback processes involving agents, resources and memes.

10.4

Much human social phenomena results from consciously planned and co-ordinated interactions. Conversely, there is much which, it is claimed, is not. It is this latter class of phenomena (which challenge rational action theory) that can benefit from a memetic treatment. The "self-catalytic" process demonstrates that human and artificial societies which consist of agents who practice "boundedly rational" and "socially docile" strategies suggested by Simon (1990) can become trapped into highly non-optimal behaviours without any knowledge of what is occurring. Also the results here demonstrate that (at least some) such traps can be avoided without necessarily requiring agents to have a high level of social knowledge and planned co-ordination.

10.5

One major result that emerged was the vast diversity of meme distributions that produced optimal stabilities and hence the easy coexistence of different views (memes) of reality. The co-evolution of several "incorrect" memes can produce fairly optimal behaviour patterns: each meme tied together through mutual correction based on incorrect views of reality. This finding can be compared to the conception of functional misbelief (Doran 1994, Doran 1998).

10.6

Why produce computational models of meme spread? In many areas of anthropology and sociology theories are constructed and described using natural language. However, the complexity of the phenomena to be explained (namely social reality) poses two fundamental problems. Firstly, natural language is often ambiguous and theories may "gloss over" important areas. Secondly, it may be impossible to test or falsify such theories because it is very difficult to collect "clean" data from real societies. This is of particular relevance to the memetics

community since the hypothesised objects of interest (memes) are difficult to track or measure. If a computational artificial society is constructed then this forces the explicit statement of assumptions in the form of a computer program. The society can then be studied (conducting experiments and collecting clean data) which hopefully can feedback or at least inform theory construction for the real social world. Experimentation in the artificial realm is neither purely inductive nor deductive but involves both (Axelrod 1997). I use the term "ceduction" (Computer Experimental Induction/Deduction) to describe this mode of investigation (Hales 1998a, Hales 1998d). This kind of speculative ceductive mode of enquiry using artificial societies is a growing area and has been embraced by sociologists, philosophers, psychologists, economists, political scientists and computer scientists in order to test and build new social theory (Conte et al, Conte & Gilbert 1995, Doran & Gilbert 1994). However, existing disciplines possess their own traditions resulting in cultural inertia and consequently slow up-take of new methodological tools. Memetics as a young and (for the most part) computationally aware discipline can utilise these factors to its benefit if it embraces this new methodology as a testing ground for new theory construction and testing. On-going work using memetic simulations to investigate altruism, group formation and stereotyping are detailed in Hales (1998b) and Hales (1998c).

10.7

Memetic models do not automatically provide any new understanding. What they do provide is a fresh perspective on an old debate and a flexible experimental and objective method to test assumptions and intuitions. Of course, the assumptions we start with are based on our own ideas of social reality. It is notoriously difficult to get hard facts or principles concerning real social systems. The social sciences are dominated by many different views of social reality. This should come as no surprise. As the meme simulations presented in this paper suggest, social reality is constructed from competing ideas which do more than just coexist, they have often co-evolved to produce global actions which are functional even though the memes (beliefs) that predominate may be objectively incorrect.

Acknowledgements

This work would not have been possible without the help, discussions and suggestions of Prof. Jim Doran, Department of Computer Science, University of Essex, Colchester, UK, and Stephane Bura, 4 Place Jussieu 75252 Paris cedex 05, France. Thanks also go to the JASSS reviewers and editors for comments and corrections and Jan Neil for lucid questioning which helped to keep me (at least partially) within the real (as opposed to the artificial) world. This work was supported by an EPSRC research studentship award. A significant proportion of this paper is based on an earlier paper (Hales 1997).

Notes

1

In the context of Sugarscape this involves counting the number of "1" digits in the string.

2

This is an apt word to use. It was first introduced in an essay written in 1949 by Teilhard de Chardin. It is used to signify the realm in which mind is exercised. Teilhard's contention was that

in the ordinary course of the evolution of living things the biosphere is being supplanted by the noosphere (Bullock 1988).

3

A grazer can move into any territory from any other.

4

If more than one territory is equally desirable then one is chosen at random.

5

Within the scenario of the grazer simulations, "birth control" is applied. In such a scheme the population is kept at a fixed size (12 in this case). A new grazer is "born" every time an old grazer dies. The new born grazer is placed within the same territory. This maintains a fixed size noosphere for the purposes of analysis.

6

The order in which agents take turns in the Action, Feeding and Meme phases of the system cycle has been randomised. This is a modification of the original Minimeme model as presented by Bura. This change was made to avoid any artefacts that might result from synchronous turn-taking (Hagselmann 1996).

7

A stable noosphere is defined as one in which no change has occurred in the last 100 cycles. Experiments have shown that after such a state is reached the noosphere generally resists attacks from mutant memes and does not evolve anymore.

8

It is important to note that such a map does not show the full picture. It deals only with the dominant meme and the territory with the maximum density. It does however, give a general picture of the major trends across all simulation runs in a digestible form.

9

This is the term used by Bura to describe the following: If a grazer holds a high value meme it will move to an overpopulated territory. By definition, the grazers in this territory will also hold high value memes. When a large enough group is formed mutual reinforcement of this meme will continue although deaths may be high if the carrying capacity of the territory is exceeded.

10

The words "idea", "belief" and "meme" are used interchangeably throughout this paper.

11

For example: A preference for a certain location could isolate an agent from exposure to memes from agents who have a preference for a different location. But this is a side-effect of the meme. A true meta-meme operates directly on the meme process.

12

There are two death rates: the initial death rate which is the number of deaths up to the point at which equilibrium is attained (these will usually be sporadic and unpredictable); and the generally constant death rate after equilibrium. Each death rate is considered separately.

13

If the result of this addition is greater than 1 or less than 0 then the result is taken to be 1 or 0 respectively.

14

This includes the open-mindedness meta-meme itself.

15

This modification process is only performed when deciding if infection should occur in the meme phase of the system cycle. The open-mindedness meta-meme has no effect on the change value during other phases (i.e. mutation). The bias values given in Table 1 are the result of applying the following formula to the meta-meme value (m):

$$\text{bias} = (m - 6) * 0.2$$

This formula was used because it delivers uniform increments, a neutral bias (meta-meme "6" = zero bias) and a fully closed minded meta-meme (meta-meme "1" = -1 bias).

16

This is a simulation specific constraint, since a grazer can not hold two standard memes or two meta-memes because they are "concurrent". Other scenarios might not have such a constraint.

17

Any low value meta-meme will make the grazer less likely to accept an attempted replication over any of its memes and this includes the meta-meme itself. A low value meta-meme (once taken by an agent) will therefore be very resistant to being replaced by replication.

18

These observations are also consistent with the results of additional experiments using a scenario based on a 2-2-2-2 carrying capacity (not enough food). Interestingly, the CAE values for these experiments were roughly equivalent to experiments 1b and 2b. The harsh environment seemed to improve the accuracy of the standard memes which compensated for the lower level of resources available.

19

This is almost entirely due to the results of experiment 2c (too much food with predators). Indeed experiment 2a (just enough food) resulted in a substantial reduction of the CBE figure.

20

All of the experiments were reproduced using a different pseudo random number generation algorithm to avoid artefacts. All the conclusions drawn are consistent with both sets of results.

For these additional results see Hales (1995). For a discussion of random number generators see Mathews (1995) and Press et al. (1992).

21

Oscillations tend to take place within the lower half of the meta-meme range ("1" to "5"). In this sense the system does select closed-minded grazer behaviour. Interestingly it does not favour the "1" meta-meme above all others.

daphal@essex.ac.uk

Gatherer (1998) makes a clear distinction between two definitions of the meme. As such it is useful in clarifying potential terminological confusion between what might be called the "internalist" or "cognitive" memeticists (using the Dawkins-B meme definition) and the "externalists" or "behavioural" memeticists (using the Dawkins-A meme definition).

The behaviourists want to operationalise memes in observable and measurable behaviours, acts and artefacts etc. Certainly anything that can't be observed or measured can not be a basis for direct empirical investigation. This, I think, is incontestable.

Gatherer attacks unconstrained theorising about "memes" that become vaguely and imprecisely equated with unobservable and unproved "neural entities". Memes then become so under-specified as to be meaningless, representing anything from sensory qualia to belief in the existence of god. Promises of a future golden age, when the neural structure of such "memes" will be revealed much like the genetic code are, as Gatherer rightly points out, no excuse for such imprecise use of terminology.

I do not agree however that from acceptance of this position we should necessarily infer that memes be seen as necessarily and always equivalent with observable and measurable phenomena. For sure, in empirical studies where memes are to be identified and tracked an operational definition based on observable and measurable phenomena must be made. Importantly however, I contend that this does not necessarily and always require us to suppose that the unit of cultural reproduction under investigation is equivalent to these observable or measurable phenomena.

It is often necessary for us to take an "intentional stance" (Dennett 1989) when observing human agents in order to make sense of their behaviour. I do not understand how we can talk about human society and individuals at a meaningful level of abstraction without reference to the "beliefs" that individuals hold. I can not make sense of why I am writing this without utilising some kind of intentional stance towards the memetics community who will read it. Presumably Gatherer believes that the Dawkins-A definition puts memetics on a more sensible footing and presumably I do not. From this abstraction a lot of things make sense. The conception of a "belief" is a powerful abstraction. Why should it be rejected a priori? Assuming that individuals have beliefs does not imply that individuals share similar neural structures and the "intentional stance" does not imply an ontological commitment to the concept of belief as such. In its weakest form we take such a "stance" to be no more than an instrumentalist device which gives the user

enhanced predictive power or understanding of some particular observable or measurable phenomena. This "stance" currently gives you some handle on why you and others are bothering to read and write all this text about memes - or does it?

Given that at some level of abstraction and from an intentional stance we can observe behaviours consistent with the assumption that individuals can communicate and spread beliefs, I fail to see why memetic theory can not be meaningfully and soundly pitched at the intentional level. The prize is to generate theory that can enhance our understanding of observable social processes and phenomena. The challenge facing memetics is that of developing such theory and empirically verifying it. Both is lacking at present. One approach to theory construction is to use computational models (see Doran 1998; Hales 1997, 1998a, 1998b, 1998c, 1998d).

In the panel discussion at the end of the first symposium on memetics at the 1st International Conference of Cybernetics in Namur (Hales 1998e) my impression was of general agreement that precise definitions were less important than examples of good memetic work. Participants also expressed that as an emerging and highly inter-disciplinary area we should be tolerant of different approaches and terminology.

Gatherer concludes his paper, arguing that memeticists should adopt the Dawkins-A definition "for the sake of intellectual survival". It is still early days and we should be more optimistic. However, in the long run if memetics cannot deliver new theory for the solution of problems which cannot be solved in other paradigms then we should not mourn but welcome its demise and move on to better frameworks.

MEMETICS

By

F. Heylighen,

Aug 18, 1994

Principia Cybernetica

- **Meme:** an information pattern, held in an individual's memory, which is capable of being copied to another individual's memory.
- **Memetics:** the theoretical and empirical science that studies the replication, spread and evolution of memes

Cultural evolution, including the evolution of knowledge, can be modelled through the same basic principles of variation and selection that underly biological evolution. This implies a shift from genes as units of biological information to a new type of units of cultural information: *memes*.

A meme is a cognitive or behavioral pattern that can be transmitted from one individual to another one. Since the individual who transmitted the meme will continue to carry it, the transmission can be interpreted as a *replication*: a copy of the meme is made in the memory of another individual, making him or her into a *carrier* of the meme. This process of self-reproduction (the memetic life-cycle), leading to spreading over a growing group of individuals, defines the meme as a replicator, similar in that respect to the gene (Dawkins, 1976; Moritz, 1991).

Dawkins listed the following three characteristics for any successful replicator:

Copying-fidelity: The more faithful the copy, the more will remain of the initial pattern after several rounds of copying. If a painting is reproduced by making photocopies from photocopies, the underlying pattern will quickly become unrecognizable.

Fecundity: The faster the rate of copying, the more the replicator will spread. An industrial printing press can churn out many more copies of a text than an office copying machine.

Longevity: The longer any instance of the replicating pattern survives, the more copies can be made of it. A drawing made by etching lines in the sand is likely to be erased before anybody could have photographed or otherwise reproduced it.

Mememes versus genes

In these general characteristics, memes are similar to genes and to other replicators, such as computer viruses or crystals. The genetic metaphor for cultural transmission is limited, though. Genes can only be transmitted from parent to child ("vertical transmission"). Memes can be transmitted between any two individuals ("horizontal transmission" or "multiple parenting"). In that sense they are more similar to parasites or infections (cf. Cullen, 1998).

For genes to be transmitted, you need a generation. Memes only take minutes to replicate, and thus have potentially much higher fecundity (see Competition between Memes and Genes). On the other hand, the copying-fidelity of memes is in general much lower. If a story is spread by being told from person to person, the final version will be very different from the original one. It is this variability or fuzziness that perhaps distinguishes cultural patterns most strikingly from DNA structures: every individual's version of an idea or belief will be in some respect different from the others'. That makes it difficult to analyse or delimit memes. This does not imply that meme evolution cannot be accurately modeled, though. After all, genetics was a well-established science long before the precise DNA structure of genes was discovered.

Examples of memes in the animal world are most bird songs, and certain techniques for hunting or using tools that are passed from parents or the social group to the youngsters (Bonner, 1980). In human society, almost any cultural entity can be seen as a meme: religions, language, fashions, songs, techniques, scientific theories and concepts, conventions, traditions, etc. The defining characteristic of memes as informational patterns is that they can be replicated in unlimited amounts by communication between individuals, independently of any replication at the level of the genes.

Modelling memes

Memetics can be defined as an approach trying to model the evolution of memes. Memes undergo processes of variation (mutation, recombination) of their internal structure. Different variants will compete for the limited memory space available in different individuals. The most fit variants will win this competition, and spread most extensively. This spreading can in principle be modelled mathematically (see e.g. Boyd & Richerson, 1985; Cavalli-Sforza & Feldman, 1981; Lumsden & Wilson, 1981; Csanyi, 1991; Lynch, 1998), although in practice it will be very difficult to determine the exact values of the parameters of the model. A more practical, qualitative approach is to formulate specific criteria for the fitness of a meme, relative to other memes, taking into account the subsequent stages of the memetic life-cycle.

As is the case with genes, it is not necessary to know the exact coding or even the exact size or boundaries of a meme in order to discuss its fitness, and thus to make predictions about its further spreading, survival or extinction within the population of competing memes. Such predictions can be empirically tested. For example, a memetic hypothesis might state that simpler memes will spread more quickly. This can be tested by observing the spread (perhaps in a controlled environment) of two memes that are similar in all respects, except that the one is simpler. Theories can also be induced from empirical observation of meme behavior "in the wild" (see e.g. Best, 1998). Given the differences in variation and selection mechanisms, it is also possible to make predictions about the competition between memes and genes.

Variation, replication and selection on the basis of meme fitness determine a complex dynamics. This dynamics will be influenced by the medium through which memes are communicated, and the copying-fidelity, fecundity and longevity it allows. Perhaps the most powerful medium for meme transmission is the computer network, and this implies some specific characteristics for memes on the net.

COMPETITION BETWEEN MEMES AND GENES

By

F. Heylighen

Aug 18, 1994

1994 Principia Cybernetica

Different mechanisms of evolution

Though memetic and genetic evolution are subjected to the same basic principles of blind variation and natural selection on the basis of fitness, memetic evolution is basically a much more flexible mechanism. Genes can only be transmitted from parents (or parent in the case of asexual reproduction) to offspring. Memes can in principle be transmitted between any two individuals (though it will become more difficult the larger the differences in cognitive mechanisms and language are). (This is sometimes called "multiple parenting").

For genes to be transmitted, you typically need one generation, which for higher organism means several years. Memes can be transmitted in the space of hours. Meme spreading is also much faster than gene spreading, because gene replication is restricted by the rather small number of offspring a single parent can have, whereas the amount of individuals that can take over a meme from a single individual is almost unlimited. Moreover, it seems much easier for memes to undergo variation, since the information in the nervous system is more plastic than that in the DNA, and since individuals can come into contact with much more different sources of novel memes. On the other hand, selection processes can be more efficient because of "vicarious" selection (Campbell, 1974): the meme carrier himself does not need to be killed in order to eliminate an inadequate meme; it can suffice that he witnesses or hears about the troubles of another individual due to that same meme.

The conclusion is that memetic evolution will be several orders of magnitude faster and more efficient than genetic evolution. It should not surprise us then that during the last ten thousand years humans have almost not changed on the genetic level, whereas their culture (i.e. the total set of memes) has undergone the most radical developments. In practice the superior "evolvability" of memes would also mean that in cases where genetic and memetic replicators are in competition, we would expect the memes to win in the long term, even though the genes would start with the advantage of a well-established, stable structure. This explains why sociobiological models of human behavior can only be partially correct, as they neglect memetic factors.

Different selection criteria

When memetic and genetic fitness criteria are inconsistent, the different implicit objectives of memes and genes will lead to a direct competition for control of the carrier's behavior. Both replicators have similar aims to the degree that they use the same vehicles: individual organisms. Everything that strengthens the vehicles should in general be good for the replicators, and hence both genes and memes should be selected on the basis of their support for increased survivability and reproducibility of their carriers. However, the implicit goals of genes and memes are

different to the degree that they use different mechanisms for spreading from one vehicle to another one. Memes will be positively selected mainly for increased *communicability*. Genes will be selected mainly for *sexual reproducibility*. These different emphases may lead to direct conflicts.

For example, priests in many religions are prohibited to marry and to have children, in striking disagreement with genetic injunctions. Yet we can easily imagine that the religious meme of celibacy would have been selected because unmarried priests can spend more time and energy on "spreading the word", and hence replicating the meme.

An even more vivid example of counter-genetic behavior, closely related to the issue of altruism, is that of martyrs, suicide teams, or kamikaze pilots, who are willing to give up their life in order to promote the spread of a meme: a religion, an ideology or a nation (i.e. a group defined by a common culture or ideology). In that case, the loss of one or a few carriers is compensated by the increased chances of survival for the other carriers or for the meme itself. For example, the suicide of an individual may attract the attention of other individuals to the meme he is carrying, and thus facilitate its spreading. A well-known example is Jan Palach, the Czech student who put himself to fire in order to protest the Soviet suppression of the "Prague Spring". In this case the meme would be the Czech version of "socialism with a human face".

STRUCTURE OF MEMES

By
F. Heylighen,
1994 Principia Cybernetica

Modelling meme units

The main criticism that can be raised against the memetic approach is that memes are difficult to define. What are the elements or units that make up a meme? Does a meme correspond to a complete symphony, or to a symphonic movement, a melody, a musical phrase, or even a single note?

In order to model meme structure, we may use some concepts from cognitive science. Perhaps the most popular unit used to represent knowledge in artificial intelligence is the production rule. It has the form "if condition, then action". In symbols:

If A, then B or $A \rightarrow B$

A represents a condition that is distinguished, B represents an action that is executed or another condition that is activated. The action leads in general to the activation of another condition. In fact a production rule can be analysed as a combination of even more primitive elements: two distinctions (which discriminate between presence and absence of the condition and the action respectively) and a connection (the "then" part, which makes the first distinction entail the second one) (Heylighen, 1991d; see also Heylighen, 1990). For example, a meme like "God is omnipotent" can be modelled as "if a phenomenon is God (distinction of God from non-God), then that phenomenon is omnipotent".

Production rules are connected when the output condition (action) of the one matches the input condition of the other. E.g. $A \rightarrow B$, $B \rightarrow C$. This makes it possible to construct complex cognitive systems on the basis of elementary rules. Even remembered melodies might be modelled in such a way, as concatenations of production rules of the type "if C (musical note distinguished), then E (note produced and subsequently distinguished)", "if E, then A", and so on.

A similar model applies to genes. A gene corresponds to a string of DNA codons, which respond to the presence of certain activating proteins or the absence of certain inhibiting proteins (condition) by manufacturing new proteins (action). This may in turn activate further genes, depending on the present of specific chemicals in the cell, and so on. This leads to complex networks of "if... then" productions (Kauffman, 1992).

Variation of memetic units

It has been shown that production rules (or at least a simplified, binary representation of them, called "classifiers") can be used to build quite impressive computer simulations of cognitive

evolution, using mutations, recombinations, and selection on the basis of "fitness" (Holland et al., 1986).

Distinctions can be represented as combinations (strings) of elementary *yes-no* (1-0) observables. Mutation or recombination of distinctions can then be modelled by either randomly changing certain binary digits in a string, or by concatenating the first part of one string (A) with the second part of another string (B), like in the following example:

A = 1001|001 mutation: A' = 1001|000
B = 0010|011 recombination ("crossing-over") of A and B:
A~B = 1000|011

Although these models do not as yet take into account distinct carriers, this looks like a very promising road to study memes formally and computationally.

Meme complexes

Even if we would model memes as connected sets of production rules, we still have the problem of how many production rules define a single meme. If we call a religion or a scientific theory a meme, it is clear that this will encompass a very large number of interconnected rules. In practice it will be impossible to enumerate all rules, or to define sharp boundaries between the rules that belong to the meme and those that do not. However, that should not detract us from using memetic mechanisms in analysing evolution.

Indeed, Darwinian models of genetic evolution have certainly proven their usefulness, even though it is in practice impossible to specify the exact DNA codons that determine the gene for, say, blue eyes or altruism towards siblings. As Dawkins (1976) notes, it is not necessary to be explicit about what are the constitutive elements of a gene, postulated to explain a particular characteristic or type of behavior. It is sufficient that we can distinguish the phenotypical effects of that gene from the effects of its rival genes (alleles). If we can determine the fitness resulting from these effects, taking into account the environment and the context of different, non-rival genes present in the genome, then we can make predictions about evolution.

The same applies to memes. If, for example, we observe that one meme (say Catholicism) induces its carriers to have more children than its competitors (say Calvinism and Anglicanism), and that the children tend to take over their memes from their parents, then, all other things being equal, we can predict that after sufficient time that meme will dominate in the population. Of course, in practice it is never the case that all other things are equal, but that is the predicament of all scientific modelling: we must always simplify, and ignore potentially important influences. The question is to do that as wisely as possible, and to maximally include relevant variables without making the model too complex.

MEMETIC SELECTION CRITERIA

By
F. Heylighen
1994 Principia Cybernetica

During the different stages of their life-cycle, memes are subjected to objective, subjective intersubjective and meme-centered selection criteria

These are the criteria that determine the overall fitness of a meme, whether it will maintain within an individual's memory and spread to other individuals, or be eliminated. As meme spreading depends on different objective, subjective and intersubjective mechanisms, the criteria are sometimes contradictory. See the general selection criteria for knowledge for more details on individual criteria.

Objective Criteria

Objective criteria denote selection by phenomena or objects independent of the hosts and memes involved in the process. The distinctiveness criterion functions mainly during the assimilation stage. It states that phenomena that are distinct, detailed or contrasted are more likely to be noticed and understood, and therefore assimilated. The invariance and controllability criteria, on the other hand, apply mainly to the retention stage. According to the invariance criterion, phenomena that recur, independently of the way in which they are perceived, are more likely to be maintained in memory. Controllability notes that phenomena which react differentially to the subject's actions are also more likely to leave a permanent memory trace.

Subjective Criteria

Subjective criteria represent selection by the subject who assimilates the meme. The main criteria at the assimilation stage are novelty (facilitates assimilation by attracting the subject's attention) and simplicity (requires less processing for the meme to be understood). The criterion of coherence (connection, consistency and support between new perception and existing memory trace) facilitates the understanding and acceptance parts of the assimilation stage, since it represents the ease with which the new meme can "fit in" with the memory that is already there. It also facilitates the retention stage since memories that cohere are more easy to retrieve and use and are therefore less likely to be forgotten. The criterion of utility, like controllability, functions mainly at the retention stage, since useful memes are more likely to be effectively used and thus reinforced, although it will also help assimilation, by making it more worthwhile for the host to do the effort to assimilate.

Intersubjective Criteria

Intersubjective criteria represent selection through the interactions between different subjects. Group utility is an emergent criterion that is implicit in all four stages: a memes that is useful to the group of all its hosts is more likely to survive because it helps the group itself to survive and

grow, and thus to absorb other individuals. Authority functions mainly at the assimilation stage: memes from authoritative sources, i.e. hosts or vehicles that are held in high regard or considered to represent expertise in the domain, will be more easily noticed and accepted. Formality (i.e. precise, unambiguous expression) too helps assimilation, at least of the original memetic content of the expression. It will contribute basically to what Dawkins (1976) calls copying-fidelity. (On the other hand, informal expression, because it tends to be simpler, may facilitate assimilation, but of an idea different from the one initially expressed). Conformity, the reinforcement of the same meme by different hosts belonging to the same group, will boost acceptance and retention (cf. Boyd & Richerson, 1985). Expressivity, the ease with which the meme can be expressed in an intersubjective medium, will obviously contribute to the expression stage. Publicity, finally, the effort put by the host(s) into the broad distribution of the message, will maximize transmission.

Meme-centered Criteria

Finally, the meme-centered criteria represent selection on the level of the meme itself. They depend only on the internal structure of the meme, not on its "fit" to external selectors, such as subjects, objects, or groups. These criteria will typically select for "selfish" (cf. Heylighen, 1992) or "parasitic" (cf. Cullen, 1998) memes, whose only goal is to spread themselves, "infecting" a maximum of hosts without regard for their hosts' well-being. This does not imply that the same meme cannot satisfy both selfish and non-selfish criteria. Religions often have this mixture of parasitic and beneficial traits (cf. Cullen, 1998)

Self-justification, the degree to which the components of a meme mutually support each other, will facilitate understanding and acceptance. Self-reinforcement, the degree to which the meme stimulates its host to rehearse itself, e.g. by repetition, meditation, prayer, etc., will strengthen retention. Intolerance, the degree to which a meme excludes rival memes from being assimilated or retained, will also help the meme to retain a stable position in memory. Proselytism, the degree to which the meme urges its host to maximally spread the meme to other hosts, will increase the rates of expression and transmission.

Stage/selector	Objective	Subjective	Inter-subjective	Meme-centered
Assimilation	distinctiveness	novelty simplicity coherence	authority formality	self-justification
Retention	invariance controllability	coherence utility	conformity	self-reinforcement intolerance
Expression			expressivity	proselytism
Transmission			publicity	proselytism

Table: a summary of the main selection criteria for memes, classified according to the stage during which they are most active, and the system responsible for the selection.

Memes as Replicators

An essential characteristic of genes, the units of biological information, is that they *replicate*: they produce copies of themselves, and thereby spread and increase in numbers. Sometimes mutations or copying errors are introduced, producing different variants. Only the best or "fittest" will manage to spread widely. This is the process of *natural selection*, which weeds out inadequate genes. Variation and selection together produce evolution, the perpetual creation of new, better adapted genes.

Richard Dawkins (1976) suggested that a similar mechanism applies to cultural information. Ideas, habits and traditions are communicated from individual to individual. This can be interpreted as a replication: a copy (possibly with errors) of the information is made in the memory of a second individual. Dawkins called the units of this cultural replication process "memes". Practically all cultural entities are memes: images, books, poems, theories, religions, language, melodies, rumours, etc. It suffices that the underlying informational or behavioral pattern is copied, e.g. when people imitate other people's habits or styles, when they learn other's ideas, or reproduce works of art. Like genes, cultural variants can be more or less successful in spreading through the population. They therefore undergo natural selection, and thus evolution.

Dawkins listed the following three characteristics for any successful replicator: 1) *copying-fidelity*: the more faithful the copy, the more will remain of the initial pattern after several rounds of copying. If a painting is reproduced by making photocopies from photocopies, the underlying pattern will quickly become unrecognizable. 2) *Fecundity*: the faster the rate of copying, the more the replicator will spread. An industrial printing press can churn out many more copies of a text than an office copying machine. 3) *Longevity*: the longer any instance of the replicating pattern survives, the more copies can be made of it. A drawing made by etching lines in the sand is likely to be erased before anybody could have photographed or otherwise reproduced it.

In these general respects, memes are similar to genes and to other replicators, like computer viruses or crystals. The genetic metaphor for cultural transmission is limited, though. Genes can only be transmitted from parent to child. Memes can be transmitted between any two individuals ("multiple parenting"). For genes to be transmitted, you need a generation. Memes only take minutes to replicate. On the other hand, the copying-fidelity of memes is in general much lower. If a story is spread by being told from person to person, the final version will be very different

from the original one. It is this variability or fuzziness that perhaps distinguishes cultural patterns most strikingly from DNA structures: every individual's version of an idea or belief will be in some respect different from the others'. That makes it difficult to define or delimit memes.

There are several selection criteria which determine in how far a particular meme will be successful. The more of these criteria a meme satisfies, the more likely it is that it will maintain and spread (Heylighen, 1993). Objective criteria determine whether the knowledge conveyed by a meme can reliably predict events in the outside world. Subjective criteria determine in how far an individual is willing to assimilate a particular meme. They include: 1) *coherence*: the meme is internally consistent, and does not contradict other beliefs the individual already has; 2) *novelty*: the meme adds something new, something remarkable, that attracts the person's attention; 3) *simplicity*: it is easy to grasp and to remember; 4) *individual utility*: the meme helps the individual to further his or her personal goals.

Intersubjective criteria determine how easily memes travel from subject to subject. They include: 5) *salience*: the meme is easily noticed by others, e.g. because it is shouted out loud, or printed on big posters; 6) *expressivity*: the meme is easily expressed in language or other codes of communication; 7) *formality*: the interpretation of the meme's expression depends little on person or context; 8) *infectiveness*: the individuals who carry the meme are inclined to "spread the word", to teach it to other people or to convert them to the belief; 9) *conformism*: the meme is supported by what the majority believe; 10) *collective utility*: the meme is useful for the group, without necessarily being useful for an individual (e.g. the traffic code).

The information in the genes of an organism constitutes its genotype. Its body, developed through the interaction of genotype with environment, constitutes its phenotype. The equivalent of a phenotype for memes is the *sociotype*, the concrete organization of the group of people carrying a collection of memes or *memotype*. For example, if the memotype is the whole of Mormon beliefs, then the sociotype is the group of all Mormons. As a meme is more fuzzy than a gene, a sociotype is likewise more fuzzy than a phenotype: it is in general not clear how a group of meme carriers can be delimited (Heylighen & Campbell, 1995).

Memes on the Net

The above review sketches the properties of memes in general, be they scientific theories, religions, musical styles or the use of gadgets. It is obvious, though, that the media by which a meme is communicated, such as scientific journals, church preachings, or radio stations, will greatly influence its eventual spread. The most important medium at present is the emerging global computer network, which can transmit any type of information to practically any place on the planet, in a negligible time.

This highly increased efficiency of transmission directly affects the dynamics of replication. Meme transmission over the network has a much higher copying-fidelity than communication through image, sound or word. Digitalisation allows the transfer of information without loss, unlike the analog mechanisms of photocopying, filming or tape recording. Fecundity too is greatly increased, since computers can produce thousands of copies of a message in very little time. Longevity, finally, becomes potentially larger, since information can be stored indefinitely

on disks or in archives. Together, these three properties ensure that memes can replicate much more efficiently via the networks. This makes the corresponding memotypes and sociotypes potentially less fuzzy.

In addition, the network transcends geographical and cultural boundaries. This means that a new development does not need to diffuse gradually from a center outwards, as, e.g., fashions or rumours do. Such diffusion can easily be stopped by different kinds of physical or linguistic barriers. On the net, an idea can appear virtually simultaneously in different parts of the world, and spread independently of the distance or proximity between senders and receivers.

The simplest example of a meme that takes into advantage these network features is a chain-letter: a message sent to different people with the express request to copy it and distribute it further. This is motivated by anticipated rewards for those who do (and punishment for those who don't). Paper chain-letters are often poorly readable photocopies, or manuscripts retyped numerous times by hand or by typewriter, with the insertion of plenty of spelling and semantic errors. The effort and cost of copying and distribution moreover limit the number of copies per generation to about 20. Chain-letters distributed by electronic mail, on the other hand, can be sent to hundreds or thousands of people at once, at virtually no efforts or costs, and without information degradation.

Though I have received more chain-letters by email than by post, chain-letters on the net are still a minor phenomenon. Although their spread is very much facilitated by the net, the same applies to all other types of messages. That means that there is increased competition between all these different memes for a limited resource: the attention a user pays to the information he or she receives. Because chain-letters fulfil relatively few of the criteria that distinguish successful memes from unsuccessful ones, they are unlikely to win this competition.

The recent development from the net as carrier of email messages to the World-Wide Web as repository of interconnected documents has greatly changed the dynamics of meme replication.

On the Web, information is no longer distributed by sending copies of files to different recipients. The information is rather stored in one particular location, the "server", where everyone can consult it. "Consultation" means that a temporary copy of the file is downloaded to the RAM memory of the user's computer, so that it can be viewed on the screen. That copy is erased as soon the user moves on to other documents. There is no need to store a permanent copy since the original will always be available. That does not mean that replicator dynamics no longer apply: the interested user will normally create a "bookmark" or "link", i.e. a pointer with the address of the original file, so that it can be easily retrieved later. A link functions as a *virtual copy* (also called an "alias" file), which produces real, but temporary, copies the moment it is activated.

The success of a web document can then be measured by the number of virtual copies or links pointing to it: the documents with most pointers will be used most extensively. There are already web robots, i.e. programs which automatically scan the Web, that make "hit parades" of the documents which are linked to most often. For example, it is likely that a reproduction of the

works of Van Gogh on the Web will be much more popular in number of pointers than the work of some unknown 20th century painter.

Cooperating Memes: towards a Global Brain?

Discussions about memes, and about evolutionary systems in general, usually emphasize *competition*, i.e. the "survival of the fittest" at the expense of the less fit. However, in biological evolution, *cooperation* between evolving systems, in the sense of symbiosis and mutual support, is at least as important. Multicellular organisms, in which the individual cells cooperate for the collective good, are a prime example.

For genes, competition is limited to "alleles": alternative versions of a gene which compete for the same position on an organism's chromosome. Genes residing in different parts of the chromosome, on the other hand, do not compete but cooperate in steering the development of the organism. Each gene produces a particular type of protein, in reaction to the presence or absence of other proteins in the cell. Together, these proteins build up the cell, digest food molecules, eliminate poisonous molecules, and generally restore the cell equilibrium after different perturbations. Genes cooperate directly through their arrangement in networks: the product of one gene can activate or deactivate a number of other genes, which in turn may activate further genes, and so on.

Similarly, memes can be said to cooperate if they are coherent or support each other. For example, the belief that the Earth is round and the belief that the Earth circles around the sun are mutually reinforcing. The "roundness" meme makes it easier to visualize the "circling" meme, and vice versa. On the other hand, the roundness meme contradicts the meme which says that the Earth is flat. Roundness and flatness behave like alleles, which compete for the same position in a person's view of the world. Though flatness does not directly contradict circling, it is clear that they fit less well together than roundness and circling. Similar examples can be found in the domains of art and fashion. Debussy's music seems to fit in much better with impressionism in painting than with expressionism. Heavy metal music seems to go together with riding motor bikes, but not so much with bicycles.

Mutually supporting memes will tend to group together in larger cooperating ensembles, like ideologies, theories or religions. Mutually exclusive ensembles, like Catholicism and Protestantism, the Copernican and Ptolemaic views of the solar system, or the hippie and punk movements, will compete for converts. It is here that the "multiple parenting" issue, distinguishing memes and genes, comes into play. Since many different people ("parents") can try to convert the same individual, that individual will need to make a choice between the different memes presented to her. (In contrast, you cannot choose from which parents you inherit your genes). For two otherwise equivalent memes, the determining characteristic will be the number of already existing converts: the more people try to convince you of something, the more likely it is that you will follow the lead. If slightly more people believe in one meme, that meme will make more new converts, and thus increase its lead over the competition. This is a self-reinforcing evolution, where success breeds success. As confirmed by a mathematical model of meme transmission (see Heylighen & Campbell, 1995), the result will be that everyone in a group ends up believing the same things. This is what I called earlier "conformist" selection.

However, different groups, with little communication between them, will generally believe different things, since conformist transmission tends to amplify small differences in initial distribution of beliefs.

Let us now see how these mechanisms of cooperation and competition are affected by the global network. Like genes, memes on the web are arranged in networks, where one document points to a number of supporting documents, which in turn link to further supporting documents. Linked documents cooperate, in the sense that they support, confirm or extend each other's ideas. Competing documents, such as announcements of commercial competitors, will not link to each other, or only refer to each other with a phrase like "you should certainly not believe what is said there".

Assuming that two competing documents are equally convincing otherwise, the competition will be won or lost by the number of links that point to each of them. The more pointers to a document can be found, the more people will consult it, and the more further pointers will be made. This is the same kind of self-reinforcing process that leads to conformism, to all members of a group settling on the same meme ensemble. The difference is that now there are no separate groups: on the global network, everyone can communicate with everyone, and every document can link to every other document. The end result is likely to be the emergence of a globally shared ideology, or "world culture", transcending the old geographical, political and religious boundaries. (Note that such homogenization of memes only results for memes that are otherwise equivalent, such as conventions, standards or codes. Beliefs differing on the other dimensions of meme selection will be much less influenced by conformist selection.) Such a networked ideology would play a role similar to that of the genome, the network of interconnected genes that stores the blueprint, and controls the physiology, of a multicellular organism. The corresponding "organism" or sociotype for this meme network would be the whole of humanity, together with its supporting technology. Individual humans would play a role similar to the organism's cells, which in principle have access to the whole of the genome, but which in practice only use that part of it necessary to fulfil their specific function.

There is a better metaphor for the emerging global network. Rather than comparing it to an organism's genome, which is normally static and evolves only because of random copying errors, it can be likened to the organism's brain, which learns and develops in a non-random way. The network functions like a nervous system for the social *superorganism* (Stock, 1993), transmitting signals between its different "organs", memorizing its experiences, making them available for retrieval when needed, and generally steering and coordinating its different functions. Thus, it might be viewed as a *global brain* (Russell, 1995).

The learning of new associations can be implemented by automating the evolutionary process which creates new links. We have set up an experiment in which a hypertext network adapts its links to the pattern of its usage by "learning" the implicit semantics of its users. Such a learning web can be made more intelligent by implementing the equivalent of "thoughts": software agents, which search the net by spreading out while following associative links, collecting information that answers the user's questions (Heylighen & Bollen, 1996). Such brain-like networks may seem far removed from our initial meme model, but they are still based on the same dynamics of variation and selection of (real or virtual) copies of information.

WHAT MAKES A MEME SUCCESSFUL? SELECTION CRITERIA FOR CULTURAL EVOLUTION

By

Francis Heylighen

CLEA, Free University of Brussels, Pleinlaan 2, B-1050 Brussels, Belgium

E-mail: fheylich@vub.ac.be,

To be published in: Proc. 15th Int. Congress on Cybernetics (Association Internat. de Cybernétique, Namur).

ABSTRACT. Meme replication is described as a 4-stage process, consisting of assimilation, retention, expression and transmission. The effect of different objective, subjective, intersubjective and meme-centered selection criteria on these different stages is discussed.

Introduction

Cultural evolution, including the evolution of knowledge, can be modelled through the same basic principles of variation and selection that underlie biological evolution (Boyd & Richerson, 1985; Cavalli-Sforza & Feldman, 1981). This implies a shift from genes as (replicating) units of biological information to a new type of (replicating) units of cultural information: *memes* (Dawkins, 1976). A meme can be defined as an information pattern, held in an individual's memory, which is capable of being copied to another individual's memory. This includes anything that can be learned or remembered: ideas, knowledge, habits, beliefs, skills, images, etc. Memetics can then be defined as the theoretical and empirical science that studies the replication, spread and evolution of memes (Moritz, 1990).

To be replicated, a meme must pass successfully through four subsequent stages: 1) assimilation by an individual, who thereby becomes a *host* of the meme; 2) retention in that individual's memory; 3) expression by the individual in language, behavior or another form that can be perceived by others; 4) transmission of the thus created message or *meme vehicle* to one or more other individuals. This last stage is followed again by stage 1, thus closing the replication loop. At each stage there is selection, meaning that some memes will be eliminated. The present paper will look in more detail at the mechanisms governing these four stages, and present a list of selection criteria that allow us to estimate the fitness of a meme relative to its competitors.

The four stages of meme replication

Assimilation

A successful meme must be able to "infect" a new host, that is, enter into its memory. Let us assume that a meme is presented to a potential new host. "Presented" means either that the individual encounters a meme vehicle, or that he or she independently discovers it, by observation of outside phenomena or by thought, i.e. recombination of existing cognitive elements. To be assimilated, the presented meme must be respectively *noticed*, *understood* and *accepted* by the host. Noticing requires that the meme vehicle be sufficiently salient to attract the host's attention. Understanding means that the host recognizes the meme as something that can

be represented in his or her cognitive system. The mind is not a blank slate on which any idea can be impressed. To be understood, a new idea or phenomenon must connect to cognitive structures that are already available to the individual. Finally, a host that has understood a new idea must also be willing to believe it or to take it serious. For example, although you are likely to understand the proposition that your car was built by little green men from Mars, you are unlikely to accept that proposition without very strong evidence. Therefore, you will in general not memorize it, and the meme will not manage to infect you.

Retention

The second stage of memetic replication is the retention of the meme in memory. By definition, memes must remain some time in memory, otherwise they cannot be called memes. The longer the meme stays, the more opportunities it will have to spread further by infecting other hosts. This is Dawkins's (1976) *longevity* characteristic for replicators.

Just like assimilation, retention is characterized by strong selection, which few memes will survive. Indeed, most of the things we hear, see or understand during the day are not stored in memory for longer than a few hours. Although you may have very clearly assimilated the news that the progressive liberal party won the Swaziland elections with 54% of the votes, you are unlikely to remember anything of this a week later--unless you live in Swaziland, perhaps. Retention will depend on how important the idea is to you, and how often it is repeated, either by recurrent perception or by internal rehearsal. All learning paradigms agree that experiences are encoded more strongly into memory by frequent reinforcement.

Expression

To be communicated to other individuals, a meme must emerge from its storage as memory pattern and enter into a physical shape that can be perceived by others. This process may be called "expression". The most obvious means of expression is speech. Other common means for meme expression are text, pictures, and behavior. Expression does not require the conscious decision of the host to communicate the meme. A meme can be expressed simply by the way somebody walks or manipulates an object, or by what he or she wears.

Some retained memes will never be expressed, for example because the host does not consider the meme interesting enough for others to know, uses it unconsciously without it showing up in his or her behavior, does not know how to express it, or wants to keep it secret. On the other hand, the host may be convinced that the meme is so important that it must be expressed again and again to everybody he or she meets.

Transmission

To reach another individual, an expression needs a physical carrier or medium which is sufficiently stable to transmit the expression without too much loss or deformation. Speech, for example, uses sound to transmit an expression, while text will be transmitted through ink on paper or electrical impulses in a wire. The expression will take the form of a physical signal, modulating the carrier into a specific shape from which the original meme can be re-derived.

This physical shape may be called the meme *vehicle*. For example, meme vehicles can be books, photographs, artefacts or CD-ROMs.

Selection at the transmission stage happens through either elimination of certain memes, when the vehicle is destroyed or gets corrupted before it is perceived by another individual, or through differential multiplication, when the vehicle is reproduced into many copies. For example, a manuscript may be put into the shredder or it may be turned into a book which is printed in thousands of copies. A radio communication may get lost because of noise, or it may be broadcasted to millions of listeners. Especially since the emergence of mass media, the transmission stage is the one where the contrast between successful and unsuccessful memes is largest, and where selection may have the largest impact.

Meme fitness

The overall survival rate of a meme m can be expressed as the meme *fitness* $F(m)$, which measures the average number of memes at moment t divided by the average number of memes at the previous time step or "generation" $t - 1$. This fitness can be expressed in a simplified model as the product of the fitnesses or survival rates for each of the four stages, respectively assimilation A , retention R , expression E and transmission T :

$$F(m) = A(m) \cdot R(m) \cdot E(m) \cdot T(m)$$

A denotes the proportion of memes vehicles encountered (or memes independently discovered) by the host that are assimilated. R represents the proportion of these assimilated memes that are retained in memory. Therefore, $A \leq 1$, $R \leq 1$. E is the number of times a retained meme is expressed by the host. T is the number of copies of an expression that is transmitted to a potential new host. Unlike A and R , E and T do not have an upper bound, although E is likely to be more restricted than T . Note that F is zero as soon as one of its components (A , R , E , T) is zero. This expresses the fact that a meme must successfully pass through *all* four stages in order to replicate. Also note that for a meme to spread ($F > 1$), you must have $E > 1$ or $T > 1$.

General Selection Criteria for Memes

Which memes will most successfully pass all these stages can be modelled by a series of selection criteria. These criteria are discussed in more detail in earlier papers (Heylighen, 1993, 1997). I will here basically situate them with respect to the four replication stages. The criteria can be grouped into different families, distinguished by the system responsible for the selection. At present, we have no method to derive the value of the fitness components from the degree to which a meme fulfils the different criteria. This does not mean that no predictions can be made, though. All other things being equal, *a meme that scores better on one of these criteria is predicted to become more numerous* in the population than a meme that scores worse.

This is a falsifiable hypothesis, which can be tested through experiments or observations. For that, it suffices to operationalize the tested criterion. This has already been done for criteria such as invariance (Van Overwalle & Heylighen, 1995), formality (Heylighen & Dewaele, 1998) or

conformity (cf. Boyd & Richerson, 1985), and seems relatively easy to do for the others as well by using standard social science methodologies, e.g. for developing test for personality traits.

Objective Criteria

Objective criteria denote selection by phenomena or objects independent of the hosts and memes involved in the process. The *distinctiveness* criterion functions mainly during the assimilation stage. It states that phenomena that are distinct, detailed or contrasted are more likely to be noticed and understood, and therefore assimilated. The *invariance* and *controllability* criteria, on the other hand, apply mainly to the retention stage. According to the invariance criterion, phenomena that recur, independently of the way in which they are perceived, are more likely to be maintained in memory. Controllability notes that phenomena which react differentially to the subject's actions are also more likely to leave a permanent memory trace.

Subjective Criteria

Subjective criteria represent selection by the subject who assimilates the meme. The main criteria at the assimilation stage are *novelty* (facilitates assimilation by attracting the subject's attention) and *simplicity* (requires less processing for the meme to be understood). The criterion of *coherence* (connection, consistency and support between new perception and existing memory trace) facilitates the understanding and acceptance parts of the assimilation stage, since it represents the ease with which the new meme can "fit in" with the memory that is already there. It also facilitates the retention stage since memories that cohere are more easy to retrieve and use and are therefore less likely to be forgotten. The criterion of *utility*, like controllability, functions mainly at the retention stage, since useful memes are more likely to be effectively used and thus reinforced, although it will also help assimilation, by making it more worthwhile for the host to do the effort to assimilate.

Intersubjective Criteria

Intersubjective criteria represent selection through the interactions between different subjects. *Group utility* is an emergent criterion that is implicit in all four stages: a memes that is useful to the group of all its hosts is more likely to survive because it helps the group itself to survive and grow, and thus to absorb other individuals. *Authority* functions mainly at the assimilation stage: memes from authoritative sources, i.e. hosts or vehicles that are held in high regard or considered to represent expertise in the domain, will be more easily noticed and accepted. *Formality* (i.e. precise, unambiguous expression) too helps assimilation, at least of the original memetic content of the expression. It will contribute basically to what Dawkins (1976) calls copying-fidelity. (On the other hand, informal expression, because it tends to be simpler, may facilitate assimilation, but of an idea different from the one initially expressed). *Conformity*, the reinforcement of the same meme by different hosts belonging to the same group, will boost acceptance and retention (cf. Boyd & Richerson, 1985). *Expressivity*, the ease with which the meme can be expressed in an intersubjective medium, will obviously contribute to the expression stage. *Publicity*, finally, the effort put by the host(s) into the broad distribution of the message, will maximize transmission.

Meme-centered Criteria

Finally, the meme-centered criteria represent selection on the level of the meme itself. They depend only on the internal structure of the meme, not on its "fit" to external selectors, such as subjects, objects, or groups. These criteria will typically select for "selfish" (cf. Heylighen, 1992) or "parasitic" (cf. Cullen, 1998) memes, whose only goal is to spread themselves, "infecting" a maximum of hosts without regard for their hosts' well-being. This does not imply that the same meme cannot satisfy both selfish and non-selfish criteria. Religions often have this mixture of parasitic and beneficial traits (cf. Cullen, 1998)

Self-justification, the degree to which the components of a meme mutually support each other, will facilitate understanding and acceptance. *Self-reinforcement*, the degree to which the meme stimulates its host to rehearse itself, e.g. by repetition, meditation, prayer, etc., will strengthen retention. *Intolerance*, the degree to which a meme excludes rival memes from being assimilated or retained, will also help the meme to retain a stable position in memory. *Proselytism*, the degree to which the meme urges its host to maximally spread the meme to other hosts, will increase the rates of expression and transmission.

<i>stages\selectors</i>	Objective	Subjective	Inter-subjective	Meme-centered
Assimilation	distinctiveness	novelty simplicity coherence	authority formality	self-justification
Retention	invariance controllability	coherence utility	conformity	self-reinforcement intolerance
Expression			expressivity	proselytism
Transmission			publicity	proselytism

Table 1: a summary of the main selection criteria for memes, classified according to the stage during which they are most active, and the system responsible for the selection.

Conclusion

This simple four stage model helps us to analyse the mechanics of meme replication, and the different requirements a meme must satisfy to spread successfully. It moreover helps us to situate and to systematize a more intuitively developed list of objective, subjective, intersubjective and meme-centered selection criteria. Although the four stage model suggests a formula for calculating memetic fitness, the theory is as yet insufficiently developed to unambiguously determine the parameters of the equation. However, the list of selection criteria does produce a range of qualitative predictions, which can be empirically tested.

**THE NECESSITY OF THEORETICAL CONSTRUCTS: A REBUTTAL OF
THE BEHAVIORIST APPROACH TO MEMETICS
A COMMENTARY ON GATHERER'S PAPER: *WHY THE THOUGH
CONTAGION METAPHOR IS RETARDING THE PROGRESS OF
MEMETICS***

By

Francis Heylighen

CLEA, Free University of Brussels, Pleinlaan 2, B-1050 Brussels, Belgium

fheylich@vub.ac.be

Derek Gatherer's (1998) thesis that the "thought contagion" metaphor has slowed down progress in memetics is clearly exposed, well-argued and based on what is obviously a broad knowledge of the most recent literature relevant to memetics. However, the epistemology underlying his argumentation is totally outdated. Although Gatherer bases his thesis on Watson's behaviourism, which was developed during the 1920's and 1930's, his philosophy that only observable entities should be part of a scientific theory goes back much further, to Comte's 19th century positivism. It was elaborated in the beginning of the 20th century by the logical positivists (or logical empiricists) of the Vienna Circle.

His view that "scientists are generally constrained by the requirement that their models should *mirror* nature" (my emphasis) is older still. It was already criticized by some of the positivists themselves, and is now completely outdated (cf. Turchin 1993). At least, Gatherer seems to be aware that this mirroring conception is problematic when he notes that quantum physicists were forced to abandon it because of "the overwhelming weight of empirical evidence".

But positivism and behaviourism too have by now been completely abandoned and discredited, the first as a methodology for science in general, the second as a methodology for psychology in particular. Popper (1959), Wittgenstein and other philosophers of science have irrefutably shown why a positivist approach cannot work. Cognitive psychology has irreversibly taken over from behaviourist psychology (although it must be said that in psychology the behaviourist position still has some influence). There is no space here to review all arguments against positivism.

Let me just mention two facts that should be obvious:

- (1) All scientific models have unobservable, theoretical constructs at their core;
- (2) All empirical research, to be in any way meaningful or useful, presupposes - explicitly or implicitly - a theoretical construct.

As evidence for proposition (1), it suffices to look at the fundamental theories of physics, the most established and empirically best supported of all sciences. Essential concepts such as quarks, electromagnetic fields, wave functions, black holes or space-time geometries are all in principle unobservable. You do not even need to consider weird, non-classical theories such as quantum physics to find unobservable entities: Newtonian mechanics, the most basic of all scientific theories, is built on the concept of "force", a mysterious, non-material entity that can only be observed indirectly through its effects on the movement of objects.

This does not mean that such theories lack empirical support. Popper (1959) has made it clear that no theory or law can ever be verified or proven by observations. However, observations are necessary to refute theories that make incorrect predictions. Thus, a theory can be considered reliable if its implications have been repeatedly tested by experiments, without being refuted. As Turchin (1993) notes, models or theories are recursive generators of predictions. The hypothesis that nucleons consist of quarks does not generate any immediately testable predictions, since quarks can by definition never be observed outside of a nucleon. However, indirectly the quark hypothesis entails other hypotheses, which entail further hypotheses, and so on, until we come to the level where a hypothesis can be tested by observation. Of course, we would like to make the path from theoretical construct to empirical test as short as possible, but if we insist on too short paths, we will be stuck with theories that have a very restricted domain of application (Turchin, 1993).

As to proposition (2), all scientists will agree that observations are only useful if they can be repeated, and if repeated observations produce similar results. But this presupposes that the different observations and their respective results are all recognized as instances of the same phenomenon. If each observation is unique, there is no regularity and thus no scientific law to be inferred. However, the only way we can decide that different observations confirm the same law is because we have a theoretical conception of what such a law could be.

Let me illustrate this principle with an example that is mentioned by Gatherer as representative of the more 'behaviourist' field of social contagion: Phillips' (1974) test of the hypothesis that subjects who hear about others committing suicide are more likely to commit suicide themselves. At first sight, this seems a good illustration of Gatherer's view of a meme as a replicating behaviour: suicide in one person leads to suicide in another person. No need to postulate unobservable constructs, such as a "mnemon" for suicide, you might think.

The first difficulty with this view is that there is no simple, unique "suicide behaviour". You can commit suicide in millions of different ways: by drinking poison, inhaling gas, shooting yourself with a gun, jumping from a cliff, or driving at high speed into a wall. All these types of behaviour look utterly different to the observer. Yet, we would all classify them as "suicide". You might argue that they all lead to a person's heart stopping to beat, an unambiguous observation. But so do millions of other events which we do not classify as suicide. What distinguishes suicide from accidental death is the *intention* of the subject to make an end to his or her life - another theoretical construct which should be rejected outright by any genuine behaviourist.

But things get even worse for the behaviourist interpretation of suicide contagion. The hypothesis which Phillips confirmed is called the "Werther effect". The main observation is that people who were exposed to *stories* of suicide (originally, Goethe's novel "The suffering of the young Werther") are more inclined to commit suicide. Most of the victims of the Werther effect never actually witnessed somebody committing suicide. So, what was replicating was not actual suicidal *behaviour*, but the *idea* that suicide is a good way out of an apparently unsolvable problem. The only way to explain the variety of observations gathered by Phillips is to assume the existence and replication of an unobservable, mental entity: the intention to end one's life.

Of course, as Gatherer might reply, we can never actually observe the replication of the suicide idea. But as I argued earlier, this is a general problem with all scientific concepts. We can merely observe certain indirect effects of the postulated phenomenon, just like astronomers can only observe the presence of a black hole through its effect on nearby matter, not by seeing it directly. Such indirect effects can be misleading, as Gatherer illustrates with his example of the man making Windsor knots for his colleagues: our observations may make us think that these people each know how to make a Windsor knot. But Gatherer is wrong when he concludes from this example that it would be more fruitful to study the replication of the Windsor knot itself, rather than of the ability to make Windsor knots. This is similar to the argument that astronomers should better concern themselves with the study of the light rays that enter their telescopes rather than with the study of stars, galaxies and planets.

Let me suggest an alternative example of a copying machine containing a particular page. The machine may produce 1, 10, 1000, or one million copies of that page. Let us assume that the page contains information that could revolutionize society. For example, it could describe a method to produce unlimited amounts of energy through cold fusion. However, in how far the information on that page will affect the evolution of culture and society does not depend on the actual number of copies that come out of the machine. It depends on whether other people will read that information, whether they will understand it, believe it, communicate it to others, be willing to apply it, etc. These are all mental processes, which are not directly observable. The actual number of physical copies ("artefacts") is irrelevant if those copies are merely stored in a drawer, dropped in a trashbin, or blown away by the wind. It is the cognitive interpretation that determines whether the meme will affect other people's behaviour.

Gatherer also uses his Windsor knot example to argue that the situation in memetics is essentially different from the one in Mendelian genetics. Since one "mnemon" can produce hundred observable instantiations ("phenotypes"), there is no one-to-one relation between memotype and phenotype. But the same problem exists in genetics: one gene can produce dozens of feathers, antlers, branches, leaves or flowers. If you find different pieces of wood, shells or feathers in a geological deposit, you may be misled to think that they were produced by different organisms. In both cases, memetic and genetic, we have to be very careful how we infer the presence of an unobserved, but hypothesized, entity from observable phenomena. Instead of counting the number of Windsor knots, we should better test people on their ability to make a Windsor knot.

This ambiguous correspondence between observed and hypothesized phenomena is a general problem for all scientific modelling, not a specific difficulty for memetics. The problem is particularly acute in psychology, where the hypothesized, "mental" entities tend to be especially complex and variable. This explains why positivism, in the guise of behaviourism, has survived so long in that domain. Yet, by now psychology has developed a wide range of methods to empirically determine the presence of theoretical constructs. The different tests used in personality psychology to assess traits such as intelligence, introversion, dominance, etc. can serve as examples. There is no direct way to observe intelligence. Yet, the scores on different standardized IQ tests provide reliable predictions of a subject's chances for success in other intelligence-related activities, such as academic achievement. The simplest way to explain these

observed regularities is to assume that "intelligence", although a purely mental, unobservable entity objectively exists.

In a similar way, we could devise tests for different memes or features of memes, and then make predictions that people who "have" these memes, as measured by the test, will behave differently from people who score negatively on the test. For example, you could test subjects' knowledge of a hypothetical suicide meme, and then predict that the suicide rate in people with such knowledge will be higher than in those without such knowledge.

The basis of most psychological tests is natural language: you can simply *ask* people whether they consider suicide as an option. Of course, we know that such questions and their answers can be very subjective, and that there are plenty of spurious factors that may influence the results. However, that is insufficient reason to dismiss linguistic communication as a means to detect the presence of memes. A priori rejecting this method simply means rejecting the possibility of any kind of communication or transfer of information via language. And that would mean rejecting the idea that reading and writing papers, the activity we are engaged in at this moment, can contribute to the development of scientific knowledge.

To cope with such problems, psychologists have devised numerous techniques that minimize the subjectivity inherent in asking questions, for example: repeating the same question with different words, asking questions to which the answer is already known in order to test the subject's sincerity, extracting hidden, but reliable patterns from the list of responses, correlating answers to questions with independent observations, etc. All these techniques can be useful for memeticists who wish to operationalize their concept of a meme as a mental entity that influences behaviour.

To conclude my criticism of Gatherer's paper, I would like to ask him why the existing fields of social contagion and diffusion studies, which he holds up as an example of how memetics should develop, have produced so little understanding of cultural evolution. He suggests that this is merely due to an anti-evolutionary prejudice among social psychologists. To me it seems that the problem is more fundamental: it is the behaviourist approach itself which precludes the development of evolutionary models.

Indeed, if the only thing you study is observable behaviour and the way it replicates, then how can you ever account for variation and selection, the basic components of any evolutionary process? Variation in cultural evolution is not normally caused by the copying errors made by a printing press or photocopying machine: it is produced by the people who introduce certain changes in the behaviour they copy. Similarly, behaviours are not generally selected by observable transmission mechanisms such as printing or broadcasting. Behaviours or artefacts are replicated because people for some personal reason consider these behaviours to be worth copying. Thus, we can only get a real understanding of memetic variation and selection if we understand what goes on inside people's head when they listen to a song, read a book, or hear a story.

I have proposed a number of selection criteria that would allow us to predict which memes will survive or be eliminated (Heylighen, 1993, 1997, 1998). These criteria are mostly (though not

exclusively) internal to the person or to the meme. I have also suggested that these criteria, although not directly observable in the behaviourist sense, can be operationalized and empirically tested. That seems to me the way to go if we want to create a real science of memetics: to develop clear theoretical constructs, with a broad explanatory power, which are then operationalized so that they become empirically testable. I agree with Gatherer that many of the theoretical constructs used by memeticists, such as Lynch's (1998) distinction between "belief" and "awareness", are still problematic. But that does not mean that we should stop theorizing. On the contrary, we should reflect more profoundly on what a meme is and how it can be modelled in the most general and yet most precise and concrete way possible.

In conclusion, Gatherer's paper is useful because it reminds us of the importance of operationalization, and the danger of remaining stuck in vagueness and abstraction. However, it is downright misleading in its suggestion that in order to achieve operationalization we should throw out the essential theoretical construct of meme as memory unit, only because it is not directly observable.

STRATEGIES IN MEME THEORY A COMMENTARY ON ROSE'S PAPER: CONTROVERSIES IN MEME THEORY

By

David L. Hull

Department of Philosophy

Evanston, IL 60208

d-hull@nwu.edu

Rose does not care very much for the 'self', in particular the self doing anything, what he terms self-centered selectionism. He finds fault with those who "*believe that consciousness has the power to select memes in order to fulfil some life goal.*" He finds the claim that "*we can intentionally design and choose memes*" is "*entirely at odds with the proposal that culture is an evolutionary process.*"

My immediate response is to ask whether Rose objects to agency and intentionality only in memetic evolution or whether he also objects to it in genetic evolution as well. In most gene-based evolution, intentions and goals play no role in the selection process, but the same can be said for much of meme-based evolution. However, in both gene-based and meme-based evolution, selection in terms of conscious agents doing things for a purpose at least seems to play a role. Rose limits his discussion to meme-based evolution, but the problem arises just as seriously in gene-based evolution.

Darwin began his 'Origin of Specise' with a long discussion of artificial selection. In Darwin's day and before, plant and animal breeders selected "sports" that they found useful and bred them selectively so that these variations became more common; e.g., ancon sheep. Darwin reasoned that if breeders could do so much with so little, one can only imagine how powerful natural selection must be. Apparently, Rose rejects Darwin's argument because the goals of conscious agents play a crucial role in artificial selection. Breeders did not produce the variations, but they did select them. Nowadays, breeders are in even a stronger position. They can also design the variations that they want. They can intentionally design and choose genes. Is artificial selection an "*unnatural*" process? Can it be explained without reference to selves, goals and intentions?

Rose seems to think that intentional behavior is Lamarckian if not downright miraculous. I think that it is neither. Even so, I agree with Rose that including it in theories of genetic or memetic evolution right now is a bad strategy because it introduces whole series of issues that are currently highly problematic. Perhaps someday in the future we can handle the roles that conscious agents play in both sorts of evolution, but not right now. The strategy that I am suggesting is the same one adopted by evolutionary biologists with respect to development. In Darwin's day, development looked promising. Some of the biggest names in science were working on it, but at the time evolutionary biologists could not find a way to integrate these findings in their theory. Instead, they worked their way around development, not to mention genetics. Their contemporaries were happy to point out the 'holes' in their theoretical structure, but the Darwinians could do nothing, until, finally, at the turn of the century, a theory of heredity

was formulated that (after some overly obtuse wrangling) fit nicely into evolutionary theory. We are still waiting for development. But right now things look promising!

Those of us working in memetics need not deride the self, agents, goals, intentions, and the like. Someday we may be able to work them into our theory, but not now. What is lost if we do restrict our attention? How important are intentions in organisms other than human beings? Organisms do strive to get away from predators as these predators strive to capture them. It is difficult not to see these phenomena in terms of goals. But even plants exhibit tropisms. They seem to strive toward sunlight and the like. But one thing that these organisms do not do is strive to evolve. Now, can all this 'striving' be interpreted solely in behaviorist terms? The history of behavioral psychology is spotty. Behavioral psychologists have made significant headway in their program, but even with respect to nonhuman animals, problems remain. However, I think that the safest bet, for now, is to adopt a behaviorist view of organisms other than humans. Little is lost, and quite a bit is gained. One might mention that operant learning is itself a selection process (Skinner 1974 and Glenn 1991).

When the issue is humans, the vast majority of people, scientists included, reject a purely behavioral account of behavior. We are conscious. We do have goals, and we do strive to realize these goals. I happen to be a bit cynical about human beings, me included. I think that a huge chunk of our behavior can be explained in purely behavioral terms without significant loss. For example, we constantly hear about all the damage that the human species is doing to the environment. I hasten to add that almost none of this degradation was intentional. We didn't mean to do it. To make matters worse, the vast majority of human beings have never heard of biological evolution. Of those who have, most do not understand it very well, and even fewer accept it. Only a very tiny percentage of the human race understands biological evolution and believes it. This small minority is in a position to introduce their intentions and goals into the evolutionary process. I shudder to think of the effects. In the past most of the modifications that we have consciously made in the environment on the basis of the best knowledge at the time did not turn out the way that we expected. It is still possible for people who understand evolutionary biology to produce the effects that they intend, but these effects are likely to be quite minor when compared to all the unconscious effects. If our intentions matter so little with respect to such phenomena, I fail to see why we have to mention them, except to dismiss them.

Perhaps the human race does not have a very good track record with respect to such huge phenomena, but how about other areas of human endeavor? On a day-to-day time scale, people behave intentionally. We get hungry and go to the local Wends to get a hamburger. Is there anything so wrong in saying as much? Most of our behavior can be explained entirely in behaviorist terms, but a substantial amount remains. Behavioral psychologists no longer claim that they can explain all human behavior in terms of operant conditioning, even of the most sophisticated sort. Maybe, some time in the future, they will be able to explain more, but all? That is highly questionable, especially when one turns to science itself. Science is as intentional a process as has ever appeared on Earth. When Rose urges that we reject references to 'selves', 'intentions', 'purposes', etc. in memetic evolution, is he not doing so for a purpose? He does not intend for us to change our focus of research? But all of this is just so much everyday talk. Once psychology gets sufficiently powerful, we can explain human behavior without reference, no matter how covert, to the entities and processes that Rose finds so objectionable. Perhaps so, but

I suggest a more cautious strategy. Just as evolutionary biologists have waited for the science of development to catch up before they attempted to incorporate it into evolutionary biology, I suggest that we memeticists exhibit similar caution in committing ourselves so totally with respect to a behaviorist stance for all of human behavior. Behavioral psychology is sufficiently well developed that we can use it and only it for the behavior of all other creatures without significant loss, but when we turn to us, I think that behavioral psychology is not currently up to the task. Let's hold these issues off to the side while we attack those problems that seem more soluble. Attacking the Big Issue right now and failing is certainly designed to harm our emerging research program. (OK, OK, maybe we are not doing it on purpose, but I suggest that it is the most likely result.)

To return to the opening paragraphs of this note, if Rose wants to make memetics as pure as he thinks it should be, then he must reject artificial selection as so much magic. To be sure in artificial selection the replicators are genes and not memes, but the selection process itself is riddled with intentional, goal-directed behavior, and we are currently in no position to eliminate reference to this behavior because we currently have nothing to put in its place. But if Rose's position is put in slightly different terms, I am all in favor of it. Because of all the problems surrounding 'selves' behaving 'intentionally' to fulfil 'goals', for now at least let's ignore it and continue to work on the vast majority of behavior in which such considerations do not arise.

Right now we have only scratched the surface with respect to these much less problematic phenomena. Once we get really good at handling them, then we can turn to the hardest parts. One of the faults that I find with philosophers is that we attack the big issues first. Scientists have had the good sense to attack at least some of the more soluble problems early on. As Medawar (1967) put it, science is the art of the soluble.

BRIDGING THE GAP: MEMETICS AS A METHODOLOGICAL TOOL TO CLOSE THE RANKS BETWEEN SOCIAL AND TRADITIONAL HISTORY

**By
Rogan Jacobson**

This paper will look at the evolutionary nature of information replication and transfer, and to use memetics as a methodological tool for historical analysis, and one which helps to rebuild the gap between traditional and sociological historical methods. Traditionally, modern scholars write histories using contemporary texts and analyzing them through the window of hindsight, causality and comparison to surrounding texts; social historians use various methods of analysis to contextualize the information and plot or map the surrounding action, yet these largely treat the content of the text as being of primary importance, more often than not leaving unassessed the structure of the information presentation.

Memetic science is in its infancy, and is currently being used in many and varied academic and non-academic fields; such as the work of Richard Dawkins in the field of evolutionary biology, Daniel Dennett in his research on the philosophy of mind, others in the fields of social sciences such as Francis Heylighen, and a host of others in such diverse fields as artificial intelligence research, corporate strategy planning, psychology, sociology and cultural evolution. However, to the best of my knowledge memetics has not as yet been used extensively in the study of history. This is probably fairly easily explained. The science itself is, as I said, in its infancy. Therefore, a great deal of time and effort is currently being spent upon the method itself, seeking a more rigid analytical framework. These issues and many more are currently being fleshed out by memeticists, or interested academics, all over the globe. However, it cannot be denied that memetics does have something to offer us now, even in its youth, as an explanation of thought by analyzing the structures by which 'successful' or popular ideas transmit themselves from brain to brain. The science offers us the ability to structurally assign properties to certain types of ideas, empirically defend this formula, and then assess what this 'idea', this meme, can be expected to do or more importantly not do. For the historian working with, at best, often shaky accounts of actual events, and more often than not simply working with accounts expressing various successful ideas of the day, this science may prove invaluable.

Memetics can be used by the historian of ideas (from either camp) to determine the nature of any historical information transfer structure by mapping, as it were, the way in which the data propagates and the structural information/belief issues comprising the 'meme pool' of the time being investigated, thereby adding color to the historian's analysis and providing a fuller history.

To provide scope for an explication of memetics as methodology, albeit in its infancy, and as an academic discipline in its own right, I shall be looking specifically at the field of ancient religious history in the time of St Augustine. Ancient religious history, more so than more modern or contemporary history, suffers in research from a dearth of texts (due largely to lesser technologies and lower literacy rates) leaving traditional historians often forced to lean towards 'best guess' invention to complete a textual picture of the times. In cases where texts simply weren't written, and oral histories have been lost, historians are often faced with massive linear

breaks in their analysis, and resort to economic or geographical considerations to fill in the blanks. This concentration on the content of texts and the actions of contemporary actors, and not the structural nature of the information replication itself, presents a problem in modern historiography that memetic analysis should be used to redress.

In determining an interpretation of events, it is often practiced procedure for traditional historians to try and bleed their sources of the input of the author, to remove any personal, subjective comments in the interest of a Dagnet 'just the facts ma'am' objectivity. This history of 'heroes and monsters' is slowly being subsumed by social historical theory [1], such as that proposed by Roland Barthes in his essay on 'Historical Discourse'. Barthes argues that this practice of analysis is detrimental to the history itself. The historian, in writing, tries to remove his/her own persona from the work, to give the impression that we have before us nothing but statistical data. This attempt is seen by the structuralists as semantically impossible, given that not only must the historian interpret the data, but he/she must then write a history within the linguistic terms of his/her own contemporary society, their *langue*, and under the code-restrictions of their day.[2] . Traditional historians try to argue that the referent is speaking for itself, ontologically privileging the historical fact above and beyond the signs which make it known [3].

The sociological historians, however, approach the information in a radically different way. Structuralist history theories, such as those put forward by historians and social theorists such as Michel Foucault, stress that the analysis of historical texts, or our information packages, should look less toward the content of texts, and more toward the signification to be found concerning the wider society located therein, looking for ideological ciphers to extrapolate the world view surrounding them. As Foucault notes, the role of the 'new' history is not to interpret the document; instead it "organizes the document, divides it up, distributes it, orders, arranges it in levels, establishes series, distinguishes between what is relevant and what is not, discovers, elements, defines unities, describes relations"[4]. Both types of history have evolved towards each other, with traditional historians often using sociological method in their analysis[5], yet leaving the pragmatic 'traditional' assessment of replication mechanisms untouched. In the case of St Augustine we see a prime example of this. In his lifetime, Augustine of Hippo was a prolific writer, seeking to promote a specific type of church and propagation of Christianity, namely one heavily steeped in the realities of the world around it, and one keen to acquire power and unity. This message, most clearly outlined textually in his work *De Doctrina Christiana*, centers around notions of education in Christian discourse and philosophical involvement with pagan writings and arguments as opposed to the discord among believers which arises when dealing with conflicting beliefs. "Nay, but let every good and true Christian understand that wherever truth may be found, it belongs to his Master; and while he recognizes and acknowledges the truth, even in their religious literature, let him reject the figments of superstition... And even when in the course of an historical narrative former institutions of men are described, the history itself is not to be reckoned among human institutions; because things that are past and gone and cannot be undone are to be reckoned as belonging to the course of time, of which God is the author and governor." [6].

Traditional historical analysis treats the text of the document as sacred, seeking objectivity in analysis by determining from the text the nature of the author's ideas on the structure of the church as a focal point for the changing nature of early church history. Structuralist approaches

use the text to depart from it to the audience and divine the nature of the society around St Augustine, arriving at assumptions about education, and learning etc. Both methods come together well, yet neither addresses the mechanical reasons behind the replication of such a text.

Memetic fitness criteria

Memetic analysis proposes certain criteria for the survival and successful replication of an idea, any idea, without references to the empirical or theoretical 'truth' of the content. In this sense, memetics offers the researcher into the history of ideas an analytical tool for looking at text without fear of being subjectively swayed by the actual content of the texts being studied. The criteria by which memes are deemed fit or unfit in terms of their ability to replicate centre essentially, as noted by Dawkins [7], around their fecundity, copying fidelity and longevity. The analysis of these criteria provides a structural blueprint for the historian in that they allow a reassessment of texts in terms of the cultural structure, or meme pool, in which they are found to replicate.

The fecundity of any meme, i.e. its ability to be understood, presents many interesting possibilities for the historian. *De Doctrina Christiana*, for example, has been treated by modern scholars largely in light of its similarity to modern semiotic theory. The text is being treated and analyzed in terms of the effect such theories have had on modern intellectual discourse. However, by looking at the ability of contemporary sources to understand basic sign-theory, we see a smaller pool of possible replication. Such theories previously only existed in rhetorical schools of Greece and Rome, and held little sway over the general populous. To this end, we see St Augustine increasing the fecundity of the work by adding references and analyses that would easily be understood by a wider audience - music, the games, pagan epics and myths etc. Thus the historian is able to see, before analyzing the content, that the meme of the work is a fit one for the surrounding meme pool and ought to do well.

The copying fidelity of any meme can also be measured a great degree of accuracy. Again, our example of *De Doctrina Christiana* would replicate well. It consists of short paragraphs, easily sent in letter form, or read out in sermons. It refers directly to, and quotes heavily from, Scriptures which were already circulated and can be written or spoken at academic or basic levels of intellectual understanding.

And finally, the longevity of the work shows the historian how likely the meme is to propagate. In *De Doctrina Christiana*, we see a work which although specific in its reference to biblical texts (already strong memes, and already shown to be long-lived) other contemporary references are kept at a minimum and metaphor is brought into play. In this way the work is able to achieve an intellectually 'timeless' quality, which enables it to persist and replicate long after references to local conditions have passed from memory.

Fitness criteria can easily be adjusted constantly according to information on the available means of replication. That is to say, for example, a meme in fourth century Europe would not necessarily be deemed unfit for its inability to transfer well on television. All that is required for an idea to be treated as a meme is that it should behave like one; ie that it should be highly successful in replicating itself within a given community. Further and more specific memetic

conditions for replication fitness are contained in the handout of the work by Ron Hale-Evans[8]. These criteria, more specific in their inquiry, provide the historian a blueprint, as it were, for the strength of any meme in a given society, and a base from which to embark upon other methodologies of analysis. In terms of cultural evolution, therefore, the researcher is able to generate a blueprint of the meme pool of the day by looking at means of information dispensation and replication and the mechanisms by which the more successful memes of the time propagate; historians of any period can usually pinpoint, with a fair degree of accuracy, such factors as influence the replication of ideas:

- languages spoken, and who understood them,
- state of literacy
- most common means of general populous communication
- technological means of the society
- interaction with other surrounding societies and ease of transfer between them

For example, we are able to see that in 4th century Europe oral histories delivered in terms of narrative, sermon and parable, philosophical debate, letter writing and book production were the key machinery for the replication of ideas concerning the early church. Memetic analysis of these mechanisms, determining who had access to them and how they were used, provides the historian with a clear view of possible successful memes in terms of structure.

What's in a meme: increased objectivity in historical analysis

Memes replicate without any overt responsibility for the nature of their content. For the historian this provides a clean arena for analysis; it cannot be argued that the meme of Christianity was passed on and replicated itself successfully in its chosen form because it was right, or because it was true, but merely because over the period of its birth and growth, the form in which the meme survived was the most successfully copied, more easily able to reach 'uninfected minds' (for reasons open to discussion) and more able to meld with the other beliefs stored in the mind of the follower. The structure of the information package was, and indeed still is, a memetically fit one.

A meme that successfully replicates itself is not necessarily *good* or *right*; rather it merely operates more effectively within the cultural climate it finds itself. We see then that St Augustine's meme of Christianity was able to replicate itself more frequently, among more minds and across more generations while maintaining a high degree of copying fidelity than the other religious memes competing with Christianity at the time. One meme supplanted the other for the predominant mind-space, yet both 'survived'. Memetics is a useful method for the historian seeking to paint a picture of a contemporary meme-pool in concert with more traditional assessments of ancient European culture, which as often as not take into account at a paramount level; such things as the local geography, ideological voids left with the passing of the strength of the Roman Empire, military issues concerning the 'friendship' of the Church with the emperor, the nature of the religion in a historical sense, perceived religious voids and other such issues. In other words, historians of the period can use memetics to look at the replication of two complementary and competing ideas of Christianity, not merely at paganism and Christianity. Further, memetic methodology can be used to more effectively assess the effect of the actions of the individuals who hold and replicate these ideas upon the replication and mutation of that idea

throughout the meme pool. Normal methods of historical inquiry, whether social or traditional, are inadequate in this field, as they concentrate too heavily upon the actions of the 'agents', and not enough upon the structure and force of the ideas themselves.

This brings us to an interesting criticism of memetic method, namely the nature and relevance of truth claims. Memetic historical methodology involves investigating what can be referred to as the mechanisms for a 'successful idea', and yet in the case of religion it happens to be an idea (or more correctly a complex series of ideas) which is packed to the rafters with truth statements. It may therefore be argued that since this particular idea (or indeed any other successful meme) most aptly succeeds in the human cultural sphere, it lends itself to notions of truth. This, however, is not a function of the science. All we are researching here is the strength (replicating ability/attractiveness/copying fidelity) of an idea, and how one meme can supplant another in the minds of believers, an area which in no way suggests that in our case Augustine was 'right', and orthodox pagan religions 'wrong', but does imply that Augustine's ideas were memetically strong in their phrasing and reproduction, giving them a far better chance of replication in the society of the time.

Memetic theory in history is a methodology for the assessment of the replication possibilities of ideas, not their 'truth'. We could just as easily use memetics to assess the 'flat earth theory' (still alive today in some ever decreasing circles) without ever mentioning the 'truth' of its claims. The only 'truth' claimed by the science is a mechanical one. That is, the prevalence and success of certain ideas to reach more people can be traced to certain memetics structural imperatives, and the growth of such ideas more accurately charted. Most methods of analysis when charting or explaining the growth and history of ideas have relied upon their perceived effect upon the 'readership', and their historical relationship to what has gone before. Memetics, however, provides a more objective standpoint. With it we can look at the replication of an idea in itself, then go on to attribute this idea with certain proactive 'abilities', or avenues for replication and spread. This, more fully explained and researched idea will then be submitted to regular methods of analysis, but from all sides. The language will come under scrutiny, also the subject matter, the changes in audience, the perspective of the writer, the perceived world-view of the laity and the goal of the work. This, I believe, will give us a new direction to ponder in terms of historical research and analysis.

GREAT MEN, GREAT THOUGHTS, AND THE ENVIRONMENT

By

William James

Lecture delivered before the Harvard Natural History Society.

Published in the *Atlantic Monthly*, October, 1880

A remarkable parallel, which I think has never been noticed, obtains between the facts of social evolution on the one hand, and of zoological evolution as expounded by Mr. Darwin on the other.

It will be best to prepare the ground for my thesis by a few very general remarks on the method of getting at scientific truth. It is a common platitude that a complete acquaintance with any one thing, however small, would require a knowledge of the entire universe. Not a sparrow falls to the ground but some of the remote conditions of his fall are to be found in the Milky Way, in our federal constitution, or in the early history of Europe. That is to say, alter the Milky Way, alter our federal constitution, alter the facts of our barbarian ancestry, and the universe would so far be a different universe from what it now is. One fact involved in the difference might be that the particular little street-boy who threw the stone which brought down the sparrow might not find himself opposite the sparrow at that particular moment; or, finding himself there, he might not be in that particular serene and disengaged mood of mind which expressed itself in throwing the stone. But, true as all this is, it would be very foolish for anyone who was inquiring the cause of the sparrow's fall to overlook the boy as too personal, proximate, and so to speak anthropomorphic an agent, and to say that the true cause is the federal constitution, the westward migration of the Celtic race, or the structure of the milky way. If we proceeded on that method, we might say with perfect legitimacy that a friend of ours, who had slipped on the ice upon his door-step and cracked his skull, some months after dining with thirteen at the table, died because of that ominous feast. I know, in fact, one such instance; and I might, if I chose, contend with perfect logical propriety that the slip on the ice was no real accident. "There are no accidents," I might say, "for science. The whole history of the world converged to produce that slip. If anything had been left out, the slip would not have occurred just there and then. To say it would is to deny the relations of cause and effect throughout the universe. The real cause of the death was not the slip, *but the conditions which engendered the slip*, -- and among them his having sat at a table, six months previous, one among thirteen. *That* is truly the reason why he died within the year."

It will soon be seen whose arguments I am, in form, reproducing here. I would fain lay down the truth without polemics or recrimination. But unfortunately we never fully grasp the import of any true statement until we have a clear notion of what the opposite untrue statement would be. The error is needed to set off the truth, much as a dark background is required for exhibiting the brightness of a picture. And the error which I am going to use as a foil to set off what seems to me the truth of my own statements is contained in the philosophy of Mr. Herbert Spencer and his disciples. Our problem is: What are the causes that make communities change from generation to generation, - that make the England of Queen Anne so different from the England of Elizabeth, the Harvard College of to-day so different from that of thirty years ago?

I shall reply to this problem: The difference is due to the accumulated influences of individuals, of their examples, their initiatives, and their decisions. The Spenserian school replies: The changes are irrespective of persons, and independent of individual control. They are due to the environment, to the circumstances, the physical geography, the ancestral conditions, the increasing experience of our relations; to everything, in fact, except the Grants and the Bismarcks, the Joneses and the Smiths.

Now, I say that these theorizers are guilty of precisely the same fallacy as he who should ascribe the death of his friend to the dinner with thirteen, or the fall of the sparrow to the Milky Way. Like the dog in the fable, who drops his real bone to snatch at its image, they drop the real causes to snatch at others, which from no possible human point of view are available or attainable. Their fallacy is a practical one. Let us see where it lies. Although I believe in free-will myself, I will waive that belief in this discussion, and assume with the Spenserians the predestination of all human actions. On that assumption I gladly allow that were the intelligence investigating the man's or the sparrow's death omniscient and omnipresent, able to take in the whole of time and space at a single glance, there would not be the slightest objection to the milky way or the fatal feast being invoked among the sought-for causes. Such a divine intelligence would see instantaneously all the infinite lines of convergence towards a given result, and it would, moreover, see impartially: it would see the fatal feast to be as much a condition of the sparrow's death as of the man's; it would see the boy with the stone to be as much a condition of the man's fall as of the sparrow's.

The human mind, however, is constituted on an entirely different plan. It has no such power of universal intuition. Its finiteness obliges it to see but two or three things at a time. If it wishes to take wider sweeps it has to use 'general ideas,' as they are called, and in so doing to drop all concrete truths. Thus, in the present case, if we as men wish to feel the connection between the Milky Way and the boy and the dinner and the sparrow and the man's death, we can do so only by falling back on the enormous emptiness of what is called an abstract proposition. We must say: All things in the world are fatally predetermined, and hang together in the adamantine fixity of a system of natural law. But in the vagueness of this vast proposition we have lost all the concrete facts and links; and in all practical matters the concrete links are the only things of importance. The human mind is essentially partial. It can be efficient at all only by *picking out* what to attend to, and ignoring everything else, - by narrowing its point of view. Otherwise, what little strength it has is dispersed, and it loses its way altogether. Man always wants his curiosity gratified for a particular purpose. If, in the case of the sparrow, the purpose is punishment, it would be idiotic to wander off from the cats, boys, and other possible agencies close by in the street, to survey the early Celts and the Milky Way: the boy would meanwhile escape. And if, in the case of the unfortunate man, we lose ourselves in contemplation of the thirteen-at-table mystery, and fail to notice the ice on the step and cover it with ashes, some other poor fellow, who never dined out in his life, many slip on it in coming to the door, and fall and break his head too.

It is, then, a necessity laid upon us as human beings to limit our view. In mathematics we know how this method of ignoring and neglecting quantities lying outside a certain range has been adopted in the differential calculus. The calculator throws out all the "infinitesimals of the quantities he is considering. He treats them (under certain rules) as if they did not exist. In

themselves they exist perfectly all the while; but they are as if they did not exist for the purposes of his calculation. Just so an astronomer, dealing with the tidal movements of the ocean, takes no account of the waves made by the wind, or by the pressure of all the steamers which day upon night are moving their thousands of tons upon its surface. Just so the marksman, in sighting his rifle, allows for the motion of the wind, but not for the equally real motion of the earth and solar system. Just so a business man's punctuality may overlook an error of five minutes, while a physicist, measuring the velocity of light, must count each thousandth of a second.

There are, in short, *different cycles of operation* in nature; different departments, so to speak, relatively independent of one another, so that what goes on at any moment in one may be compatible with almost any condition of things at the same moment in the next. The mould on the biscuit in the store-room of a man-of-war vegetates in absolute indifference to the nationality of the flag, the direction of the voyage, the weather, and the human dramas that may go on onboard; and a mycologist may study it in complete abstraction from all these larger details. Only by so studying it, in fact, is there any chance of the mental concentration by which alone he may hope to learn something of its nature. On the other hand, the captain, who in maneuvering the vessel through a naval fight, should think it necessary to bring the moldy biscuit into his calculations, would very likely lose the battle by reason of the excessive "thoroughness" of his mind.

The causes which operate in these incommensurable cycles are connected with one another only *if we take the whole universe into account*. For all lesser points of view it is lawful - nay, more, it is for human wisdom necessary - to regard them as disconnected and irrelevant to one another.

And this brings us nearer to our special topic. If we look at an animal or a human being, distinguished from the rest of his kind by the possession of some extraordinary peculiarity, good or bad, we shall be able to discriminate between the causes which originally *produced* the peculiarity in him and the causes that *maintained* it after it is produced; and we shall see, if the peculiarity be one that he was born with, that these two sets of causes belong to two such irrelevant cycles. It was the triumphant originality of Darwin to see this, and to act accordingly. Separating the causes of production under the title of 'tendencies to spontaneous variation,' and relegating them to a physiological cycles which he forthwith agreed to ignore altogether, he confined his attention to the causes of preservation, and under the names of natural selection and sexual selection studied them exclusively as functions of the cycle of the environment.

Pre-Darwinian philosophers had also tried to establish the doctrine of descent with modification; but they all committed the blunder of clumping the two cycles of causation into one. What preserves an animal with his peculiarity, if it be a useful one, they saw to be the nature of the environment to which the peculiarity was adjusted. The giraffe with his peculiar neck is preserved by the fact that there are, in his environment, tall trees whose leaves he can digest. But these philosophers went further, and said that the presence of the trees not only maintained an animal with a long neck to browse upon their branches, but also produced him. They *made* his neck long by the constant striving they aroused in him to reach up to them. The environment, in short, was supposed by these writers to mould the animal by a kind of direct pressure, very much as a seal presses the wax into harmony with itself. Numerous instances were given of the way in which this goes on under our eyes. The exercise of the forge makes the right arm strong, the

palm grows callous to the oar, the mountain air distends the chest, the chased fox grows cunning and the chased bird shy, the arctic cold stimulates the animal combustion, and so forth. Now these changes, of which many more examples might be adduced, are at present distinguished by the special name of *adaptive* changes. Their peculiarity is that that very feature in the environment to which the animal's nature grows adjusted, itself produces the adjustment. The 'inner relation,' to use Mr. Spencer's phrase, 'corresponds' with its own efficient cause.

Darwin's first achievement was to show the utter insignificance in amount of these changes produced by direct adaptation, the immensely greater mass of changes being produced by internal molecular accidents, of which we know nothing. His next achievement was to define the true problem with which we have to deal when we study the effects of the visible environment on the animal. That problem is simply this: Is the environment more likely to *preserve or to destroy him*, on account of this or that peculiarity with which he may be born? In giving the name of "accidental variations" to those peculiarities with which an animal is born, Darwin does not for a moment mean to suggest that they are not the fixed outcome of natural law. If the total system of the universe be taken into account, the causes of these variations and the visible environment which preserves or destroys them, undoubtedly do, in some remote and round-about way, hang together. What Darwin means is, that, since the environment is a perfectly known thing, and its relations to the organism in the way of destruction or preservation are tangible and distinct, it would utterly confuse our finite understandings and frustrate our hopes of science to mix in with it facts from such a disparate and incommensurable cycle as that in which the variations are produced. This last cycle is that of occurrences before the animal is born. It is the cycle of influences upon ova and embryos; in which lie the causes that tip them and tilt them towards masculinity or femininity, towards strength or weakness, towards health or disease, and towards divergence from the parent type. What are the causes there?

In the first place, they are molecular and invisible, - inaccessible, therefore, to direct observation of any kind. Secondly, their operations are compatible with any social, political and physical conditions of the environment. The same parents, living in the same environing conditions, may at one birth produce a genius, at the next an idiot or a monster. The visible external conditions are therefore not direct determinants of this cycle; and the more we consider the matter, the more we are forced to believe that two children of the same parents are made to differ from each other by causes as disproportionate to their ultimate effects as is that famous pebble on the Rocky Mountain crest, which separates two rain-drops, to the Gulf of St. Lawrence and the Pacific Ocean towards which it makes them severally flow.

The great mechanical distinction between transitive forces and discharging forces is nowhere illustrated on such a scale as in physiology. Almost all causes there are forces of *detent*, which operate by simply unlocking energy already stored up. They are upsetters of unstable equilibria, and the resultant effect depends infinitely more on the nature of the materials upset than on that of the particular stimulus which joggles them down. Galvanic work, equal to unity, done on a frog's nerve will discharge from the muscle to which the nerve belongs mechanical work equal to seventy thousand; and exactly the same muscular effect will emerge if other irritants than galvanism are employed. The irritant has merely started or provoked something which then went on of itself, - as a match may start a fire which consumes a whole town. And qualitatively as well as quantitatively the effect may be absolutely incommensurable with the cause. We find this

condition of things in all organic matter. Chemists are distracted by the difficulties which the instability of albuminoid compounds opposes to their study. Two specimens, treated in what outwardly seem scrupulously identical conditions, behave in quite different ways. You know about the invisible factors of fermentation, and how the fate of a jar of milk - whether it turn into a sour clot or a mass of koumiss - depends on whether the lactic acid ferment or the alcoholic is introduced first, and gets ahead of the other in starting the process. Now, when the result is the tendency of an ovum, itself invisible to the naked eye, to tip towards this direction or that in its further evolution, - to bring forth a genius or a dunce, even as the rain-drop passes east or west of the pebble, - is it not obvious that the deflecting cause must lie in a region so recondite and minute, must be such a ferment of a ferment, an infinitesimal of so high an order, that surmise itself may never succeed even in attempting to frame an image of it?

Such being the case, was not Darwin right to turn his back upon that region altogether, and to keep his own problem carefully free from all entanglement with matters such as these? The success of his work is a sufficient affirmative reply.

And this brings us at last to the heart of our subject. The causes of production of great men lie in a sphere wholly inaccessible to the social philosopher. He must simply accept geniuses as data, just as Darwin accepts his spontaneous variations. For him, as for Darwin, the only problem is, these data being given: How does the environment affect them, and how do they affect the environment? Now, I affirm that the relation of the visible environment to the great man is in the main exactly what it is to the "variation" in the Darwinian philosophy. It chiefly adopts or rejects, preserves or destroys, in short *selects* him. And whenever it adopts and preserves the great man, it becomes modified by his influence in an entirely original and peculiar way. He acts as a ferment and changes its constitution, just as the advent of a new zoological species changes the faunal and floral equilibrium of the region in which it appears. We all recollect Mr. Darwin's famous statement of the influence of cats on the growth of clover in their neighborhood. We all have read of the effects of the European rabbit in New Zealand, and we have many of us taken part in the controversy about the English sparrow here, - whether he kills more canker worms, or drives away most native birds. Just so the great man, whether he be an import from without like Clive in India or Agassiz here, or whether he spring from the soil like Mahomet or Franklin, brings about a rearrangement, on a large or a small scale, of the pre-existing social relations.

The mutations of societies, then, from generation to generation, are in the main due directly or indirectly to the acts or the examples of individuals whose genius was so adapted to the receptivities of the moment, or whose accidental position of authority was so critical that they became ferments, initiators of movements, setters of precedent or fashion, centers of corruption, or destroyers of other persons, whose gifts, had they had free play, would have led society in another direction.

We see this power of individual initiative exemplified on a small scale all about us, and on a large scale in the case of the leaders of history. It is only following the common-sense method of a Lyell, a Darwin and a Whitney to interpret the unknown by the known, and reckon up cumulatively the only causes of social change we can directly observe. Societies of men are just like individuals, in that both at any given moment offer ambiguous potentialities of development. Whether a young man enters business or the ministry may depend on a decision which has to be

made before a certain day. He takes the place offered in the counting-house, and is *committed*. Little by little, the habits, the knowledge of the other career, which once lay so near, cease to be reckoned even among his possibilities. At first, he may sometimes doubt whether the self he murdered in that decisive hour might not have been the better of the two; but with the years such questions themselves expire, and the old alternative *ego*, once so vivid, fades into something less substantial than a dream. It is no otherwise with nations. They may be committed by kings and ministers to peace or war, by generals to victory or defeat, by prophets to this religion or that, by various geniuses to fame in art, science or industry. A war is a true point of bifurcation of future possibilities. Whether it fail or succeed, its declaration must be the starting-point of new policies. Just so does a revolution, or any great civic precedent, become a deflecting influence, whose operations widen with the course of time. Communities obey their ideals; and an accidental success fixes an ideal, as an accidental failure blights it.

Would England have to-day the "imperial" ideal which she now has, if a certain boy named Bob Clive had shot himself, as he tried to do, at Madras? Would she be the drifting raft she is now in European affairs if a Frederic the Great had inherited her throne instead of a Victoria, and if Messrs. Bentham, Mill, Cobden, and Bright had all been born in Prussia? England has, no doubt, to-day precisely the same intrinsic value relatively to the other nations that she ever had. There is no such fine accumulation of human material upon the globe. But in England the material has lost effective form, while in Germany it has found it. Leaders give the form. Would England be crying forward and backward at once, as she does now, "letting I will not wait upon I would," wishing to conquer but not to fight, if her ideal had in all these years been fixed by a succession of statesmen of supremely commanding personality, working in one direction? Certainly not. She would have espoused, for better or worse, either one course or another. Had Bismarck died in his cradle, the Germans would still be satisfied with appearing to themselves as a race of spectacled *Gelehrten* and political herbivora, and to the French as *ces bons*, or *ces naifs*, *Allemands*. Bismarck's will showed them, to their own great astonishment, that they could play a far livelier game. The lesson will not be forgotten. Germany may have many vicissitudes, but they –

*"will never do away, I ween
The marks of that which once hath been" -*

of Bismarck's initiative, namely, from 1860 to 1873.

The fermentative influence of geniuses must be admitted as, at any rate, one factor in the changes that constitute social evolution. The community *may* evolve in many ways. The accidental presence of this or that ferment decides in which way it *shall* evolve. Why, the very birds of the forest, the parrot, the mino, have the power of human speech, but never develop it of themselves; someone must be there to teach them. So with us individuals. Rembrandt must teach us to enjoy the struggle of light with darkness, Wagner to enjoy peculiar musical effects; Dickens gives a twist to our sentimentality, Artemus Ward to our humor; Emerson kindles a new moral light within us. But it is like Columbus's egg. "All can raise the flowers now, for all have got the seed." But if this be true of individuals in the community, how can it be false of the community as a whole? If shown a certain way, a community may take it; if not, it will never find it. And the ways are to a large extent indeterminate in advance. A nation may obey either of many

alternative impulses given by different men of genius, and still live and be prosperous, just as a man may enter either of many businesses. Only, the prosperities may differ in their type. But the indeterminism is not absolute. Not every "man" fits every "hour." Some incompatibilities there are. A given genius may come either too early or too late. Peter the Hermit would now be sent to an insane asylum. John Mill in the tenth century would have lived and died unknown. Cromwell and Napoleon need their revolutions, Grant his civil war. An Ajax gets no fame in the day of telescopic-sighted rifles; and, to express differently an instance which Spencer uses, what could a Watt have affected in a tribe which no precursive genius had taught to smelt iron or to turn a lathe?

Now, the important thing to notice is that what makes a certain genius now incompatible with his surroundings is usually the fact that some previous genius of a different strain has warped the community away from the sphere of his possible effectiveness. After Voltaire, now Peter the hermit; after Charles IX and Louis XIV, no general protestantization of France; after a Manchester school, a Beaconsfield's success is transient; after a Philip II, a Castelar makes little headway; and so on. Each bifurcation cuts off certain sides of the field altogether, and limits the future possible angles of deflection. A community is a living thing, and in words which I can do no better than quote from Professor Clifford, "it is the peculiarity of living things not merely that they change under the influence of surrounding circumstances, but that any change which takes place in them is not lost but retained, and as it were built into the organism to serve as the foundation for future actions. If you cause any distortion in the growth of a tree and make it crooked, whatever you may do afterwards to make the tree straight the mark of your distortion is there; it is absolutely indelible; it has become part of the tree's nature. ... Suppose, however, that you take a lump of gold, melt it, and let it cool. ... No one can tell by examining a piece of gold how often it has melted and cooled in geologic ages, or even in the last year by the hand of man. Anyone who cuts down an oak can tell by the rings of its trunk how many times winter has frozen it into widowhood, and how many times summer has warmed it into life. A living being must always contain within itself the history, not merely of its own existence, but of all its ancestors."

Every painter can tell us how each added line deflects his picture in a certain sense. Whatever lines follow must be built on those first laid down. Every author who starts to rewrite a piece of work knows how impossible it becomes to use any of the first-written pages again. The new beginning has already excluded the possibility of those earlier phrases and transitions, while it has at the same time created the possibility of an indefinite set of new ones, no one of which, however, is completely determined in advance. Just so the social surroundings of the past and present hour exclude the possibility of accepting certain contributions from individuals; but they do not positively define what contributions shall be accepted, for in themselves they are powerless to fix what the nature of the individual offerings shall be.

Thus social evolution is a resultant of the interaction of two wholly distinct factors, - the individual, deriving his peculiar gifts from the play of physiological and infra-social forces, but bearing all the power of initiative and origination in his hands; and, second, the social environment, with its power of adopting or rejecting both him and his gifts. Both factors are essential to change. The community stagnates without the impulse of the individual. The impulse dies away without the sympathy of the community.

All this seems nothing more than common-sense. All who wish to see it developed by a man of genius should read that golden little work, Bagehot's *Physics and Politics*, in which (it seems to me) the complete sense of the way in which concrete things grow and change is as livingly present as the straining after a pseudo-philosophy of evolution is livingly absent. But there are never-wanting minds to whom such views seem personal and contracted, and allied to an anthropomorphism long exploded in other fields of knowledge. "The individual withers, and the world is more and more," to these writers; and in a Buckle, a Draper, and a Taine we all know how much the "world" has come to be almost synonymous with the *climate*. We all know, too, how the controversy has been kept up between the partisans of a "science of history" and those who deny the existence of anything like necessary "laws" where human societies are concerned. Mr. Spencer, at the opening of his *Study of Sociology*, makes an onslaught on the "great-man theory" of history, from which a few passages may be quoted:

"The genesis of societies by the action of great man may be comfortably believed so long as, resting in general notions, you do not ask for particulars. But now, if, dissatisfied with vagueness, we demand that our ideas shall be brought into focus and exactly defined, we discover the hypothesis to be utterly incoherent. If, not stopping at the explanation of social progress as due to the great man, we go back a step and ask, Whence comes the great man? We find that the theory breaks down completely. The question has two conceivable answers: his origin is supernatural, or it is natural. Is his origin supernatural? Then he is a deputy god, and we have theocracy once removed, - or, rather, not removed at all. ... Is this an unacceptable solution? Then the origin of the great man is natural; and immediately this is recognized, he must be classed with all other phenomena in the society that gave him birth as a product of his antecedents. Along with the whole generation of which he forms a minute part, along with its institutions, language, knowledge, manners, and its multitudinous arts and appliances, he is a *resultant*. ... You must admit that the genesis of the great man depends on the long series of complex influences which has produced the race in which he appears, and the social state into which that race has slowly grown. ... Before he can remake his society, his society must remake him. All those changes of which he is the proximate initiator have their chief causes in the generations he descended from. If there is to be anything like a real explanation of those changes, it must be sought in that aggregate of conditions out of which both he and they have arisen."

Now, it seems to me that there is something which one might almost call impudent in the attempt which Mr. Spencer makes, in the first sentence of this extract, to pin the reproach of vagueness upon those who believe in the power of initiative of the great man.

Suppose I say that the singular moderation which now distinguishes social, political and religious discussion in England, and contrasts so strongly with the bigotry and dogmatism of sixty years ago, is largely due to J. S. Mill's example. I may possibly be wrong about the facts; but I am, at any rate, "asking for particulars," and not "resting in general notions." And if Mr. Spencer should tell me it started from no personal influence whatever, but from the "aggregate of conditions," the "generations," Mill and all his contemporaries "descended from," the whole past order of nature in short, surely he, not I, would be the person "satisfied with vagueness."

The fact is that Mr. Spencer's sociological method is identical with that of one who would invoke the zodiac to account for the fall of the sparrow, and the thirteen at table to explain the

gentleman's death. It is of little more scientific value than the Oriental method of replying to whatever question arises by the unimpeachable truism, "God is great." *Not* to fall back on the gods, where a proximate principle may be found, has with us Westerners long since become the sign of an efficient as distinguished from an inefficient intellect.

To believe that the cause of everything is to be found in its antecedents is the starting-point, the initial postulate, not the goal and consummation, of science. If she is simply to lead us out of the labyrinth by the same whole we went in by three or four thousand years ago, it seems hardly worthwhile to have followed her through the darkness at all. If anything is humanly certain it is that the great man's society, properly so called, does *not* make him before he can remake it. Physiological forces, with which the social, political, geographical, and to a great extent anthropological conditions have just as much and just as little to do as conditions of the crater of Vesuvius has to do with the flickering of this gas by which I write, are what make him. Can it be that Mr. Spencer holds the convergence of sociological pressures to have so impinged on Stratford-upon-Avon about the 26th of April, 1564, that a W. Shakespeare, with all his mental peculiarities, had to be born there, - as the pressure of water outside a certain boat will cause a stream of a certain form to ooze into a particular leak? And does he mean to say that if the aforesaid W. Shakespeare had died of cholera infantum, another mother at Stratford-upon-Avon would needs have engendered a duplicate copy of him, to restore the sociologic equilibrium? Or might the substitute arise at "Stratford-atte-Bowe"? Here, as elsewhere, it is very hard, in the midst of Mr. Spencer's vagueness, to tell what he does mean at all.

We have, however, in his disciple, Mr. Grant Allen, one who leaves us in no doubt whatever of his precise meaning. This widely informed, suggestive, and brilliant writer published last year a couple of articles in the *Gentleman's Magazine*, in which he maintained that individuals have no initiative in determining social change.

"The differences between one nation and another, whether in intellect, commerce, art, morals, or general temperament, ultimately depend, not upon any mysterious properties of race, nationality, or any other unknown and unintelligible abstractions, but simply and solely upon the physical circumstances to which they are exposed. If it be a fact, as we know it to be, that the French nation differs recognizably from the Chinese, and the people of Hamburg differ recognizably from the people of Timbuktu, then the notorious and conspicuous differences between them are wholly due to the geographical position of the various races. If the people who went to Hamburg had gone to Timbuktu, they would now be indistinguishable from the semi-barbarian negroes who inhabit that central African metropolis; and if the people who went to Timbuktu had gone to Hamburg, they would now have been white-skinned merchants driving a roaring trade in imitation sherry and indigestible port. ... The differentiating agency must be sought in the great permanent geographical features of land and sea; ... these have necessarily and inevitably molded the characters and histories of every nation upon the earth. ... We cannot regard any nation as an active agent in differentiating itself. Only the surrounding circumstances can have any effect in such a direction. [These two sentences dogmatically deny the existence of the relatively independent physiological cycle of causation. WJ]. To suppose otherwise is to suppose that the mind of man is exempt from the universal law of causation. There is no caprice, no spontaneous impulse, in human endeavors. Even tastes and inclinations *must* themselves be the result of surrounding causes."

Elsewhere Mr. Allen, writing of the Greek culture, says:

"It was absolutely and unreservedly the product of the geographical Hellas, acting upon the given factor of the undifferentiated Aryan brain. ... To me it seems a self-evident proposition that nothing whatsoever can differentiate one body of men from another, except the physical conditions in which they are set, - including, of course, under the term *physical conditions* the relations of place and time in which they stand with regard to other bodies of men. To suppose otherwise is to deny the primordial law of causation. To imagine that the mind can differentiate itself is to imagine that it can be differentiated without a cause. {9}

This outcry about the law of universal causation being undone, the moment we refuse to invest in the kind of causation which is peddled round by a particular school, makes one impatient. These writers have no imagination of alternatives. With them there is no *tertium quid* between outward environment and miracle. *Aut Caesar, aut nullus! Aut* Spencerism, *aut* catechism!

If by "physical conditions" Mr. Allen means what he does mean, the outward cycle of visible nature and man, his assertion is simply physiologically false. For a national mind differentiates "itself" whenever a genius is born in its midst by causes acting in the invisible and molecular cycle. But if Mr. Allen means by "physical conditions" the whole of nature, his assertion, though true, forms but the vague Asiatic profession of belief in an all-enveloping fate, which certainly need not plume itself on any specially advanced or scientific character.

And how can a thinker so clever as Mr. Allen fail to have distinguished in these matters between *necessary* conditions and *sufficient* conditions of a given result? The French say that to have an omelet we must break our eggs; that is, the breaking of eggs is a necessary condition of the omelet. But is it a sufficient condition? Does an omelet appear whenever three eggs are broken? So of the Greek mind. To get such versatile intelligence it may be that such commercial dealings with the world as the geographical Hellas afforded are a necessary condition. But if they are a sufficient condition, why did not the Phoenicians outstrip the Greeks in intelligence? No geographical environment can produce a given type of mind. It can only foster and further certain types fortuitously produced and thwart and frustrate others. Once again, its function is simply selective, and determines what shall actually be only be destroying what is positively incompatible. An Arctic environment is incompatible with improvident habits in its denizens; but whether the inhabitants of such a region shall unite with their thrift the peacefulness of the Eskimo or the pugnacity of the Norseman is, so far as the climate is concerned, an accident. Evolutionists should not forget that we all have five fingers not because four or six would not do just as well, but merely because the first vertebrate above the fishes *happened* to have that number. He owed his prodigious success in founding a line of descent to some entirely other quality, - we know not which, - but the inessential five fingers were taken in tow and preserved to the present day. So of most social peculiarities. Which of them shall be taken in tow by the few qualities which the environment necessarily exacts is a matter of what physiological accidents shall happen among individuals. Mr. Allen promises to prove his thesis in detail by the examples of China, India, England, Rome, etc. I have not the smallest hesitation in predicting that he will do no more with these examples than he has done with Hellas. He will appear upon the scene after the fact, and show that the quality developed by each race was, naturally enough,

not incompatible with its habitat. But he will utterly fail to show that the particular form of compatibility fallen into in each case was the one necessary and only possible form.

Naturalists know well enough how indeterminate the harmonies between a fauna and its environment are. An animal may better his chances of existence in either of many ways, - growing aquatic, arboreal, or subterranean; small and swift, or massive and bulky; spiny, horny, slimy, or venomous; more timid or more pugnacious; more cunning or more fertile of offspring; more gregarious or more solitary; or in other ways besides, - and any one of these ways may suit him to many widely different environments.

Readers of Mr. A. R. Wallace will well remember the striking illustration of this in his *Malay Archipelago*:

"Borneo closely resembles New Guinea not only in its vast size and its freedom from volcanoes, but in its variety of geological structure, its uniformity of climate, and the general aspect of the forest vegetation that clothes its surface; the Moluccas are the counterpart of the Philippines in their volcanic structure, their extreme fertility, their luxuriant forests, and their frequent earthquakes; and Bali, with the east end of Java, has a climate almost as dry and a soil almost as arid as that of Timor. Yet between these corresponding groups of islands, constructed, as it were, after the same pattern, subjected to the same climate, and bathed by the same oceans, there exists the greatest possible contrast when we compare their animal productions. Nowhere does the ancient doctrine that differences or similarities in the various forms of life that inhabit different countries are due to corresponding physical differences or similarities in the countries themselves, meet with so direct and palpable a contradiction. Borneo and New Guinea, as alike physically as two distinct countries can be, are zoologically wide as the poles asunder; while Australia, with its dry winds, its open plains, its stony deserts, and its temperate climate, yet produces birds and quadrupeds which are closely related to those inhabiting the hot, damp, luxuriant forests which everywhere clothe the plains and mountains of New Guinea."

Here we have similar physical-geographical environments harmonizing with widely differing animal lives, and similar animal lives harmonizing with widely differing geographical environments. A singularly accomplished writer, E. Gryzanowski, in the *North America Review*, uses the instance of Sardinia and Corsica in support of this thesis with great effect. He says: "These sister islands, lying in the very center of the Mediterranean, at almost equal distances from the centers of Latin and Neo-Latin civilization, within easy reach of the Phoenician, the Greek, and the Saracen, with a coast-line of more than a thousand miles, endowed with obvious and tempting advantages, and hiding untold sources of agricultural and mineral wealth, have nevertheless remained unknown, unheeded, and certainly uncared for during the thirty centuries of European history. ... These islands have dialects, but no language; records of battles, but no history. They have customs, but no laws; the *vendetta*, but no justice. They have wants and wealth, but no commerce; timber and ports, but no shipping. They have legends, but no poetry; beauty, but no art; and twenty years ago it could still be said that they had universities, but no students. ... That Sardinia, with all her emotional and picturesque barbarism, has never produced a single artist is almost as strange as her barbarism itself. ... Near the focus of European civilization, in the very spot which an *à priori* geographer would point out as the most favorable

place for material and intellectual, commercial and political development, these strange sister islands have slept their secular sleep, like *nodes* on the sounding-board of history."

This writer then goes on to compare Sardinia and Sicily with some detail. All the material advantages are in favor of Sardinia, "and the Sardinian population, being of an ancestry more mixed than [even] that of the English race, would justify far higher expectations than that of Sicily." Yet Sicily's past history has been brilliant in the extreme, and her commerce to-day is great. Dr. Gryzanowski [sic] has his own theory of the historic torpor of these favored isles. He thinks they stagnated because they never gained political autonomy, being always owned by some Continental power. I will not dispute the theory; but I will ask: Why did they not gain it? and answer immediately: Simply because no individuals were born there with patriotism and ability enough to inflame their countrymen with national pride, ambition, and thirst for independent life. Corsicans and Sardinians are probably as good stuff as any of their neighbors. But the best wood-pile will not blaze till a torch is applied, and appropriate torches seem to have been wanting.

Sporadic great men come everywhere. But for a community to get vibrating through and through with intensely active life, many geniuses coming together and in rapid succession are required. This is why great epochs are so rare, - why the sudden bloom of a Greece, an early Rome, a Renaissance, is such a mystery. Blow must follow blow so fast that no cooling can occur in the intervals. Then the mass of the nation glows incandescent, and may continue to glow by pure inertia long after the originators of its internal movement have passed away. We often hear surprise expressed that in these high tides of human affairs not only the people should be filled with stronger life, but that individual geniuses should seem so exceptionally abundant. This mystery is just about as deep as the time-honored conundrum as to why great rivers flow by great towns. It is true that great public fermentations awaken and adopt many geniuses, who in more torpid times would have had no chance to work. But over and above this there must be an exceptional concourse of genius about a time, to make the fermentation begin at all. The unlikeliness of the concourse is far greater than the unlikeliness of any particular genius; hence the rarity of these periods and the exceptional aspect which they always wear.

It is folly, then, to speak of the "laws of history" as of something inevitable, which science has only to discover, and whose consequences any one can then foretell but do nothing to alter or avert. Why, the very laws of physics are conditional, and deal with *ifs*. The physicist does not say, "The water will boil anyhow"; he only says it will boil if a fire is kindled beneath it. And so the utmost the student of sociology can ever predict is that *if* a genius of a certain sort show the way, society will be sure to follow. It might long ago have been predicted with great confidence that both Italy and Germany would reach a stable unity if someone could but succeed in starting the process. It could not have been predicted, however, that the *modus operandi* in each case would be subordination to a paramount state rather than federation, because no historian could have calculated the freaks of birth and fortune which gave at the same moment such positions of authority to three such peculiar individuals as Napoleon III, Bismarck, and Cavour. So of our own politics. It is certain now that the movement of the independents, reformers, or whatever one pleases to call them, will triumph. But whether to do so by converting the Republican party to its ends, or by rearing a new party on the ruins of both our present factions, the historian cannot say. There can be no doubt that the reform movement would make more progress in one year with an

adequate personal leader than as now in ten without one. Were there a great citizen, splendid with every civic gift, to be its candidate, who can doubt that he would lead us to victory? But, at present, we, his environment, who sigh for him and would so gladly preserve and adopt him if he came, can neither move without him, nor yet do anything to bring him forth.

To conclude: The evolutionary view of history, when it denies the vital importance of individual initiative, is, then, an utterly vague and unscientific conception, a lapse from modern scientific determinism into the most ancient oriental fatalism. The lesson of the analysis that we have made (even on the completely deterministic hypothesis with which we started) forms an appeal of the most stimulating sort to the energy of the individual. Even the dogged resistance of the reactionary conservative to changes which he cannot hope entirely to defeat is justified and shown to be effective. He retards the movement; deflects it a little by the concessions he extracts; gives it a resultant momentum, compounded of his inertia and his adversaries' speed; and keeps up, in short, a constant lateral pressure, which, to be sure, never heads it round about, but brings it up at last at a goal far to the right or left of that to which it would have drifted had he allowed it to drift alone.

I now pass to the last division of my subject, the function of the environment in *mental* evolution. After what I have already said, I may be quite concise. Here, if anywhere, it would seem at first sight as if that school must be right which makes the mind passively plastic, and the environment actively productive of the form and order of its conceptions; which, in a word, thinks that all mental progress must result from a series of adaptive changes, in the sense already defined of that word. We know what a vast part of our mental furniture consists of purely remembered, not reasoned, experience. The entire field of our habits and associations by contiguity belongs here. The entire field of those abstract conceptions which were taught us with the language into which we were born belongs here also. And, more than this, there is reason to think that the order of "outer relations" experienced by the individual may itself determine the order in which the general characters imbedded therein shall be noticed and extracted by his mind. The pleasures and benefits, moreover, which certain parts of the environment yield, and the pains and hurts which other parts inflict, determine the direction of our interest and our attention, and so decide at which points the accumulation of mental experiences shall begin. It might, accordingly, seem as if there were no room for any agency other than this; as if the distinction we have found so useful between "spontaneous variation," as the producer of changed forms, and the environment, as their preserver and destroyer, did not hold in the case of mental progress; as if, in a word, the parallel with Darwinism might no longer obtain, and Spencer might be quite right with his fundamental law of intelligence, which says, "The cohesion between psychical states is proportionate to the frequency with which the relation between the answering external phenomena has been repeated in experience."

But, in spite of all these facts, I have no hesitation whatever in holding firm to the Darwinian distinction even here. I maintain that the facts in question are all drawn from the lower strata of the mind, so to speak, - from the sphere of its least evolved functions, from the region of intelligence which man possesses in common with the brutes. And I can easily show that throughout the whole extent of those mental departments which are highest, which are most characteristically human, Spencer's law is violated at every step; and that as a matter of fact the new conceptions, emotions, and active tendencies which evolve are originally produced in the

shape of random images, fancies, accidental out-births of spontaneous variation in the functional activity of the excessively instable human brain, which the outer environment simply confirms or refutes, adopts or rejects, preserves or destroys, - selects, in short, just as it selects morphological and social variations due to molecular accidents of an analogous sort.

It is one of the tritest truisms that human intelligences of a simple order are very literal. They are slaves of habit, doing what they have been taught without variation; dry, prosaic, and matter-of-fact in their remarks; devoid of humor, except of the coarse physical kind which rejoices in a practical joke; taking the world for granted; and possessing in their faithfulness and honesty the single gift by which they are sometimes able to warm us into admiration. But even this faithfulness seems to have a sort of inorganic ring, and to remind us more of the immutable properties of a piece of inanimate matter than of the steadfastness of a human will capable of alternative choice. When we descend to the brutes, all these peculiarities are intensified. No reader of Schopenhauer can forget his frequent allusions to the *trockener ernst* of dogs and horses, nor to their *ehrlichkeit*. And every noticer of their ways must receive a deep impression of the fatally literal character of the few, simple, and treadmill-like operations of their minds.

But turn to the highest order of minds, and what a change! Instead of thoughts of concrete things patiently following one another in a beaten track of habitual suggestion, we have the most abrupt cross-cuts and transitions from one idea to another, the most rarefied abstractions and discriminations, the most unheard-of combinations of elements, the subtlest associations of analogy; in a word, we seem suddenly introduced into a seething caldron of ideas, where everything is fizzling and bobbing about in a state of bewildering activity, where partnerships can be joined or loosened in an instant, treadmill routine is unknown, and the unexpected seems the only law. According to the idiosyncrasy of the individual, the scintillations will have one character or another. They will be sallies of wit and humor; they will be flashes of poetry and eloquence; they will be constructions of dramatic fiction or of mechanical devices, logical or philosophic abstractions, business projects, or scientific hypotheses, with trains of experimental consequences based thereon; they will be musical sounds, or images of plastic beauty or picturesqueness, or visions of moral harmony. But, whatever their differences may be, they will all agree in this, - that their genesis is sudden and, as it were, spontaneous. That is to say, the same premises would not, in the mind of another individual, have engendered just that conclusion; although, when the conclusion is offered to the other individual, he may thoroughly accept and enjoy it, and envy the brilliancy of him to whom it first occurred.

To Professor Jevons is due the great credit of having emphatically pointed out how the genius of discovery depends altogether on the number of these random notions and guesses which visit the investigator's mind. To be fertile in hypotheses is the first requisite, and to be willing to throw them away the moment experience contradicts them is the next. The Baconian method of collating tables of instance may be a useful aid at certain times. But one might as well expect a chemist's note-book to write down the name of the body analyzed, or a weather table to sum itself up into a prediction of probabilities of its own accord, as to hope that the mere fact of mental confrontation with a certain series of facts will be sufficient to make *any* brain conceive their law. The conceiving of the law is a spontaneous variation in the strictest sense of the term. It flashes out of one brain, and no other, because the instability of that brain is such as to tip and upset itself in just that particular direction. But the important thing to notice is that the good

flashes and the bad flashes, the triumphant hypotheses and the absurd conceits, are on an exact equality in respect of their origin. Aristotle's absurd Physics and his immortal Logic flow from one source: the forces that produce the one produce the other.

When walking along the street, thinking of the blue sky or the fine spring weather, I may either smile at some grotesque whim which occurs to me, or I may suddenly catch an intuition of the solution of a long-unsolved problem, which at that moment was far from my thoughts. Both notions are shaken out of the same reservoir, - the reservoir of a brain in which the reproduction of images in the relations of their outward persistence or frequency has long ceased to be the dominant law. But to the thought, when it is once engendered, the consecration of agreement with outward relations may come. The conceit perishes in a moment, and is forgotten. The scientific hypothesis arouses in me a fever of desire for verification. I read, write, experiment, and consult experts. Everything corroborates my notion, which being then published in a book spreads from review to review and from mouth to mouth, till at last there is no doubt I am enshrined in the Pantheon of the great diviners of nature's ways. The environment *preserves* the conception which it was unable to *produce* in any brain less idiosyncratic than my own.

Now, the spontaneous upsettings of brains this way and that at particular moments into particular ideas and combinations are matched by their equally spontaneous permanent tiltings or saggings towards determinate directions. The humorous bent is quite characteristic; the sentimental one equally so. And the personal tone of each mind, which makes it more alive to certain impressions, more open to certain reasons, is equally the result of that invisible and imaginable play of the forces of growth within the nervous system which, irresponsibly [sic; "irresponsive"?] to the environment, makes the brain peculiarly apt to function in a certain way. Here again the selection goes on. The products of the mind with the determined esthetic bent please or displease the community. We adopt Wordsworth, and grow unsentimental and serene. We are fascinated by Schopenhauer, and learn from him the true luxury of woe. The adopted bent becomes a ferment in the community, and alters its tone. The alteration may be a benefit or a misfortune, for it is (*pace* Mr. Allen) a differentiation from within, which has to run the gauntlet of the larger environment's selective power. Civilized Langeudoc, taking the tone of its scholars, poets, princes, and theologians, fell a prey to its rude Catholic environment in the Albigensian crusade. France in 1792, taking the tone of its St. Justs and Marats, plunged into its long career of unstable outward relations. Prussia in 1806, taking the tone of its Humboldts and its Steins, proved itself in the most signal way "adjusted" to its environment in 1872.

Mr. Spencer, in one of the strangest chapters of his *Psychology*, tries to show the necessary order in which the development of conceptions in the human race occurs. No abstract conception can be developed, according to him, until the outward experiences have reached a certain degree of heterogeneity, definiteness, coherence, and so forth.

"Thus the belief in an unchanging order, the belief in *law*, is a belief of which the primitive man is absolutely incapable. ... Experiences such as he receives furnish but few data for the conception of uniformity, whether as displayed in things or in relations. ... The daily impressions which the savage gets yield the notion very imperfectly, and in but few cases. Of all the objects around - trees, stones, hills, pieces of water, clouds and so forth, - most differ widely, ... and few approach complete likeness so nearly as to make discrimination difficult. Even between animals

of the same species it rarely happens that, whether alive or dead, they are presented in just the same attitudes. ... It is only along with a gradual development of the arts ... that there come frequent experiences of perfectly straight lines admitting of complete apposition, bringing the perceptions of equality and inequality. Still more devoid is savage life of the experiences which generate the conception of the uniformity of succession. The sequences observed from hour to hour and day to day seems anything but uniform; difference is a far more conspicuous trait among them. ... So that if we contemplate primitive human life as a whole, we see that multiformity of sequence, rather than uniformity, is the notion which it tends to generate. ... Only as fast as the practice of the arts develops the idea of measure can the consciousness of uniformity simultaneously make possible the notion of *exactness*. ... Hence the primitive man has little experience which cultivates the consciousness of what we call *truth*. How closely allied this it to the consciousness which the practice of the arts cultivates is implied even in language. We speak of a true surface as well as a true statement. Exactness describes perfection in a mechanical fit, as well as perfect agreement between the results of calculations."

The whole burden of Mr. Spencer's book is to show the fatal way in which the mind, supposed passive, is molded by its experiences of "outer relations." In this chapter the yard-stick, the balance, the chronometer, and other machines and instruments come to figure among the "relations" external to the mind. Surely they are so, after they have been manufactured; but only because of the preservative power of the social environment. Originally all these things and all other institutions were flashes of genius in an individual head, of which the outer environment showed no sign. Adopted by the race and become its heritage, they then supply instigations to new geniuses whom they environ to make new inventions and discoveries; and so the ball of progress rolls. But take out the geniuses, or alter their idiosyncrasies, and what increasing uniformities will the environment show? We defy Mr. Spencer or any one else to reply.

The plain truth is that the "philosophy" of evolution (as distinguished from our special information about particular cases of change) is a metaphysical creed, and nothing else. It is a mood of contemplation, an emotional attitude, rather than a system of thought, - a mood which is as old as the world, and which no refutation of any one incarnation of it (such as the Spenserian philosophy) will dispel; the mood of fatalistic pantheism, with its intuition of the One and All, which was, and is, and ever shall be, and from whose womb each single thing proceeds. Far be it from us to speak slightly here of so hoary and mighty a style of looking on the world as this. What we at present call scientific discoveries had nothing to do with bringing it to birth, nor can one easily conceive that they should ever give it its *quietus*, no matter how logically incompatible with its spirit the ultimate phenomenal distinctions which science accumulates should turn out to be. It can laugh at the phenomenal distinctions on which science is based, for it draws its vital breath from a region which - whether above or below - is at least altogether different from that in which science dwells. A critic, however, who cannot disprove the truth of the metaphysic creed, can at least raise his voice in protest against its disguising itself in "scientific" plumes. I think that all who have had the patience to follow me thus far will agree that the Spenserian "philosophy" of social and intellectual progress is an obsolete anachronism, reverting to a pre-Darwinian type of thought, just as the Spenserian philosophy of "Force," effacing all the previous distinctions between actual and potential energy, momentum, work, force, mass, etc., which physicists have with so much agony achieved, carries us back to a pre-Galilean age.

REPLICATING SONORITIES: TOWARDS A MEMETICS OF MUSIC

By

Steven Jan

Department of Music

s.b.jan@hud.ac.uk

Abstract

The memetic paradigm is herein applied to music. While memetics has been used to elucidate a wide variety of cultural phenomena, its concerns to date have largely been with memes in the realm of verbally-expressible concepts. In view of this, this paper represents an attempt to integrate the central concerns of analytical musicology with a neo-Darwinian meme-selectionist perspective. Such a viewpoint may be used, it is argued, to unify, under a systematic new paradigm, understanding of both local issues of musical structure and organization, and global issues of musical style configuration and its diachronic change. Against the grain of several suggestions in the memetics literature, a minimalist view of the musical meme is taken, seeing it as consisting, at the lower extreme, of configurations of as few as three or four notes. The hierarchic location of musical memes is a central concern here, both in cultural hierarchies - i.e., the replication of patterning at different strata within a culture - and in structural hierarchies - i.e., the replication of patterning at different strata within a work, including the level of the global structural archetype. Leonard Meyer's perspective on culture is employed to frame consideration of the first phenomenon, whilst the analytical method of Heinrich Schenker is employed to comprehend the second. In order to understand how musical memes partake of meaning in association with verbally-mediated concept memes, the semiology of Ferdinand de Saussure and Jean-Jacques Nattiez is employed. The article concludes with observations on the transmission and mutation of musical memes, and an account of how this process engenders the evolution of musical styles.

Keywords: Meme, memetics, memeplex, music, musicology, style, hierarchy, Meyer, Schenker, semiology.

1. Introduction: Music and the Memetic Paradigm

In the relatively short time since its inception, contributors to the development of the memetic paradigm, including those writing in this journal, have made valuable progress in the development of memetics as, in Brodie's words, a "...long-awaited scientific theory unifying biology, psychology, and cognitive science..." (1996: 13). Understandably, the debate has largely concentrated on memes in the verbal-conceptual realm, exploring such questions as the growth and spread of religion (Dawkins 1993), the development of sexual taboos (Lynch 1996), and the evolution of information on the Internet (Pocklington and Best 1997).

Nevertheless, Dawkins' now celebrated original definition of the meme was catholic, and indeed began with music, maintaining that "[e]xamples of memes are tunes, ideas, catch-phrases, clothes fashions, ways of making pots or of building arches" (1989: 192). One must therefore remember that our modern view of evolution is, in Dennett's words, *substrate neutral*, meaning that, in the algorithm of evolution by natural selection, "[t]he power of the procedure is due to its *logical* structure, not the causal powers of the materials used in the instantiation, just so long as those causal powers permit the prescribed steps to be followed exactly" (1995: 50-51; his emphasis). [Note 1] This principle is the intellectual foundation of the 'universal Darwinism' Dawkins outlined (1983b), which Plotkin has recently expanded upon (1995), and of which memetics is an important subset.

Given its broad applicability, and observing a niche, it is to music that I aim to apply the memetic paradigm here, attempting to understand the central concerns of musicology [note 2] from a neo-Darwinian meme-selectionist perspective in order to show how such a standpoint may be used to unify understanding of both local issues of musical structure and organization, and global issues of musical style configuration and its diachronic change. [Note 3] Whilst I will largely use as my examples music written in the late-eighteenth and early-nineteenth centuries - a period of such stylistic clarity and coherence the epithet *classical* is deservedly applied to it by musicologists - many of the principles I adduce here are, I believe, applicable to all musics. [Note 4] Moreover, I hope that some observations, given their necessarily contextualizing purpose, make a more general contribution to the debate on memetics, particularly some of the content of Sections 3, 4, 7, and 8. What follows is, however, only a brief outline of what I believe to be the central issues, and I hope to develop the points made here on other occasions.

I begin by examining briefly the relationship between memes in music and those in the verbal-conceptual realm in terms of the linguistic concepts of phonetics, syntax, and semantics. I then consider how memetics offers a means of understanding the characteristics of style in music and, indeed, in culture generally. After exploring the application to musical memes of the genotype-phenotype distinction from biology, I move on to the central parts of the article, which define what I understand as the memetic elements in music, including the nature and hierarchic location of memplexes in music. The final sections of the article deal with the transmission and mutation of musical memes and the way in which this process engenders the evolution of musical style.

During the course of this article it will be necessary to use concepts and terms from music theory and analysis which may not be familiar to the reader. When these are used, notes provide what I hope are clear and non-patronizing explanations. For readers wishing to explore these concepts more fully, Bent and Drabkin 1987, Cook 1994, and Dunsby and Whittall 1988 are excellent sources. For more general information, Sadie 1980 is the most comprehensive reference source in English.

2. Musical Memetics and the Linguistic Analogy

One of the central issues encountered in developing a memetic theory of cultural evolution in analogy with the genetic theory of biological evolution is the fact that ...what is preserved and transmitted in cultural evolution is *information* - in a media-neutral, language-neutral sense. Thus the meme is primarily a *semantic* classification, not a *syntactic*

classification that might be directly observable in "brain language" or natural language. In the case of genes, we are blessed by a gratifyingly strong alignment of semantic and syntactic identity: there is a single genetic language, in which meaning [i.e., what phenotypic feature(s) the gene codes "for"] is (roughly) preserved across all species. (Dennett 1995: 353-354; his emphases)

Nevertheless, even though there is a long critical tradition [note 5] of conceiving music as in some sense akin to verbal language - with, accordingly, a distinct phonetic, syntactic, *and* semantic content - in reality music, unlike primarily referential symbolic systems such as language and painting, has the property of having no fixed semantic structure. To use the language of semiology, referential symbolic systems unite a signifier - a word or image - and a signified - an idea or concept. As Nattiez observes,

By making the sign a union of the signifier and the signified, Saussure conceived of the relationship between the two "faces" of the sign as stable and bi-univocal. Beyond this, the relationship is *arbitrary* [.] (1990: 4; his emphasis)

In music, by contrast, a given configuration - a collection of pitches and rhythms, for instance - does not act as the stable *signifier* for a particular verbally-expressible *signified*, despite the propensity of music to exhibit to a degree of memetic coadaptation which permits specific musical patterns to become associated, in varying degrees of stability, with verbally expressible concepts. This question of music and the signifier-signified dualism - music as signified and music as signifier - is considered in more detail in Sections 6.3 and 6.4 respectively.

In this sense, music's semantic content is low, and its real substance could be said to inhere in its phonetic and syntactic structures. The phonetic presence of music is, as will be discussed in Section 4, a purely phenotypic property. Its syntax, however, whilst reflected phenotypically in, and only readily apparent from, the configuration of musico-graphical patterning in scores, and patterns of sound waves in performance, must presumably inhere at the level of the memotype, i.e., in the form of ordered, grammatical relationships between memes at the level of the neuron. Nevertheless, as Dennett implies, it seems the case that there is no "gratifyingly strong alignment" between neuronal configurations and the musico-syntactic structures they code for.

In contrast to the semantic aspect, the phonetic and syntactic realms are highly developed in the musics of all cultures, the sonorous (phonetic) field consisting of particles which have a combinatorial (syntactic) structure determined not by the constraints of verbal-conceptual logic but by the force of convention. In memetic terms, conventions arise from the differential replication of patterns. The most successful of these become to some degree *evolutionarily stable*, a concept examined in more detail in Section 8. Such patterns - Meyer terms them *strategies* played out within systems of *rules* (1989: 17, 20) - tend to oust rival configurations, which theorists, certainly in the western tradition, then belatedly condemn by deeming them aberrant.

As I hope will become evident from the following discussion, the rich phonetic and syntactic structure of music, together with its relative independence from the complexities engendered by

the rich semantic content of verbal-conceptual memes, makes it an especially lucid medium for memetic analysis. Although the discussion of the memotype-phenotype dualism in Section 4 will indicate this is to be an oversimplification, I shall, in conducting this analysis, take the phonetic and, perhaps more importantly, the syntactic aspects of music to be adequately represented by the musico-graphical content of the printed score.

3. Memetics and Musical Style

Before examining the nature of memes in music, a brief explanation is needed of the relationship between memetics and style analysis, which is deep-seated if one accepts Meyer's definition of style as "...a replication of patterning, whether in human behaviour or in the artifacts produced by human behaviour, that results from a series of choices made within some set of constraints" (1989: 3; my emphasis). Importantly, Meyer and Nattiez note that the pattern replication which defines style occurs at a number of discrete levels in a system of hierarchic inclusion. The following diagram illustrates this concept, reworking the pyramidal representation of the notion of inclusive "levels of stylistic relevance" from Nattiez 1990, and adding corresponding terms from Meyer 1989 in italics. Whilst developed from sources discussing musical style, this perspective is applicable to the replication of memes in all cultural realms:

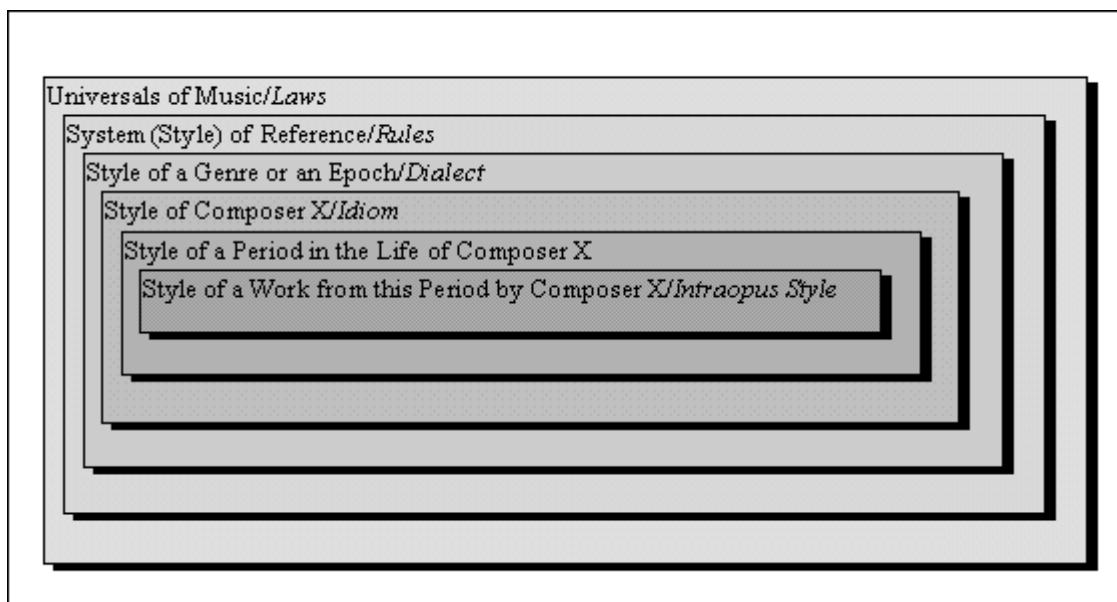

Figure 1: The Hierarchy of Style (after Nattiez 1990: 136, Fig. 6.2 and Meyer 1989: 13-24; see also Jan 1995: 6-7)

Here, *intraopus style* represents the style of - i.e., the totality of memes replicated within - a single work. *Idiom* represents the style of an individual composer within a particular cultural community, and is defined by the sum of the memes replicated within the totality of his or her intraopus contexts. A composer's idiom may, however, be subdivided into a number of chronologically-defined phases or style periods. [note 6] *Dialect* represents the style of a cultural community, defined in geographical (e.g., French, Viennese, Ghanaian) and/or chronological (e.g., Renaissance, Baroque, Classical) terms. *Rules*, the largest memetic aspect of the hierarchy,

are the large-scale systems of musical organization, such as the modal system [note 7] or the major-minor tonal system, [note 8] the generative elements of which are replicated in a number of separate dialects. Finally, *laws* represent invariable, biologically-defined attributes of human perception and cognition which ultimately constrain our responses to music and therefore set limits upon the nature of the memes we assimilate and the profile of their interaction. The *meme pool* might be taken to consist of the totality of memes at the level of dialect or rules:

Figure 2: Stylistic Hierarchies as Meme Pools [note 9]

4. Musical Memes and the Genotype-Phenotype Distinction

Beginning with Dawkins (1983a: 109), many commentators have asserted that memes exist fundamentally as living biological structures, inhering in the patterning of neuronal interconnections. As Delius notes,

Any cultural trait [meme] that is taken over by a given individual from another individual must accordingly be thought of as the transfer of a particular pattern of synaptic hotspots within the associative networks of one brain to the associative networks of another brain. Different traits must be thought of as being coded by topologically different hotspot patterns. That is, a given cultural trait borne by an individual is encoded informationally as a particular pattern of modified synapses in his brain. Naturally the hotspot pattern that a trait has in one brain will not be geometrically arranged in exactly the same way as the pattern that the same trait has in another

brain...But functionally the two hotspot patterns would still be equivalent, at least to the extent that the effective memory contents representing the trait were identical. (1989: 44-45)

Acceptance of this point naturally suggests the application of the *genotype-phenotype* distinction - a differentiation between something hidden and its often far-reaching consequences - to the meme. Whilst care must be taken not to force our thinking on memetics into the straitjacket of earthly DNA, the assimilation of the genotype-phenotype principle is one area where analogizing seems warranted. [Note 10]

4.1. The Memotype and (Extended) Phenotype of Musical Memes

Of the often contradictory formulations of this analogy - essentially part of a wider debate on the ontology of the meme - surveyed by Blackmore (1999: 63-66), that articulated in Ball 1984 and Delius 1989 seems most compatible with the memetics of music I offer here. Accordingly, I take the *memotype* (Grant, in Blackmore 1999: 64) to be the totality of memes - including those coding for musical functions - resident in an individual's brain, existing physically as patterns of neuronal interconnection. The phenotypic - or, by way of distinction, *phemotypic* (Blackmore 1999: 63) - products of memes may be reduced to the two spheres of somatic and extrasomatic effects. The first of these is negligible and includes culturally-determined alterations to the form of a body holding the meme, such as tattooing and piercing. Much more important are the extrasomatic effects, which include patterns of behaviour and the resultant artifacts they motivate and control. These, in turn, facilitate the propagation of memes by engendering their reconstitution, as functionally - but not necessarily structurally - analogous neuronal configurations in the brains of other humans. A musical meme, for instance, may give rise to the behaviours of composition, improvisation, and performance; in terms of artifacts, the meme engenders representations of various kinds on paper, magnetic and compact discs, and, ultimately, the configurations of sound waves for which these media code.

This distinction is essentially that made several years before *The Selfish Gene* by Cloak (1973), who separated *i-culture*, the somatic cultural instructions, and *m-culture*, their resultant behaviour and artifacts. Whatever terms one uses, this perspective has the advantage of mirroring its biological analogue closely and being simple and clear-cut. Moreover, it loosely preserves the distinction Dawkins draws between *replicators* and *vehicles*, whereby the microscopic, invisible, units of replication are clearly distinguished from the large, visible, structures engendered by the replicants to facilitate replication (1983a: Chapter 6). It should be noted, however, that whereas in genetics, replicators are copied ("copy-the-instructions" - Blackmore 1999: 61-62), in memetics it is the vehicles which are copied ("copy-the-product").

Dawkins' concept of the *extended phenotype* enlarges the definition of the phenotype to incorporate

All effects of a gene upon the world. As always, "effect" of a gene is understood as meaning in comparison with its alleles. The conventional phenotype is the special case in which the effects are regarded as being confined to the individual body in which the gene sits. In practice it is convenient to limit "extended phenotype" to cases where the effects influence the survival chances of the gene, positively or negatively. (1983a: 286)

While the phenotypic effects of the gene are both somatic and extrasomatic, the phenotypic effects of the meme are, as noted, almost entirely extrasomatic; and it is in the nature of the meme that one cannot usefully distinguish between its phenotype and its extended phenotype. To paraphrase Dawkins, one may indeed speak of "the long reach of the meme" (after the subtitle to 1983a), meaning that a meme, being at "...the centre of a web of radiating power" (1983a: viii), may both influence the behaviour of its host and also exert its effects at considerable geographical and temporal remove.

As an example of this wide compass, it is clear that memes which appeared initially in symphonies composed by Haydn in the isolation of the Palace of Eszterháza in Hungary in the 1770s continue to copy themselves into the brains of concert goers on the West coast of America in the 1990s; paper-based phenotypic forms of these memes continue to roll from the printing presses of the developed world; and tons of plastic are poured into moulds to make compact disks sustaining other phenotypic incarnations of them.

To draw these points together, Table 1 compares genes and memes in terms of the two pheno/phenotypic spheres, somatic and extrasomatic, offering examples of each category:

REPLICATORS	GENE/PHENOTYPE; MEME/PHEMOTYPE		
	SOMATIC	EXTRASOMATIC	
		BEHAVIOUR	ARTEFACTS
GENE/GENOME	feathers	nest building	nests
MEME/MEMOME	culturally-determined modifications to the body	singing, playing, conducting, improvising, composing	configurations of sound waves, written and printed scores, recordings

Table 1: Genetic and Memetic Pheno/Phenotypes (after Ball 1984: 156, Figure 2)

For a bird, for instance, some of its genes give rise to such phenotypic-somatic features as feathers, and to such phenotypic-extrasomatic behaviours as nest building and the resultant artifacts. For a human, some of its musical memes may give rise to culturally determined modifications to the body, such as the irreparable damage Schumann inflicted upon his hand as a result of using a crude device designed to strengthen the fingers (Daverio 1997: 77-79), and to such phenotypic-extrasomatic behaviours as composition, the artifacts of which are written and printed scores.

4.2. The Ontology of the Musical Work

As noted in Section 4.1, the perspective afforded by the memotype-phenotype dualism raises the question of the ontological status of the meme and, by extension, the status of the larger musical work of which it is a component. In Nattiez's view, "...music's irreducible dimension is *sound*. The musical work *manifests itself*, in its *material* reality, in the form of sound waves" (1990: 69;

his emphases). Nevertheless, he acknowledges the philosophical complications which ensue when the work's "mode of *being*" is considered, noting Ingarden's assertion that ...the work is a purely intentional object, immutable and permanent, whose heteronomous *existence* is no more than a reflection of its *being*: the existence of the work finds its source in the "creative act" of the performer, and its foundation in the score....The score constitutes the work's "schema," which guarantees its identity over the course of history, even though numerous elements not fixed by the score "play an essential role for the aesthetic Gestalt of the work"..., and even though the "schema" allows an enormous number of possibilities for the work's realization. (1990: 69-70)

According to Siohan, however, the notation "...is a graphic element, is neither music, nor its reflection, but a solely mnemonic device. There is no music except in the state of sonorous manifestation" (in Nattiez 1990: 71).

In contrast to the score *versus* sound dualism underpinning these statements, the memotype-phemotype perspective indicates that the musical meme's principal state of being is the somatic neuronal configurations which define its information content. Despite being "...the thing that renders the work performable and recognizable as an entity, and enables the work to pass through the centuries" (Nattiez 1990: 71), the score (and its resultant sound image) is, from the meme's perspective, merely a phemotypic "vessel" to convey it on certain stages of the "long odyssey" from brain to brain (after Dawkins 1989: 33). Seen in this way, one arrives not at a sound *versus* score dualism but rather one of neuronal matrix *versus* score/sound.

Thus, contrary to Nattiez's assertions, one might, in the light of the memotype-phemotype distinction, maintain music's "irreducible dimension" to be somatic memes, and sound waves to be just one of their extended phemotypic artifacts, albeit overwhelmingly the one of greatest importance to most cultures. On this reasoning, the large-scale memeplex that is the musical work exists fundamentally as a temporary alliance of memes in the composer's brain which is subsequently reconstituted in the minds of listeners exposed to its phemotypic products. The freezing of the work by its extended phemotype should not blind us to the fact that the memes that constitute it merely used it as a means of furthering their replication.

Despite this, work-memeplexes have attained a high degree of ontological singularity for us in the West, owing to a crucial memetic event which occurred some two hundred years ago. Goehr, without using the memetic paradigm in her argument, asserts that the closing years of the eighteenth century - not, controversially, the early years of the sixteenth - saw the evolution of a memeplex she terms the *work-concept*. This is an array of memes which cause us ...to see works as objectified expressions of composers that prior to compositional activity did not exist. We do not treat works as objects just made or put together, like tables and chairs, but as original, unique products of a special, creative activity. We assume, further, that the tonal, rhythmic, and instrumental properties of works are constitutive of structurally integrated wholes that are symbolically represented by composers in scores. Once created, we treat works as existing after their creators have died, and whether or not they are performed or listened to at any given time. We treat them as artifacts existing in the public realm, accessible in principle to anyone who cares to listen to them. And when called, finally, to give examples of works, we

usually look to the tradition of western, European, classical, "opus" music, to works, in other words, of a "purely instrumental" or "absolute" sort. (1992: 2)

The propagation of this memplex in the nineteenth century and afterwards gave work-memplexes a far greater cultural salience than they had hitherto enjoyed, according them the status of exhibits in the "imaginary museum of musical works" (Goehr 1992: 8). Before the time of Beethoven, pieces of music were generally seen as transient and ephemeral, the utilitarian products of craftsmanship and labor. After Beethoven - and because of the work-concept memplex - many were seen in terms of the new category of artwork; they came to acquire a degree of permanence and stability, and were supposed the transcendental products of genius and inspiration.

5. Defining the Musical Meme

In defining the meme, in any symbolic form, there are two fundamental and interdependent parameters which one has to consider: *particulateness*, the meme's status as a small, discrete, and self-contained entity, and *coequality*, its status as a unit of imitation, the *sine qua non* of memetic identity. The application of these principles to music is considered below.

5.1. Particulateness

Copying-fidelity upon replication is one of the defining characteristics of the gene - the others are longevity and fecundity (Dawkins 1989: 18, 194) - which Dawkins considers to be "...any portion of chromosomal material that potentially lasts for enough generations to serve as a unit of natural selection....a genetic unit that is small enough to last for a large number of generations and to be distributed around in the form of many copies....a unit which, to a high degree, *approaches* the ideal of indivisible particulateness" (1989: 28, 32, 33). As an undifferentiated segment of a chromosome, the longer a gene, the greater the likelihood that it will be divided - its information content destroyed - during the random cuttings and splicings of the chromosome ('crossing over') which occur during reproduction. Dawkins' definition is founded on his observation that the smaller the gene the greater the statistical probability that it will survive the process of crossing over intact. He does not, however, apply this same logic to the meme when discussing problematic aspects of its definition; again, he uses musical memes as his examples:

So far I have talked of memes as though it was obvious what a single unit-meme consisted of. But of course it is far from obvious. I have said a tune is one meme, but what about a symphony: how many memes is that? Is each movement one meme, each recognizable phrase of melody, each bar, each chord, or what? (1989: 195)

The biological analogy, indeed the replicator concept, would seem to suggest that memes tend toward the latter end of the continuum Dawkins outlines - toward existence as simple rather than complex units. Thus, the more concise a musical meme the greater the likelihood that it will survive the travails of replication by imitation intact. Ultimately, one might assert that the meme shares with the gene the fundamental attribute that it is "...a unit of convenience, a length of chromosome with just sufficient copying-fidelity to serve as a viable unit of natural selection" (1989: 195).

Dennett, however, is reluctant to admit very small particles as memetic. His definition of the meme asserts that:

These new replicators are, roughly, ideas....the sort of complex ideas that form themselves into *distinct memorable units*...Intuitively, we see these as more or less identifiable cultural units, but we can say something more precise about how we draw the boundaries - about why D-F#-A isn't a unit and the theme from the slow movement of Beethoven's Seventh Symphony is: the units are the smallest elements that replicate themselves with reliability and fecundity. We can compare them, in this regard, to genes and their components: C-G-A, a single codon of DNA, is "too small" to be a gene. It is one of the codes for the amino acid arginine, and it copies itself prodigiously wherever it appears in genomes, but its effects are not "individual" enough to count as a gene. A three-nucleotide phrase does not count as a gene for the same reason that you can't copyright a three-note musical phrase: it is not enough to make a melody. (Dennett 1995: 344; his emphasis)

Dennett seems to suggest that whilst three notes can't be memetic, four can, for he maintains that The first four notes of Beethoven's Fifth Symphony are clearly a meme, replicating all by themselves, detached from the rest of the symphony, but keeping intact a certain identity of effect (a phenotypic effect), and hence thriving in contexts in which Beethoven and his works are unknown. (Dennett 1995: 344)

Nevertheless, many listeners would recognize the following song, Johnny Burke's and Erroll Garner's 'Misty' of 1955, from its distinctive opening vocal gesture ("Look at me..."), a collection of just three notes, $b^{\flat 1}-g^1-d^1$. If the memory of a melody can be accessed by hearing its opening notes, this implies that these notes themselves have independent memetic status: [note 11]

Example 1: 'Misty,' bb. 4-7. [note 12]

The issue is, however, not quite as simple as it is presented, for Dennett is blurring the musical parameters of pitch and rhythm. Even the shortest and most self-contained musical meme is seldom an indivisible particle, by which I mean divisible not horizontally (by length), or vertically (by pitch strata), but parametrically. Almost invariably, it is itself a complex of memes in different musical parameters, principally of pitch and rhythmic configurations, but also structures in the realms of dynamics (patterns of loud and soft) and texture (patterns of thick and thin sounds). Example 2 i below, for instance, consists of configurations in pitch - bracketed and labeled meme *x* - and rhythm - meme *y* - which, as shown in ii and iii, have independent existence owing to their replication in other contexts:

The image contains three musical examples, labeled i), ii), and iii), each consisting of a pair of staves (treble and bass clef) in a common key signature (one flat).
 i) Shows a piano concerto excerpt in B-flat major, 3/4 time. The first staff has a box labeled '1' above the first measure. A bracket labeled 'x' spans the first two measures, and a bracket labeled 'y' spans the first four measures.
 ii) Shows a transposed excerpt from Mozart's Die Zauberflöte in B-flat major, 2/4 time. The first staff has a box labeled '1' above the first measure. A bracket labeled 'x' spans the first four measures.
 iii) Shows a piano concerto excerpt in F major, 3/4 time. The first staff has a box labeled '1' above the first measure. A bracket labeled 'y' spans the first four measures. A triplet of eighth notes in the third measure is marked with a '3' and a slur.

Example 2: The Meme as A Parametric Complex

i) Memes x (pitch) and y (rhythm): Mozart, Piano Concerto in B^b major K. 456 (1784) I, bb. 1-4.

ii) Meme x : Pitch Analogue $\uparrow 2 \downarrow 3 \uparrow 1$; [note 13] Mozart, *Die Zauberflöte* K. 620 (1791) no. 13, "Alles fühlt der Liebe Freuden," bb. 1-3, transposed, for ease of comparison, from C major to B^b major. [note 14]

iii) Meme y : Rhythmic Analogue $\downarrow \uparrow \uparrow \downarrow$; Mozart, Piano Concerto in F major K. 459 (1784) I, bb. 1-4.

I will concentrate in this article exclusively on memes in the parameter of pitch, however, because that which Meyer terms the attribute of *syntacticism* is most clearly defined in the realm of pitch, rhythm possessing this property to a lesser extent. He notes that In order for syntax to exist..., successive stimuli must be related to one another in such a way that specific criteria for mobility and closure are established. Such criteria can be established only if the elements of the parameter can be segmented into discrete, nonuniform relationships so that

the similarities and differences between them are definable, constant, and proportional. (1989: 14)

In the western European tradition, at least, memetic structures have evolved most easily in the pitch and, less so, the rhythmic realms, the parameters of dynamics and texture lending themselves rather less readily to "...segment[ation] into discrete, nonuniform relationships....". Having established the parametric interaction of musical memes, Dennett's example, the theme from the opening of Beethoven's Fifth Symphony, could be understood as not just four "notes" but, fundamentally, two pitches, g^1 and $e\sharp^1$, articulated by four rhythmic attacks, γ  | \downarrow |. One could even say that the most distinctive aspect of the theme is not the pitch content but this abstract rhythmic profile - bracketed and labeled as meme x - which, later in the first movement, becomes reduced to a *three* attack rhythm -  | \downarrow |, meme y - a memetic unit of wide currency at this time:

i) 

ii) 

iii) 

Example 3: Rhythmic Memes in Beethoven and Mozart

i) Meme x : Beethoven, Symphony no. 5 in C minor op. 67 (1808) I, bb. 1-5.

ii) Memes x and y : Beethoven, Symphony no. 5 I, bb. 179-190.

iii) Meme *y*: Mozart, Symphony no. 40 in G minor K. 550 (1788) I, bb. 146-150.

Moreover, Dennett's assertion of the memetic status of the theme from the slow movement of Beethoven's Seventh Symphony - all forty-five notes of it (bb. 27-42) - is also problematic, in that he doesn't distinguish between *passive* listeners and *active* composers here. Although, clearly, "...there is a limit to the complexity of musical phrases that can be memorized" (Gatherer 1997: 81), this particular theme is probably not too complex to be held intact in the memory of many musically literate listeners. If so retained, it would qualify in its entirety as a meme. Of course, it also survives, rather more durably, in the form of countless phenotypic representations.

In the work of the composers who were Beethoven's contemporaries and successors, however, this theme, although also copied in their brains as a single-unit meme, was not imitated in their compositions *en bloc*, for what might be called the *anti-plagiarism* concept meme (prolific in western European culture certainly from the beginning of the nineteenth century) would have inhibited this, making it, in Dawkins' words, far too long to be a "...viable unit of natural selection" (1989: 195). Memorizing and then replicating whole chunks of the music of their predecessors and contemporaries is not what composers do: they tend, as I have shown, to replicate the small component units of the musical continuum - either remembered from musico-aural experience or viewed as musico-graphical symbols on paper - navigating the straits between the siren voices of memorability and the rocks of plagiarism.

On this reasoning, one would expect relatively short segments of the theme from the slow movement of Beethoven's Seventh Symphony to have memetic status. Indeed, as Example 4 illustrates, bb. 27-42 might be regarded as a memeplex, a collection of memes which assemble here into a larger pattern (this notion is taken up in more detail in Section 6). The example shows copies of just two of the memes - bracketed and labeled *x* and *y* in the example - which make up this melody: [note 15]

i)

413

ii)

iii)

Example 4: Memes in Beethoven's Seventh Symphony

i) Meme *x*: Mozart, Piano Concerto in C major K. 467 (1785) I, bb. 413-417.

ii) Memes *x* and *y*: Beethoven, Symphony no. 7 in A major op. 92 (1812) II, bb. 27-42.

iii) Meme *y*: Schubert, Piano Quintet in A major D. 667 ('Trout') (1819) I, bb. 1-6.

A further complicating factor in the definition of musical memes is the fact that, discounting all parameters except pitch, one seldom deals with one *stratum* of pitch; rather, in most music, several strata function together, giving rise to harmony, the vertical dimension, and counterpoint, the horizontal dimension. A fragment of music will, typically, consist of a melody line, a bass line, and one or more inner parts, each of which may have its own linear-memetic identity, but which may also form a component of a higher-order meme, a phenomenon discussed in Section 6. Here, for instance, is a three-component meme, a version of the so-called *perfect cadence* (i.e., the harmonic progression V-I, in this case preceded by an altered form of chord II), made up, contrary to Dennett's assertion, of three distinct vertical units (chords) and four replicated horizontal units (melodic lines):

i) 

ii) 

Example 5: A Three-Component Cadential Meme

i) Bach: *Matthäus-Passion* BWV 244 (c. 1729-c. 1744) no. 25, Chorale "Was mein Gott will, das g'scheh' allzeit," bb. 3-5.

ii) Bach: *Matthäus-Passion* no. 40, Chorale "Bin ich gleich von dir gewichen," bb. 9-11.

One could even assert the memetic status of the following two-component perfect cadential patterns, for the end-segments, the harmonic progression V-I, are identical, yet are preceded by different penultimate configurations:

126

i)

268

ii)

Example 6: A Two-Component Cadential Meme

i) Mozart: Piano Sonata in D major K. 284 (205b) (1775) I, bb. 126-127.

ii) Beethoven: Piano Trio in D major op. 70 no. 1 ('Ghost') (1809) I, bb. 268-270.

Ultimately, however, Dennett concedes that "...there is no 'principled' lower limit on the length of a sequence that might come to be considered a gene or a meme" (1995: 344), despite previously asserting four as the nominal value in discussion of Beethoven's Fifth Symphony. Observing that "...Beethoven is the favorite example for illustrating this problem," Blackmore considers this question of meme size, essentially taking Dennett's "...smallest elements that replicate themselves with reliability and fecundity" as the most secure criterion (1999: 53-56). The concept of *coequality* is offered in Section 5.2 as a means of resolving difficulties of this kind.

Given these various qualifications, in defining the musical meme, one may therefore assert that any discrete musical segment which a composer assimilates from his or her environment may be held to be memetic, and that such a segment will tend to be the union of a *short* melodic fragment, a *simple* chord progression, or a *concise* rhythmic pattern. Thus, to demarcate musical memes one needs, in the words of Bent and Drabkin, "...to break the stream of music into component units (or 'unities' - i.e. units that either cannot be further subdivided or do not need to be because their sub-units never occur independently)" (1987: 96). Whilst offered as a summary

of the working methods of *distributional analysis*, [note 16] this principle both holds for the definition of the meme, and neatly parallels that Dawkins gives for the gene.

5.2. Coequality

From a memetic standpoint, however, the subdivision into "unities" takes place by reference to other copies of that unit, identifying that portion of the pitch and/or rhythmic continuum which is replicated. "[A]n item of brain-stored memory" has been termed a *mnemon* by Lynch (1998). For such a particle to be regarded as a meme, a unit of imitation, one must, by definition, isolate the copy/copies - what one might term the coequal/s - of the particle, from which the particle is imitated, or which is/are derived by imitation of the particle, for "[w]hen copied from one brain to another, [a mnemon] becomes a meme" (1998). It will be understood that particularity, the segmentation of the symbolic stream, can only be defined by reference to coequality, the presence of analogous segments of the same or another symbolic stream, and not by means of potentially deceptive surface articulations in the symbolic stream.

A coequal can exist at any level of the stylistic hierarchy discussed in Section 3, although in reality the coequal can exist in concrete form only at the level of intraopus style. Therefore a (musical) meme may exist abstractly at the level of dialect or idiom, but can only exist in reality at the level of the individual work. Here, as explained in Section 4, it manifests itself extrasomatically/phemotypically, but primarily derives from a somatic form in the composer's brain. In the absence of a proven coequal (or because the sheer magnitude of that which one has to investigate militates against identification of coequality, a particular problem in the memetic analysis of music), one might perhaps instead need to invoke a probabilistic perspective, positing the statistical probability of the existence of a coequal of given meme - without which, by definition, that mnemon would not attain memetic status - somewhere in the dialect at a particular point in time.

If the coequal of a mnemon Mn is identified one has to determine whether it is possible to verify if the coequal is the direct - i.e., causal - antecedent or consequent of Mn or whether the resemblance is adventitious. Dennett notes that "[t]his is the same epistemological problem, in the science of culture, that taxonomists confront when they try to sort out homology [resemblance due to direct descent] from analogy [resemblance due to fortuitous *convergent evolution*], ancestral from derived characters, in cladistic [species' family tree] analysis" (1995: 357). Ultimately, it may be impossible to resolve such questions, for the complexity of human communities and the convoluted modes of interaction between their members - particularly the admixture of horizontal and vertical modes of transmission - make verification of causality highly problematic. A workable definition of the meme probably ought not, in consequence, to contain a stipulation that a causal connection be verified between two equivalent particles, merely that a given particle has a coequal.

It is clear that a definition of coequality is more difficult in the case of two mnemons, Mn^x and Mn^y , which are similar in configuration but not identical to each other, for in such situations one must determine, using substrate-appropriate criteria, whether they merit the status of coequals, and hence memes. In such cases, Mn^y might be judged to be sufficiently different from Mn^x to be regarded as a mutant form of it, although it is not always apparent, even using chronological

evidence, which is the antecedent and which is the consequent in a pair of mnemons in an assumed evolutionary relationship. If Mn^x and Mn^y are considered sufficiently different to preclude identity as coequals, their individual memetic status depends, of course, upon the existence of a coequal for each.

As Figure 3 illustrates, to regard Mn^y as a mutant form of Mn^x (or *vice versa*) implies direct evolution, by definition a causal process, whereas in reality the relationship might be one between independently generated variants of a single antecedent, Mn^a (Figure 3 i); or between two independently generated mnemons, each deriving from its own antecedent, Mn^a and Mn^b (Figure 3 ii):

Figure 3: Potential Ambiguities in Relationships Between Mnemons

It is often the case that a given span of music may contain two or more *interlocking* and/or *nested* memes, each segmentation of the pitch or rhythm matrix being defined and verified by reference to a coequal in another context - either the same work or a different one. Figure 4 represents this diagrammatically, with a musical illustration of nesting given in Example 7 i-v. Here a phrase by Mozart is shown to contain several nested memetic melodic segments, bracketed and labeled with the letters *a-d* (Example 7 ii is transposed to the key of C, the key of Example 7 i, iii, iv, and v). Example 7 vi (transposed to C) and vii, whilst not demonstrating interlocking or nesting, are added in order to show the coequals - bracketed and marked *e* and *f* - of other memes in i:

Figure 4: Interlocking and Nested Memetic Segmentations

The musical score illustrates the two types of segmentations in a musical context. It is divided into two main sections, i) and ii).

- Section i) Interlocking Segmentation:** Shows a musical phrase starting at measure 1. The treble clef staff has notes with annotations 'a', 'b', 'c', and 'd' above them, connected by horizontal lines. The bass clef staff has notes below. A double bar line is present after the first measure.
- Section ii) Nested Segmentation:** Shows a musical phrase starting at measure 15. The treble clef staff has notes with annotation 'a' above them, connected by a horizontal line. The bass clef staff has notes below. Vertical arrows point from the treble staff notes down to the bass staff notes at specific measures.

iii) 1

iii)

iv) 7

iv)

v) 13

v)

vi) 66

vi)

vii)

Example 7: Nested Memetic Segmentations

- i) Mozart: Five Divertimenti for Three Bassett Horns K. 439b (1783-1788) no. 1, III, bb. 1-9.
- ii) Mozart: Serenade in B^b major K. 361 (370a) (c. 1781) I, bb. 15-18.
- iii) Mozart: Missa Brevis in C major K. 220 (196b) (*Spatzen-Messe*) (1775) Agnus Dei, bb. 1-2.
- iv) Mozart: Missa Brevis in C major K. 220 (196b) Gloria, bb. 7-9.
- v) Mozart: *Die Entführung aus dem Serail* K. 384 (1782) no. 11, "Martern aller Arten," bb. 13-15.
- vi) Mozart: Serenade in C minor K. 388 (384a) (1782) I, bb. 66-68.
- vii) Mozart: Adagio and Rondo in C minor/major K. 617 (1791), bb. 1-2.

Note that the principle of coequality imposes articulation and segmentation on the two or more contexts in which replication occurs. A particulate, quasi-digital order - inhering ultimately at the level of the psychological representation - is engendered within what would otherwise be undifferentiated, quasi-analogue streams of musical data.

6. Structural Hierarchies and the Musical Memplex

6.1. Pitch-Based Structural Hierarchies

In Section 3 I discussed the question of the hierarchy of musical style, defining style in terms of the cultural level at which memes were replicated, from the individual works of a composer to dialects spanning great swathes of time and space. There is, however, another and more fundamental sense in which musical memes exist hierarchically, as the following passages illustrate:

i)

...1

ii)

iii)

iv)

v)

vi)

vii) a)

b) 1

c) 14

d) 5

e) 1

Example 8: Memes at Various Hierarchic Levels

i) Mozart: Flute Quartet in A major K. 298 (?1786) II, Minuet, bb. 1-8. [note 17]

ii) Voice-Leading Reduction of i.

iii) Mozart: Adagio in C major for Glass Harmonica K. 356 (617a) (1791), bb. 1-8, transposed to D major.

iv) Voice-Leading Reduction of iii.

v) Mozart: Flute Quartet in A major K. 298 II, Trio, bb. 1-8.

vi) Voice-Leading Reduction of v.

vii) Coequals of Memes 1-5, transposed to D major:

a) Meme 1: Beethoven, Symphony no. 9 in D minor op. 125 (1824) III, bb. 91-93.

b) Meme 2: Mozart, Symphony in C major K. 338 (1780) I, bb. 1-4.

c) Meme 3: Haydn, *Die Schöpfung* Hob. XXI: 2 (1798) no. 32, "Holde Gattin!", bb. 14-16.

d) Meme 4: Beethoven, Symphony no. 8 in F major op. 93 (1812) I, bb. 5-8.

e) Meme (1+) 5: Mozart, Piano Quartet in G minor K. 478 (1785) II, bb. 1-4.

Examining the extracts at i and iii it will be evident that several segments from the flute quartet passage are copied almost exactly in the Adagio; these correlations are bracketed in the example and numbered 1-5. It is possible automatically to define these segments as memetic, for those in the first passage are copied in the second; indeed, the segmentation of the first passage is carried out, as discussed in Section 5.2, on the basis of that which is copied in the second. Nevertheless, an alternative reading of the passage would regard it as possibly controlled not by several discrete memes, but rather by a *single unit meme*, even though the length of the passage - and the presence of connecting material not replicated in both examples - somewhat militates against this interpretation.

To discount the single unit meme reading properly, it is necessary to ascertain the memetic status of the individual bracketed particles. Although one might only imply - on probabilistic grounds - the existence of other copies of these memes elsewhere in the dialect, it is prudent to attempt definitively to locate copies. Part vii a-e of Example 8 shows such copies, giving a coequal of each of memes 1-5 from other works from the dialect of Viennese Classicism.

Perhaps the best way to regard the passages in i and iii is to regard them as two copies of a *coadapted meme complex* or, to use Cees-Speel's term, a *memeplex* (in Blackmore 1999: 19).

[note 18] As Dawkins notes,

Memes, like genes, are selected against the background of other memes in the meme pool. The result is that gangs of mutually compatible memes - coadapted meme complexes or memeplexes - are found cohabiting in individual brains. This is not because selection has chosen them as a

group, but because each separate member of the group tends to be favored when its environment happens to be dominated by the others. (in Blackmore 1999: xiv)

Having ascertained the memetic status of the individual segments in the passages, the replication, in order, of the memes of extract i in the passage at iii allows us to speak with some confidence of the replication of a memeplex in these phrases. As a general principle, then, a memeplex may only consist of units *which are also replicated independently* of their preferred partners and which in association form a class of at least two. If a replicated complex of discrete units exists *only* in this form, one must regard this larger, encompassing, unit as the meme, in which case no memeplex exists. Conversely, what might initially appear to be two large single unit memes - as in Example 8i and iii - might be better regarded as memeplexes. Such a determination, however, hinges upon the hierarchic location of the replicated unit(s). A middle ground structure - as in Example 8 ii and iv - might be regarded as a single unit meme, with copies existing at various hierarchic levels in other contexts, whereas the configurations generating this pattern may also demonstrate memetic existence independently of the memeplex into which they ostensibly assemble.

The 'voice-leading reductions' at Example 8ii and iv strip i and iii down to their fundamental framework using a method of analysis developed by the influential Austrian music theorist Heinrich Schenker (1868-1935) in which notes deemed, on various criteria, to be of lesser importance are gradually removed. [note 19] It is evident that the *foreground* events of the passages in i and iii generate a *middle ground* structure - the *interrupted linear progression* $\overset{5}{3}/\overset{4}{2}-\overset{3}{2}/\overset{V}{1} \parallel \overset{5}{3}/\overset{4}{2}-\overset{3}{2}/\overset{V}{1}/\overset{1}{1}$ [note 20] - which is essentially common to both passages, aside from a few minor details of voice alignment and disposition of scale degrees. Because this structure is replicated - it occurs more than once - it is, by definition, of memetic status. It is a meme at a deeper level of structure, but is not necessarily *confined* to that level; one might easily find examples of replicated patterns based upon this scale degree succession situated closer to or at the foreground level.

Part v of Example 8 shows the theme of the first half of the Trio of K. 298 III. Despite the fact that its foreground harmonic and melodic organization is quite different from that of the first half of the Minuet, i, and of the opening of the Adagio, iii, its middle ground organization is essentially that of the passages in which the memeplex is replicated, ii and iv. This illustrates the point that a meme at a level of structure below the foreground may be expressed by a variety of foreground configurations. In the present case, the middle ground meme in ii and iv is expressed both by a memeplex located at the foreground, i and iii, and by a sequence of foreground events, v, which - to my knowledge - is not a memeplex.

On the evidence of the above examples, it is logical to suggest that, in addition to foreground-located memeplexes, such complexes may also be situated at the middle ground level. In such a situation, discrete middle ground events in one piece would be replicated in sequence in another, both complexes generating a common *background* pattern. This is, of course, analogous to the situation presented in Example 8 i-iv, but located at one level of structure deeper (assuming, for simplicity's sake, three principal structural levels; in some analyses, Schenker often identifies more than one middle ground stratum). Figure 5 represents these relationships diagrammatically: [note 21]

i)	<i>Urlinie</i> $\hat{5}-\hat{1}$.				
	$\hat{5}$	$\hat{4}$	$\hat{3}$	$\hat{2}$	$\hat{1}$
ii)	Middleground Structures: Constituent Scale Degrees.				
	a)	b)	c)	d)	e)
	<u>$\hat{5}-\hat{4}-\hat{3}-\hat{2}-\hat{1}$</u>	<u>$\hat{4}-\hat{3}-\hat{4}$</u>	<u>$\hat{3}-\hat{4}-\hat{3}$</u>	<u>$\hat{5}-\hat{4}-\hat{3}-\hat{2}$</u>	<u>$\hat{5}-\hat{4}-\hat{3}-\hat{2}-\hat{1}$</u>
iii)	Foreground Memes M^1-M^{20} .				
	M^1-M^5	M^6-M^8	M^9-M^{11}	$M^{12}-M^{15}$	$M^{16}-M^{20}$

Figure 5: Memeplexes at Various Structural Levels

At level iii of this hypothetical example, twenty foreground memes, M^1-M^{20} , each express (i.e., are principally based around) a single scale degree. These memes are shown as associating to form five groups. The first group of memes, M^1 , M^2 , M^3 , M^4 , and M^5 , for instance, might express the scale degrees $\hat{5}$, $\hat{4}$, $\hat{3}$, $\hat{2}$, and $\hat{1}$ respectively, giving rise to a middle ground linear progression $\hat{5}-\hat{1}$, shown in Figure 5 ii a. Each of these middle ground structures might, in turn, express a component (underlined in Figure 5 ii) of the $\hat{5}-\hat{4}-\hat{3}-\hat{2}-\hat{1}$ *Urlinie* shown in Figure 5 i. The fifth middle ground structure, ii e, for instance, another $\hat{5}-\hat{1}$ linear progression and itself generated by the group of memes $M^{16}-M^{20}$, might express the final pitch, the $\hat{1}$, of the *Urlinie*.

It will be evident that each middle ground structure in Figure 5 ii is a meme; examples may be found throughout the dialect of $\hat{5}-\hat{4}-\hat{3}-\hat{2}-\hat{1}$ middle ground linear progressions, such as that expressed in bb. 18-22 of the first movement of Mozart's Piano Sonata in C major K. 545 (1788), illustrated in Schenker 1979 as Fig. 88 4 c. Moreover, if, by analogy with the foreground memes in the passage in Example 8 i, these five middle ground structures a-e were replicated *in sequence* in another work at the same level, as is analogically the case in Example 8 iii, they would clearly constitute a middle ground memeplex. As with the memeplex in Example 8 i and iii, such a memeplex will generate a meme at a still deeper structural level: in the same way that the foreground memeplex of Example 8 i and iii gives rise to the middle ground meme of Example 8 ii and iv; correspondingly, the middle ground memeplex of Figure 5 ii and its coequal in another work will give rise to the background meme of Figure 5 i and its coequal in that other work.

Furthermore, just as the middle ground structure shown in Example 8 ii, iv, and vi was not dependent upon the *specific* set of foreground memes present for its expression - this being evident from the divergence at the foreground level between the passages in Example 8 i and iii on the one hand and Example 8 v on the other - so the background structure in Figure 5 i is not contingent upon a *specific* set of middle ground memes for its expression. Indeed, one of the basic tenets of Schenkerian theory proposes a dualism between the limited number of background forms and the virtually unlimited number of middle ground and foreground patterns. Nevertheless, it is logical to infer, as does the previous paragraph, that the replication of a middle

ground memplex - whether or not it is *itself* engendered by a foreground memplex - will give rise to identical background memes, just as the replication of a foreground memplex will generate identical middle ground memes. [Note 22]

This relationship between proximate events and more remote phenomena is essentially that conceptualized by Gjerdingen as the *schema-features* dichotomy. Both Gjerdingen (1988) and Meyer (1989) have written at length on musical patterns they term variously *archetypes* and *schemata*. [note 23] These are perceptual/conceptual frameworks being determined by, and determining, the nature and disposition of a number of lower-level elements, termed *features* by Gjerdingen. Thus, "[s]chemata can be defined as meaningful sets of features, and features can be defined as meaningful elements in sets of schemata" (1988: 6). From the point of view of the composer, schemata are primarily synthetic, generative tools, guiding the creative process; from the point of view of the listener they are analytical aids, directing the processes of perception and cognition.

Implicit in the Meyer-Gjerdingen notion of a schema is the principle of recurrence: schemata are replicated patterns of relationships and are, by virtue of this replication, necessarily memetic. If one regards the schema as a middle ground event and its constituent features as foreground phenomena, it will be evident, in the light of the discussion of Example 8 and Figure 5 that a diversity of foreground features may assemble to generate a specific middle ground schema.

6.2. Structural Memes in Music

It is logical to extend the hierarchic perspective adopted in discussion of the relatively circumscribed examples of Section 6.1 to the complex, large-scale patterns which composers repeatedly employ as the overarching structural framework of their compositions. Such archetypal configurations exist because they are repeatedly reinstated - replicated - by memes at more immediate levels of musical organization.

Cook argues, on the basis of several empirical studies, that these structures seem to have little tangible reality for listeners, suggesting that

...few people actually experience musical compositions as such, in the sense of constituting them as fully co-ordinated, objective structures. Unless they have both the training and the inclination to track the form of a piece of music in theoretical terms as they listen, people experience recurrence without actually observing what it is that recurs; they experience coherence but not the unitary organization in terms of which a theorist or analyst would explain that coherence. People enjoy musical compositions, in other words, without really perceiving them at all; rather than listening *to* them...they "just listen." (1990: 68)

Nevertheless, they apparently had clear existence for composers, for as Drabkin notes, apropos of Beethoven:

...we know that he studied the music of his predecessors Haydn and Mozart and modeled a number of sonata-type works of the 1790s and early 1800s on specific works by Mozart [Beethoven's String Quartet in A major op. 18 no. 5 (c. 1799) is, for instance, closely modeled on

Mozart's String Quartet in A major K. 464 (1785)]. If a piece by Mozart could suggest to Beethoven a set of procedures to be followed - with modifications - to produce another piece, then he probably did not regard the growth processes in a particular piece as the exclusive property of that piece. (In Kinderman 1991: 15)

This is equivalent to saying that Beethoven - indeed probably most composers working in traditions with strongly developed notions of form and genre - perceived a fairly clear separation between a work's global organization and its detailed content. He realized that a given structural configuration might receive many instantiations each of which was unique in its local details but all of which shared broadly analogous "growth processes."

Given this process of replication by repeated instantiation, it is a small step to the view that the fundamental archetypes of music are memes - *structural memes* - at the largest dimensions and highest hierarchical levels of musical organization; they are, to use Gjerdingen's terminology, superordinate schemata which may be instantiated by a diversity of subordinate features. Given this, one can conceive of interplay, perhaps indeed tension, between the top-down processes of the structural memes (which require and perhaps select memes at lower hierarchic levels for their generation and replication), and the bottom-up processes of the memes at lower hierarchic levels (which selfishly pursue their own replication without regard for the structural memes which they generate and replicate). Moreover, one might even envision a process of allelic rivalry between lower-level memes in the competition to occupy the *loci* in a structural archetype.

How structural memes should be conceptualized and described has been one of the great debates of music theory and, latterly, music analysis. These disciplines have, moreover, had to keep pace with the evolution of structural memes over the last four hundred years. Conceptual memeplexes assembled to account for such configurations include, in roughly chronological order, Quintillian rhetoric (Burmeister, *c.* 1600), phrase assemblage (Koch, *c.* 1780), formal models (Marx, *c.* 1840), voice-leading strata (Schenker, *c.* 1930), motivic elaboration (Réti, *c.* 1950), and Chomskyan generative grammar (Lerdahl and Jackendoff, *c.* 1980). [note 24] It will be realized that these conceptual memeplexes are themselves subject to variation and selection (including by the criterion of fit with that which they aim to elucidate) over time and, as a result, undergo evolution in association with the structures they endeavor to describe.

I hope to return to this question of deep structural archetypes in music and their evolution - the musical analogue to Dawkins' 'blind watchmaker' principle (1991) - on another occasion. [note 25] Before leaving the issue, however, it should be noted that structural memes clearly retain the fundamental characteristics of memes at lower hierarchic levels, in that they are composed of a relatively small number of discrete components in a clear and distinct relationship with each other. The observations made in Section 5.1 on the implications of the memetic attributes of copying fidelity and fecundity would therefore appear to apply to memes irrespective of the hierarchic level at which they are propagated. Whether one chooses to speak in terms of traditional formal models, such as binary, ternary, or sonata form; [note 26] the Schenkerian *Ursätzen* $\mathfrak{3}-\hat{1}$, $\mathfrak{5}-\hat{1}$, or $\mathfrak{8}-\hat{1}$; or the *normative prolongational structure* proposed by Lerdahl and Jackendoff, [note 27] one is essentially dealing with small memes - particulate entities consisting of relatively few elements - despite their generally expansive temporal arch.

6.3. The Psychological Organization of Musical Memes

As is discussed in Section 4, the patterns analyzed in Example 8, as with all memes, exist fundamentally as neuronal configurations within the brain. Whilst a detailed treatment of the neurobiology of memory is beyond the scope of this article, [note 28] the matters covered in Section 6.1 warrant a return to this question from the perspective of psychology, examining the issues of hierarchical location in musical memetics in terms of the psychology of memory organization. In discussing the schema-features dualism, Gjerdingen notes that we demonstrate two types of memory structure, termed *semantic* and *episodic* by Tulving; these correspond to the classifications *categorical* and *schematic*, respectively, proposed by Mandler (Gjerdingen 1988: 59). It should be noted, however, that these are psychological, not neural models, nor are they as separate as the following necessarily simplified exposition implies.

Semantic/categorical memory takes the form of an *associative network* of information-encoding memory nodes (memes) and their interconnections. Delius notes that "[s]uch plastic synapses have to be thought of as the critical components of neural networks that function as associative arrays" (1989: 44; see also his Figure 2; and Gjerdingen 1988: Figures 4-1, 4-2). The memory patterns for foreground features such as memes 1-5 in Example 8 i and iii would seem to be subject to this type of organization. In contrast, episodic/schematic memory structures the recall of discrete events anchored in linear time. The memory patterns for a middle ground schema such as that shown in Example 8 ii, iv, and vi, with its clear sequence of component events, would seem to be subject to this type of organization. These two models of memory organization may be represented diagrammatically as follows:

Figure 6: Semantic/Categorical and Episodic/Schematic Memory (after Gjerdingen 1988: Figures 4-1, 4-2, 4-3)

Having outlined their differences, Gjerdingen asserts that

These two types of memory organization commingle if we allow the term *feature* for event schema to coincide with the term *concept* for semantic[/categorical] networks....[I]n music, *dominant seventh chord*, for example, can be both a concept linked to the memory nodes *instability*, *dissonance*, and so on, and a feature in the [episodic/]schemata[ti]c *perfect authentic cadence*.... (1988: 61; his emphases)

In the light of the discussion of Example 8, one might suggest that foreground-orientated memes (features) are coded by the individual neural nodes in a semantic/categorical associative network; and that middle ground-orientated memes (schemata) are the consequence of the organization of these nodes into sequential configurations fixed in and mediated by episodic/schematic memory. Moreover, these middle ground memes then act as features coded by the nodes of a higher-order semantic/categorical associative network; these are themselves fixed sequentially into a superordinate episodic/schematic configuration (the highest level schema), of which the *Ursatz* is one representation. In this sense, the hierarchic, embedded, nature of memory organization gives rise to the hierarchic, embedded, nature of musical organization.

Despite its congruence with observed musical phenomena, Gjerdingen's synthesis of the two forms of memory organization in the extract cited above tends to blur the distinction between signifiers and signifieds. One method of clarification would be to regard the spoken (verbal-phonetic) and written (verbal-graphical) patterning 'dominant seventh chord' as the phenotypic products of somatic memes which act as signifiers. [note 29] To this category one should add the memes antecedent to such phenotypic products as the written (musico-graphical) patterning of the dominant seventh chord:

Figure 7: The Musico-Graphical Symbology of the Dominant Seventh Chord

Together, and in coadaptation with an array of other memes, these form the matrix of concept memes - the network of interlinked notions Peirce termed *interpretants* (in Nattiez 1990: 6) - which structure our verbal-conceptual cognition of this chord.

Whilst to some extent independent, these three signifier memes also exist in coadaptation with the somatic *sonority meme*, our mental image of the sound - i.e., the sound internalized ('heard') in the brain - which operates as their signified and whose phenotypic product, via the intercession of musical instruments, is the physical sonority through which the dominant seventh chord impinges upon us most directly. This complex relationship is illustrated below: [note 30]

	MEMOTYPE	PHEMOTYPE
SIGNIFIERS	Verbal-Phonetic Meme Dominant Seventh	Verbal-Phonetic Pattern "Dominant Seventh"
	Verbal-Graphical Meme Dominant Seventh	Verbal-Graphical Pattern "Dominant Seventh"
	Musico-Graphical Meme 	Musico-Graphical Pattern " 
SIGNIFIED	Sonority Meme 	Physical Sonority 

Figure 8: The Memetic Constellation of The Dominant Seventh Chord

It will be understood that in verbal signification systems, the somatic signifier - the verbal-phonetic and/or verbal-graphical memes antecedent to the language-specific spoken and/or written word - and the somatic signified - the idea or concept with which they are stably united - give rise to a unitary phemotypic manifestation, a spoken and/or written verbal configuration. In music, by contrast, a separation is maintained, in that the somatic signifier - the memes antecedent to the verbal-phonetic and/or verbal-graphical phrase 'dominant seventh chord' and/or the musico-graphical image shown in Figure 7 - and the somatic signified - the memes antecedent to the physical sonority - give rise to separate manifestations which preserve the signifier-signified dualism at the level of the phemotype.

6.4. Topics

In the previous section, musical memes were understood to act as the signified element of semiological memeplexes in which verbal-conceptual memes acted as the signifier. Another sense in which music forms semiological memeplexes is in contexts where a musical meme acts, conversely, as a signifier, becoming associated with verbal-conceptual memes, which are the signified. Musicologists such as Ratner (1980: 9 ff.) and Allanbrook (1983: 1 ff.) tend to refer to such memeplexes as *topics*. Another figure in this tradition, Agawu, observes that A topic, T, may be defined as a musical sign. Each T embodies the union of a signifier and a verbally mediated signified. Signifiers are purely musical dimensions such as texture, timbre, rhythm, melody, and harmony *in a particular disposition*....The signified or concept is represented by an arbitrary label drawn from [the] U[niverse of] T[opic and] normally point[s] to dimensions of historical or sociocultural specificity, including the elements of a contemporary compositional code. (1991: 128-129)

An example of a topic is the chromatic descending tetrachord pattern, which consists of the motion from the tonic of the key to its dominant (the fifth note) downwards by semitones. [note 31] From Monteverdi to Beethoven, this meme was regularly replicated in coadaptation with texts expressing death, grief, and the funereal. In the following passage from Purcell, the tetrachord is bracketed:

Example 9: A Descending Chromatic Tetrachord in Purcell

i) Musical Signifier: Purcell, Dido's Lament from *Dido and Aeneas* (1689), bb. 6-12.
Text: When I am laid in earth, may my wrongs create no trouble in thy breast.

ii) Verbal-Conceptual Signified: Coadapted Concept Memes

Death Grief Lamentation Sorrow

If theorists of this period are to be believed, the strength of the association was such that even without the verbal-conceptual signified, the musical signifier alone called forth the coadapted concept memes in the minds of contemporary listeners. Indeed, these associations endure today. Hopkins, for example, describes the following passage, from Beethoven's Ninth Symphony, as "...a funeral march. Its foundation is a chromatic wailing in the bass [the tetrachord, bracketed] above which brass and wind proclaim funereal fanfares" (1981: 259):

Example 10: A Descending Chromatic Tetrachord in Beethoven: Symphony no. 9 in D minor op. 125 (1824) I, bb. 513-517 (Hopkins 1981: 259, Ex. 255)

As Figure 2 indicates, the topic exists at the level of dialect - the association of musical meme with concept meme is copied in all the brains of the members of a given cultural community - but also shares the meme pool with analogous memeplexes consisting of personal associations of musical memes and concept memes at the level of idiom. A composer may, in other words, replicate a private association between musical patterning and verbal concepts in his or her works which remains inscrutable to the wider musical community.

7. The Transmission and Mutation of Musical Memes

The center of our theoretical models is the concept of transmission: for biologists, and in particular geneticists like ourselves, the centrality of the concept of transmission to evolutionary thinking is patently obvious. In biological material, however complex, there exists an almost perfect mechanism of genetic transmission. Evolution is the result of mutational exceptions to perfect transmission and the differential success of the products of this imperfect transmission. (Cavalli-Sforza and Feldman 1981: 341)

In cultural material, the "mechanism of transmission" is less perfect than is the case with biological material and, as a result, the "mutational exceptions to perfect transmission" are more numerous. These deficits in copying-fidelity are thus intrinsic to all replicants, but are a particular propensity of the meme; the parlor game of 'Chinese Whispers' represents this process in isolated and compressed form. The tendency towards miscopying makes available memes which are variants of existent forms - i.e., mutations - and which are subject, as are all memes, to the pressure of 'cultural selection', the analogue, proposed by Cavalli-Sforza and Feldman, to the natural selection which regulates the replication of genes within living systems.

They define this as

...the rate or probability that a given innovation, skill, type, trait, or specific cultural activity or object - all of which we shall call, for brevity, *traits* - will be accepted in a given time unit by an individual representative of the population. (1981: 15)

Like natural selection, cultural selection works upon the totality of memes (traits, in the terminology of Cavalli-Sforza and Feldman) within a cultural community and leads to their

differential replication. That is, if a meme arises which is a clear variant of an existing meme it may persist and increase its representation or it may become extinct, according to whether it is more or less susceptible to imitation as a result of the changes it has undergone. The net result of this process of cultural selection is change in the relative frequency of memes in the meme pool over time. The concept of susceptibility to imitation is directly analogous to the biological notion of reproductive fitness; it is an index of the replicant's capacity for replication which Cavalli-Sforza and Feldman term 'cultural fitness' (1981: 17). In biological replication, a gene's fitness is contingent upon the phenotypes it plays a role in engendering. In cultural replication, an analogous situation obtains, for a meme is not selected directly; rather, it is selected by virtue of its phenotypic consequences. [Note 32]

Figure 9 represents the processes of memetic transmission and mutation schematically. Because cultural products are transmitted from a producer to a receiver via an intermediate (phenotypic) form, one means of representing the process is to adapt the Molino/Nattiez notion of the *semiological tripartition* (Nattiez 1990: 10 ff.). The figure traces the movement of memes as they pass between the *poietic*, *neutral*, and *esthetic* levels and across the somatic-extrasomatic boundary which bisects the diagram. [Note 33] Five individuals, or hosts, are shown; these individuals, 1-5, need not be in immediate geographical or chronological relationship with each other, although they often are:

Here meme *M*, shown located in the brain of the first host, 1, is situated at the poietic level and, initially, exists in somatic form. The process of conversion into the extrasomatic form, a musico-graphical or musico-aural version, first moves the meme across the somatic-extrasomatic boundary (the vertical line bisecting the diagram) within the poietic level - at this stage the meme may exist in the context of compositional sketches and drafts - and then across to the neutral level, where the meme exists as part of a completed, notated (or even improvised) composition. The second host, 2, initially encounters the meme from the standpoint of the esthetic level, either by hearing the meme in its musico-aural form or by seeing the meme in its musico-graphical notation. The movement from the esthetic back to the poietic level within the second host corresponds broadly to the two principal stages of memetic transmission identified by Cavalli-Sforza and Feldman: *awareness* followed by *adoption* (1981: 62-65).

Once the adoption stage is accomplished, meme *M* now resides in the brains of both the first and second hosts and may then be transmitted to other hosts. Of course, a meme is never imitated with complete accuracy over any length of time; some changes, albeit very slight, are almost inevitable during this process. As the diagram shows, a third host, 3, might encounter *M* and subject it to alteration at some stage in the course of its progress through the sectors esthetic-somatic (awareness), poietic-somatic (adoption), poietic-extrasomatic (compositional sketches), and finally neutral-extrasomatic (the musico-graphical and/or musico-aural phenotypic form). The sectors of the diagram within which mutation can occur are indicated by dotted brackets. The changes imposed on *M* might be *intentional*, *accidental*, or indeed *obligatory*. In the latter case, this is determined by the new context into which the meme must be inserted, for memes, as has been seen in Section 6.1, are rarely transmitted singly but as components of larger memeplexes.

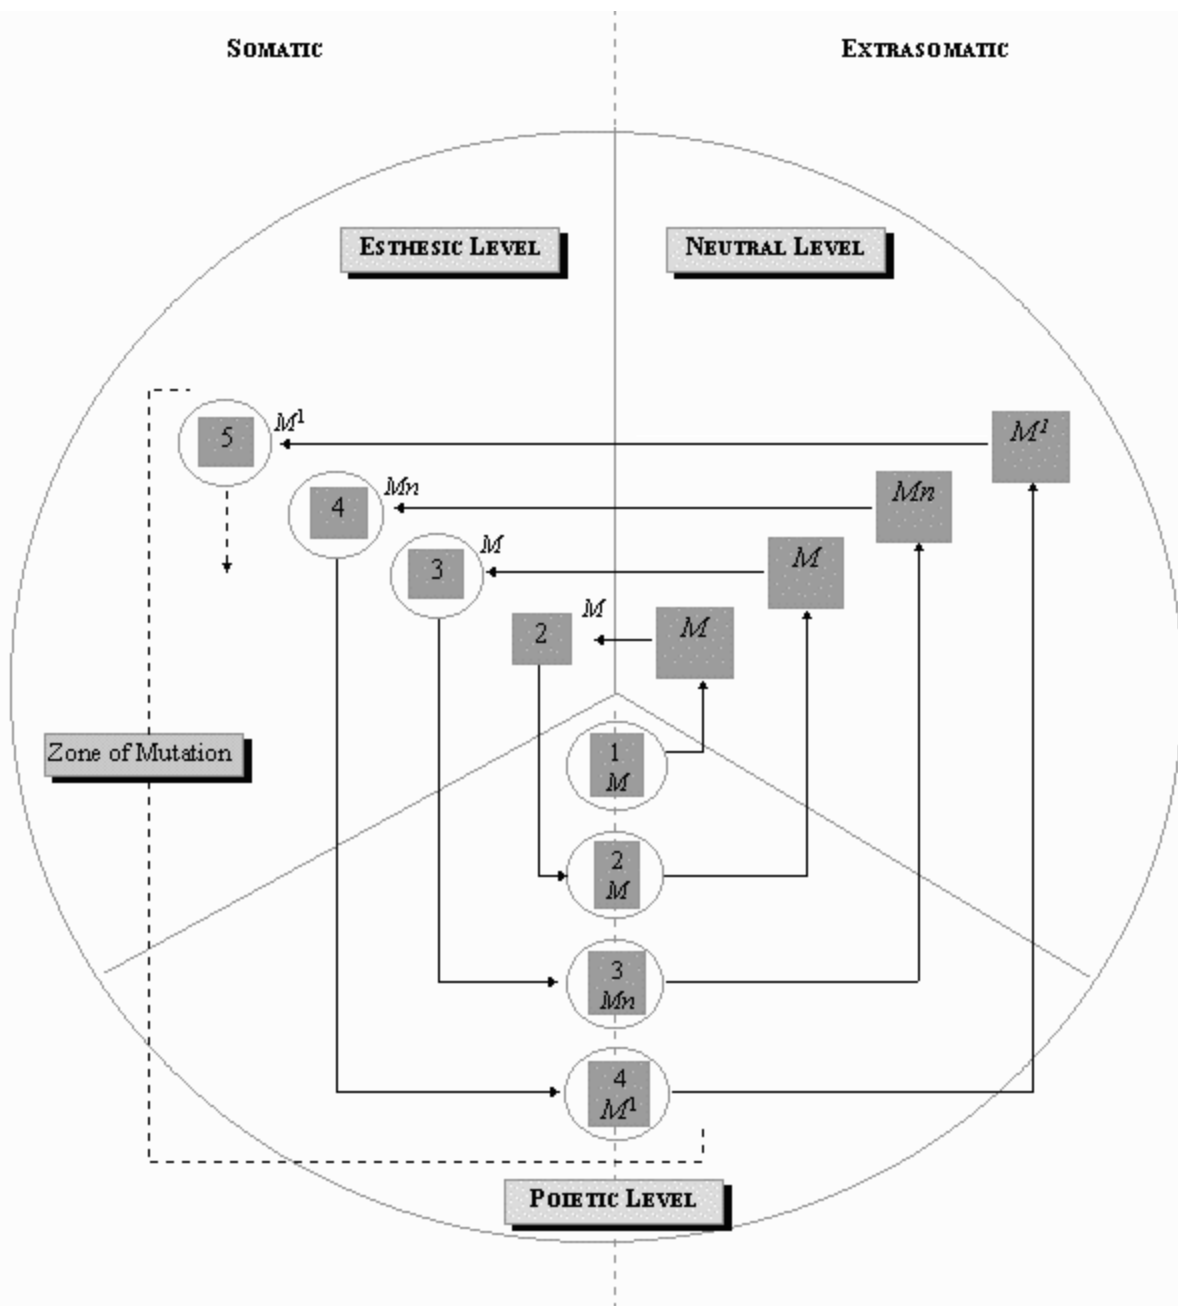

Figure 9: Memetic Transmission and Mutation and the Three Levels of the Semiological Tripartition

At its inception, the mutant is a mnemon, Mn , rather than a meme, for if a particle defined as or assumed to be memetic gives rise to a mutant form, the mutant, at its moment of genesis, is not memetic; at this moment it is theoretically unique, unimitated. When the mnemon is copied into the brain of a subsequent host - 4 in Figure 9 - the particle attains memetic status, as meme M^1 . The mutant form may *overwrite* the original meme in the brain of the third host or coexist with it. It may even be (re-)encountered by the first and second hosts and copied into their brains,

possibly overwriting the original copies of *M* or coexisting with them. As Figure 9 shows, meme *M*¹ is then subject to further imitation, and possible mutation, by a fifth host, 5, and subsequent hosts *ad infinitum*.

This account hopefully makes clear that, whereas the gene is propagated non-phenotypically (ultimately genes, not bodies and other gene products, reproduce themselves), the meme, of necessity, must be propagated phenotypically. To recall Blackmore's terminology cited in Section 4.1, memetic propagation is an example of "copy-the-product," as opposed to the "copy-the-instructions" of genetic transmission (1999: 61).

8. The Evolution of Musical Style

It is perhaps true to say that the central achievement of *The Selfish Gene* was to recast an old argument in evolutionary biology in the most radical and striking terms, and in so doing breathe new life into the New Synthesis. Biologists have long debated the question of the level at which natural selection operates - the 'units of selection' issue. Does it operate at the level of the species (i.e., are species selected for survival or extinction *en bloc*); at the level of the group within a species (i.e., is the group favored at the expense of the larger collective); or at the level of the individual organism (i.e., is the species simply a useful term for discussing a collection of genetically and morphologically similar but functionally independent agents)? Dawkins dismissed all of this, insisting that ... the best way to look at evolution is in terms of selection occurring at the lowest level of all...the fundamental unit of selection, *and therefore of self-interest*, is not the species, nor the group, nor even, strictly, the individual. It is the gene, the unit of heredity. (1989a: 11; my emphasis)

Given that the principle of Universal Darwinism holds that these remarks must be taken to apply analogically to all replicators, the same considerations must be applied to memetics. Thus, the single unit meme is the fundamental unit of selection, and not any larger configuration. Without wishing to labor analogies between genetics and memetics, it is nevertheless interesting to note that Meyer's hierarchical view of cultural structure outlined in Section 3 maps fairly neatly onto the biological hierarchy Dawkins describes, helping us to comprehend more clearly the implication of the unit of selection principle to musical memetics:

NATURE	CULTURE
Species	Dialect
Group of Organisms	Idiom/Genre/Formal-Structural Type
Individual Organism	Work
Gene	Meme

Table 2: Correspondences between Natural and Cultural Hierarchies

Here, the cultural analogue for the species may be taken to be the dialect; a group of organisms within the species can be compared with either the composer's personal style, with a musical genre (such as the symphony, the string quartet, or the opera), or with a formal-structural type (such as those considered in Section 6.2); and the individual organism maps onto the self-contained musical work, the individual representative of a genre. Lastly, the memes whose

phenotypic products constitute a musical work are analogous to the genes whose phenotypic products constitute the individual organism.

It is, of course, intuitively clear that the meme is the unit of selection in the evolution of musical style: whole dialects, such as the Austro-German Classical style, are not selected for or against; neither are the styles of composers, musical genres, or formal-structural types; and neither are whole works. What are selected are the memes which constitute those works. In this view, cultures evolve from the bottom up, not the top down, the nature of the system being a function of the properties of the units at the lowest hierarchic level.

In the evolution of musical style, a mutant meme appears in the work of a composer, the level of intraopus style, by means of the processes discussed in Section 7. Providing it possesses high longevity, fecundity, or copying-fidelity, it may then be copied in other works of that composer, thereby moving to the level of idiom. Further imitation might disseminate the meme among the composers in a community, taking it to the level of the dialect, the configuration of the which is slowly and subtly changed.

However, it is the case, as Gatherer observes apropos the evolution of jazz, that New memes, such as novel chord patterns, rhythmic changes, or alterations in instrumentation are subject to scrutiny as to how they cohere with the pre-existing whole. Sudden innovation is not permitted but small innovations may cumulatively have large results. (1997: 80)

This point is developed by Dawkins in a passage in which the word 'meme' may be substituted for 'gene' throughout. He asserts that

The gene pool will become an *evolutionarily stable set* of genes, defined as a gene pool that cannot be invaded by any new gene. Most new genes that arise, either by mutation or reassortment or immigration, are quickly penalized by natural selection: the evolutionarily stable set is restored. Occasionally a new gene does succeed in invading the set: it succeeds in spreading through the gene pool. There is a transitional period of instability, terminating in a new evolutionarily stable set - a little bit of evolution has occurred....Progressive evolution may be not so much a steady upward climb as a series of discrete steps from stable plateau to stable plateau. It may look as though the population as a whole is behaving like a single self-regulating unit. But this illusion is produced by selection going on at the level of the single gene. (1989: 86)

The notion of the *evolutionarily stable strategy* (ESS), formulated by J. Maynard Smith, is a concept fundamental to understanding cultural evolution. In biological evolution, an ESS is essentially a behavioral strategy which, "...if most members of a population adopt it, cannot be bettered by an alternative strategy," "[a] strategy that does well in a population dominated by the same strategy" (Dawkins 1989: 69; 1983a: 286). Many patterns of animal behaviour, including aggression and territoriality, in which the conflicting self-interests of the members of a group reach an equilibrium, are understandable in terms of this notion. Individuals deploying deviant strategies against the majority strategy generally cannot better it, and they and their strategies are consequently penalized by natural selection.

In cultural evolution, the ESS may be understood as an index of the resistance of a meme pool to incursions by mutant memes. However, because the meme "...is already achieving evolutionary change at a rate that leaves the old gene panting far behind" (Dawkins 1989: 192), even a year of memetic evolution is comparable to many millions of years of genetic evolution. Consequently, the generation and propagation of mutant memes, and the resultant motion from "stable plateau to stable plateau" as one ESS is supplanted by another, occurs at a rapid, and probably indistinguishable rate. This process is represented, in simplified form, below:

Figure 10: Successive Evolutionarily Stable Strategies

Acceptance of this perspective forces one to question Meyer's notion of dialect, which he defines as "...substyles that are differentiated because a number of composers...employ (choose) the same or similar rules and strategies" (1989: 23). This differentiation may be on the basis of geography, nationality, cultural movements, social class, or function within the culture; "...but most often dialects are distinguished historically" (1989: 23). From this one might interpret the period *c.* 1700-*c.* 1900 as comprising three historical dialects, the Baroque (the period of Bach and Handel), Classicism (the period of Haydn, Mozart, and Beethoven), and Romanticism (the period of Schumann, Wagner and Brahms), operating within the constraints of a single set of rules, that of tonality. Yet whilst no musicologist would claim a strict articulation between these periods, if one regards the evolution of musical style as driven by a fluid meme pool configuring itself into a succession of transient ESSs, then the notion of discrete historically distinguished dialects cannot logically remain tenable. The meme pool of Bach's time evolved through a near infinity of ESSs until it became transmuted into that of Brahms'.

Moreover, skepticism is needed concerning the rigidity of the distinction Meyer draws between diachronic changes from one dialect to another, which he terms *trended* changes (for example, between Classicism and Romanticism, which occurred *c.* 1800-*c.* 1820); and changes from one system of rules to another, which he terms *mutational* changes [note 34] (for example, between tonality and serialism, [note 35] which occurred *c.* 1900-*c.* 1920). He conceives this distinction as one between differences of degree and kind respectively, asserting that the two modes of style

change are not necessarily related (1989: 102), and suggesting that "[i]t does not follow...that the trend *caused* the mutational change, only that the stylistic/cultural situation created by the trend made it possible for the mutation to endure - be replicated....Nor is it supposed that if a stylistic consensus takes place, the new rules (mutations) will be a result of prior trends or strategies" (1989: 103, notes 79, 80).

Whilst there is no teleological inevitability of a given rule change's arising from antecedent changes in the dialect(s) it encompasses, it must be the case - accepting the bottom-up perspective of memetic evolution - that the large-scale reconfiguration represented by a change in rules can only be defined in terms of the changes occurring upon lower hierarchic levels. A neo-Darwinian, meme-selectionist perspective would regard mutational changes as the inexorable outcome of cumulative trended changes, the latter acting not only as a necessary condition for the former but also as determinants of the configuration of the new higher-order system. In this respect, cultural evolution again parallels biological evolution, for "...all sane Darwinians are gradualists in the extreme sense that they do not believe in the *de novo* creation of very complex and therefore statistically improbable new adaptations like eyes. This is surely what Darwin understood by the aphorism 'Nature does not make leaps'" (Dawkins 1983a: 287-288). [Note 36]

Lastly, just as the notion of distinct, historically sequential dialects is undermined by a view of musical style as a succession of transient ESSs, so the idea of distinct, historically sequential systems of rules cannot logically be sustained. Whilst the division of style along the vertical (synchronic) axis of rules, dialects, and idioms is a useful intellectual tool for structuring a complex field, retaining its clarity at any given point in musical time, when considered in association with the horizontal (diachronic) axis representing temporal progression its categories of rules and dialects are ultimately blurred by the inexorable, random gradualism of memetic mutation.

9. Conclusion: Towards a Memetics of Music

Given the great complexity of the subject it addresses, this article has only scratched the surface of what might constitute a memetics of music. I hope, nevertheless, to have outlined a number of what I see as fundamental points which, in conclusion, are now briefly reviewed.

Whilst commentators such as Dawkins and Dennett have seen musical memes as, to re-employ the linguistic analogy, comparable with sentences, I have attempted to show that they are more akin to the individual word - that music is made up of small units of pitch and rhythm which, by virtue of their replication, should be regarded as memetic.

The examples have illustrated that music is a rich field of interacting parameters, some of which are capable of sustaining memetic replication. Whilst I have largely confined myself to the parameter of pitch, in common with the practice of much analytical musicology, a comprehensive memetics of music must account for these individual parameters and, more importantly, their interaction in the form of parametric memeplexes.

In the realm of pitch, music, perhaps more than any other symbolic system, sustains the propagation of memetic structures at a variety of hierarchic levels, from its immediate surface to

more remote levels. At the deepest levels of structure are propagated structural memes, the superordinate configurations repeatedly reinstated by composers as the guiding architectural frameworks of their compositions. The analytical method of Schenker is an effective, although by no means unproblematic, method of representing these structures. Whilst not discussed here, it seems the case that rhythmic memes are similarly propagated at several hierarchic levels - a subject to which Yeston 1976 is addressed, although not in terms of the memetic paradigm. I hope to have shown that, as with all cultural evolution, the evolution of music occurs because of the differential selection and replication of mutant memes within idioms and dialects. Slowly and incrementally, these mutations alter the memetic configuration of the dialect they constitute. Whilst gradualistic, this process eventually leads to fundamental changes in the profile of the dialect and, ultimately, to seismic shifts in the overarching principles of musical organization, the rules, propagated within several dialects.

Finally, I hope to have indicated that the application of musicological insights to memetics and the memetic paradigm to musicology offers considerable benefits to both areas of inquiry. To memetics, music offers a field of study in which the units of selection are, arguably, clearer and more amenable to analysis than verbal text- and concept-based memetics. To musicology, memetics offers a new viewpoint on its concerns, one which has the power to unify a variety of disparate musical subdisciplines - composition, performance, improvisation, listening, notation, theory and analysis, history and criticism, musical style and style-history, music-psychology, aesthetics and philosophy, and influence [note 37] - under the cool logic of a neo-Darwinian, meme-selectionist perspective.

Notes

1. One might qualify Dennett's assertion by noting that for any substrate there is a limited set of algorithms it can instantiate. Moreover, substrates vary in their ability to carry out an algorithm; there is a continuum of efficiency between a set of substrates that are able to carry out the algorithm and a set that are not. A nonarbitrary relationship therefore exists between the logical structure of an algorithm and the materials that instantiate it. It is, of course, my proposition that the algorithm of evolution by natural selection *is* one music instantiates well, a claim for which this paper is hopefully seen as offering evidence.
2. The various strands constituting the discipline of musicology are surveyed in Kerman 1985.
3. Gatherer's (1997) contribution to the development of a memetics of music is acknowledged. A longer treatment of the subject of musical memetics than the present article may be found in my forthcoming article 'The Selfish Meme: Particularity, Replication, and Evolution in Musical Style' (2000). A few paragraphs in the present article, particularly in Section 8, are adapted from 'The Selfish Meme.'
4. Constraints of space prevent the discussion of music outside the western European art canon. Traditional and popular musics are, I believe, readily amenable to examination in memetic terms, although arguments presented here involving notation are not always pertinent to non-western musics, in which graphical fixation often plays little or no role. This is partly a consequence of

the fact that the western trichotomy between composer, performer, and listener is rarely so sharply drawn in non-western musics.

5. See Scruton 1997: Chapter 7 for a detailed examination of the relationship between music and language.

6. The works of Beethoven (1770-1827), for instance, are generally divided into three style-periods, albeit with very fuzzy boundaries at *c.* 1803 and *c.* 1815.

7. Modality is the organization of the seven pitches C, D, E, F, G, A, and B into a number of different scale patterns, each with its own distinctive internal intervallic (i.e., pitch spacing) pattern. It was the system of pitch organization employed during the Medieval (*c.* 500-*c.* 1450) and Renaissance (*c.* 1450-*c.* 1600) periods, but has its origins in the music of ancient Greece.

8. Tonality is the organization of the twelve pitches of the chromatic scale into a hierarchy centered around one note, the *tonic* or *key-note*. It was the system of pitch organization employed during the Baroque (*c.* 1600-*c.* 1750), Classical (*c.* 1750-*c.* 1820), and Romantic (*c.* 1820-*c.* 1900) periods. Boundaries between these periods, and between modality and tonality and between tonality and serialism (see note 35), are, for reasons discussed in Section 8, highly fluid.

9. The concept of *topic* referred to in this Figure is examined in Section 6.4.

10. Sereno 1991 offers a stimulating critique of interdisciplinary analogy.

11. A now-defunct game show featured a competition ('Name that Tune') between two finalists to name a well-known melody, the contestants gambling on being able to name the melody on hearing only a few of its notes, within a range of one to seven. Some, I believe, were able to name melodies having heard as few as the opening two notes. Accepting the element of fortune here, and the fact that the themes were played fully harmonized, some melodies clearly begin with distinctive three-note memes.

12. Abbreviations used in musical examples in this article are as follows: b. N = bar N; bb. N-N = bars N-N inclusive; I, II, etc. = movement number of a multi-movement work.

13. The up and down arrows and associated integers indicate the direction of melodic movement and its size in semitones (the octave, in western music, is divided into 12 semitones). It seems logical to suggest that intervallic structure, in addition to absolute pitch location, should be a criterion in the establishment of memetic equivalence classes. On this principle, the opening gesture of 'Misty' could be represented, independently of key, as $\downarrow 3 \downarrow 5$.

14. In many of the examples here, particularly Example 8, I have transposed pitch memes from passages in different keys into one key in order to facilitate comparison, but it is worth noting that a given meme in two different keys is essentially the same meme, in that, by definition, it retains its internal intervallic structure; what differs is the absolute pitch location.

15. In the passage from the 'Trout' Quintet, *me* appears in the key of A major, whereas in the Beethoven symphony it appears in C major, at the point where the melody modulates from the tonic (home) key of A minor to C, its *relative major* (i.e., the major key with the same *key signature*).

16. Distributional analysis is a method of analyzing music developed by musical semiologists such as Jean-Jacques Nattiez and Nicolas Ruwet in which, as with the analysis of language, music is segmented into its component phonetic units (*paradigmatic analysis*) and then the syntactical (grammatical) distribution of those units is determined (*syntagmatic analysis*).

17. The minuet movement of a Classical multi-movement work (such as a symphony or a string quartet) is tripartite, consisting of the minuet proper, a central *trio* section (i.e., a contrasting minuet), and a closing repeat of the minuet.

18. The 'parametric complex' discussed in Section 5.1 is, of course, a memplex composed of elements in different parameters; that considered here exists in only one parameter, that of pitch.

19. In the 1920s and 1930s Schenker developed a theory which conceived music as consisting of three interrelated levels (*Schichten*): the *foreground* (*Vordergrund*), the immediate musical surface; the *middle ground* (*Mittelgrund*), a deeper level revealed by the removal of superficial, decorative notes; and the *background* (*Hintergrund*), the most remote and fundamental level. Forte and Gilbert 1982 and Neumeier and Tepping 1992 are good introductions to his thinking, presenting the essence of Schenker's seminal work, *Der freie Satz* of 1935 (1979), in accessible form. The following Schenkerian conventions are adopted here: the degrees of the scale are indicated using Arabic numerals topped by the caret symbol ($\hat{1}$, $\hat{2}$, $\hat{\sharp 4}$, etc.); and important harmonic steps (*Stufen*) are indicated by Roman numerals (I, IV, V, etc.).

20. A *linear progression* (*Zug*) is a stepwise melodic motion generally spanning the intervals (gaps) of a third, fourth, fifth, sixth, or octave. The forward slash, in Schenkerian analysis, indicates both vertical alignment and structural synchrony. Thus, $\hat{5}/\hat{1}-\hat{4}-\hat{3}$ means that whilst the tonic (I) chord is operative, the scale degree $\hat{5}$ is sounded, followed by the descending motion $\hat{5}-\hat{4}-\hat{3}$. In an *interruption* (*Unterbrechung*) - symbolized by "||" - the upper line descends to $\hat{2}/\text{V}$ and then returns to the pitch from which it began its descent. This is then followed by a second descent which reaches the $\hat{1}/\text{I}$ averted by the interruption.

21. Schenker proposed that all tonal pieces could ultimately be reduced to one of three *Ursätzen*, or *fundamental structures*. The *Ursatz* is a two-part structure, consisting of a lower voice or *Bassbrechung* (*bass arpeggiation*) outlining the harmonic progression I-V-I, and an upper voice or *Urlinie* (*fundamental line*), expressing the linear progression $\hat{8}-\hat{7}-\hat{6}-\hat{5}-\hat{4}-\hat{3}-\hat{2}-\hat{1}$, or $\hat{5}-\hat{4}-\hat{3}-\hat{2}-\hat{1}$, or $\hat{3}-\hat{2}-\hat{1}$. It will be realized that the three *Ursätzen*, repeatedly reinstated by a variety of foreground and middle ground memes, are memes at the deepest levels of musical structure (see Section 6.2 for further treatment of this concept). A memetic view of musical structure tends, however, to overturn Schenker's view that "...all the foreground diminutions, including the apparent 'keys' arising out of the voice-leading transformations [of the middle ground], ultimately emanate from the diatony [i.e., the *Ursatz*] in the background" (1979: 11). Instead of this *top-down* perspective, memetics suggests the *bottom-up* generation of middle ground

structures by patterning at the foreground and, in turn, the generation of background structures by middle ground events.

22. From this discussion, it will be understood that 'Schenkerism' is a rich memeplex of musical and extra-musical memes fronted by a set of graphical memes. As such, one must be aware that it filters, and inevitably colors, the memes that make up the music which is its subject and with which it interacts. In other words, the view of musical structure one formulates via Schenkerian analysis is, possibly, as much an artifact as those distortions which sometimes result from the treatment of samples in preparation for electron microscopy. Throughout this article, my reliance on Schenkerian memes is a testament to their virulent infective powers; no other comparable music-analytical memeplex has such high fecundity at present. Nevertheless, I am fortunately also a host to other memes which impart to me some degree of critical detachment, and I hope the reader is likewise infected. For vigorous arguments *contra*-Schenker, see Narmour 1977.

23. See Meyer 1989: 50-54 for a consideration of such schemata, which "...are patterns that, because they are congruent both with human perceptual/cognitive capacities and with prevalent stylistic (musical and extra-musical) constraints, are memorable, tend to remain stable over time, and are therefore replicated with particular frequency" (1989: 51). Meyer also uses the term *archetype* to refer to structural classes which are the result of innate rather than learned responses; in practice the distinction is often difficult to draw (Gjerdingen 1988: 46 f.).

24. For a comprehensive survey, see Bent and Drabkin 1987, Chapters 2 and 3; see also note 22.

25. It is worth observing that in distinguishing between the process of memetic conglomeration which gives rise to the individual work of art and the long process by which the structural archetype instantiated by that work evolves, we mirror the clear biological parallel between *ontogeny* - the (embryonic) development of the individual organism - and *phylogeny* - the development of the species of which the organism is, in a sense, an instantiation.

26. Binary form consists of two repeated sections, the first of which (A) moves from the tonic key to a contrasting key, the second (B) from this contrasting key back to the tonic. Ternary form consists of three sections, the first (A) being a closed unit, the second (B) offering a strong contrast, and the third being either identical to A or a modified version (A¹) of A. Sonata form may be understood as an evolutionary descendant of binary form in which the B section of the binary form becomes divided into two distinct phrases, the second of which *recapitulates* the A part of the form (A | B A¹). This summary is, however, highly oversimplified: see Rosen 1988 for a full discussion of the relationships between eighteenth-century binary forms and sonata forms.

27. A normative prolongational structure is "...specified in terms of relationships of prolongational connection among structurally significant events, not in terms of any specified sequence of events" (Lerdahl and Jackendoff 1983: 248).

28. Constraints of space prevent my addressing the burgeoning neuro-scientific literature on music, central as this will be to further research in musical memetics. See, especially, Bharucha 1999, in which a neural net model of musical organization is examined. Such models "...have a

number of properties that recommend them as models of music cognition....they can account for how we learn musical patterns....their assumptions are either known or plausible principles of neuroscience....they are capable of recognizing varying shades of similarity and are therefore well suited to modeling similarity-based accounts...of tonality or modality....[and] they can discover regularities in musical styles that may elude formal music-theoretic analysis..." (1999: 413). Moreover, "...a neural net can learn temporal composite patterns so that they function as schemas and as sequential memories" (1999: 424).

29. The particular signifier 'dominant seventh chord' would, of course, be propagated principally in the brains of Anglophones. Owing to language differences, the same signified musical meme would have been associated with different signifying concept memes in the brains of, for instance, Mozart, Rameau, and Vivaldi.

30. This account clearly oversimplifies matters considerably by ignoring the motor-control memes which govern the muscular actions engendering writing, speaking, and the production of musical sounds.

31. Another example is the coadaptation between the rhythmic meme ♩ ♪ ♪ ♪ (seen in Example 2 i and iii, where it is labeled meme *y*) and verbal-conceptual memes articulating notions of pompous militarism.

32. To speak of a single gene's or meme's fitness is somewhat artificial: these replicators are selected and propagated as complexes and exert their pheno/phemotypic effects in concert. A given pheno/phemotypic effect may be engendered by several genes or memes; conversely, several effects may be brought about by a single gene or meme. To use terms from population biology, musical memes would appear to be subject to *r*-selection, which is "[s]election for the qualities needed to succeed in unstable, unpredictable environments..." (Dawkins 1983a: 293). *K*-selection, by contrast, is "[s]election for the qualities needed to succeed in stable, predictable environments..." (1983a: 288).

33. Nattiez defines these three levels as follows: "(a) *The poietic dimension*: even when it is empty of all *intended* meaning...the symbolic form results from a *process of creation* that may be described or reconstituted. (b) *The esthetic dimension*: 'receivers,' when confronted by a symbolic form, assign one or many meanings to the form.... (c) *The trace*: the symbolic form is embodied physically and materially in the form of a *trace* accessible to the five senses. We employ the word *trace* because the poietic process cannot immediately be read within its lineaments, since the esthetic process...is heavily dependent upon the lived experience of the 'receiver.' Molino proposed the name *niveau neutre* [neutral level] or *niveau matériel* [material level] for this trace" (1990: 11-12; his emphases).

34. Meyer is using the term *mutational* in a different sense to that used in this article: a memetic standpoint regards *trended* changes as just as much the result of mutations as *mutational* changes.

35. Serialism is the organization of the twelve pitches of the chromatic scale into a relationship of equal status. It is a system of organization developed by Arnold Schoenberg (1874-1951) by the early 1920s and employed in the works of many later twentieth-century composers.

36. Thus, whilst many commentators see the appearance of the serial system as a revolutionary change, in the gradualist interpretation advocated here it is an evolutionary transformation grounded in antecedent developments, particularly the steady attenuation of tonality in the decades after Wagner's *Tristan und Isolde* (1865), and its eventual disintegration into "free atonality" in the works of progressive composers c. 1910.

37. Studies of influence - now often subsumed under Kristeva's term *intertextuality* (1969) - in music, such as Korsyn 1991 and those sources listed in his note 5, are increasingly common in the musicological literature. To my knowledge, however, none invokes the memetic paradigm.

Acknowledgements

My thanks are extended to Dr. Yo Tomita of Queen's University Belfast for the use of his *Bach* musicological font. The *Bach* website is at <http://www.music.qub.ac.uk/~tomita/bach-mf.html>. The music examples were set using *Sibelius* by Ian Phillips-Kerr at *MusicWorks* (ipk@musicworks2000.freeserve.co.uk).

Abstract

The science of memetics aims to understand the evolution of socially transmitted cultural traits. Recently attention has focused on the interaction between memetic and genetic evolution, a phenomenon described as meme-gene co-evolution. Whether cultural evolution occurs purely at the level of the meme, or through meme-gene interaction, a body of formal theoretical work already exists that can be readily employed to model empirical data and test theoretical hypotheses. This is cultural evolution and gene-culture co-evolutionary theory, a branch of theoretical population genetics (Cavalli-Sforza & Feldman [6]; Boyd & Richerson [3]; Feldman & Laland [12]). We reject the argument that meaningful differences exist between memetics and these population genetics methods. The goal of this article is to point out the similarities between memetics and cultural evolution and gene-culture co-evolutionary theory, and to illustrate the potential utility of the models to memetics. We illustrate how the theory can be applied by developing a simple illustrative model to test a hypothesis from the memetics literature.

Keywords: brain size, cultural evolution, gene-culture co-evolution, meme, memetics

1 Introduction

Memetics endeavours to understand culture in terms of the evolution of socially transmitted cultural traits. Recent instantiations have acknowledged that memetic and genetic evolution can interact in rich and complex ways, a phenomenon described by Blackmore [2] as "meme-gene co-evolution". Memetics has developed in virtually complete isolation from a related discipline with very similar concerns, namely, cultural evolution and gene-culture co-evolution. Cultural evolution is a branch of theoretical population genetics established in the early part of the 1970s, and dedicated to using population genetics models to investigate the evolution and dynamics of cultural traits equivalent to memes. Gene-culture co-evolution employs the same methods to explore the co-evolution of genes and cultural traits. Whether meme evolution occurs exclusively at the cultural level, or through meme-gene interaction, a body of formal theoretical work already exists that can be readily employed to model empirical data and test theoretical hypotheses (Cavalli-Sforza & Feldman [6]; Boyd & Richerson [3]; Feldman & Laland [12]). The goal of this article is to point out the parallels between the logic and assumptions of memetics and cultural evolution/gene-culture co-evolutionary theory, and to illustrate the potential utility of the models to memetics.

We begin by pointing to the similarities between memetics and cultural evolution theory. Both

disciplines explicitly assume that at least some aspects of human culture can be broken down into discrete traits, or component elements, henceforth memes (although both approaches have also explored the evolution of continuous traits). Both disciplines believe that memes can increase or decrease in frequency through the processes of Darwinian evolution (i.e., the differential survival and reproduction of individuals), as well as through similar or analogous processes affecting cultural selection (i.e., the differential survival and reproduction of memes). Both disciplines stress that memes should be treated as replicators in their own right, and most proponents of each would probably accept that the adoption of at least some memes is not independent of the individual's genotype. We suspect that most advocates of the population genetics approach would be sympathetic to the argument that many of the dynamics of contemporary human culture are best understood at the level of the meme. The allocation of parameters to describe rates of cultural transmission in cultural evolution and gene-culture co-evolution models is formally equivalent to treating cultural transmission based on cultural replicators that are distinct from genes (Feldman & Cavalli-Sforza [10]; Cavalli-Sforza & Feldman [6]). We also suspect that many memeticists would be sympathetic to Feldman & Laland's [12] claim that much human evolution over the last 2 million years can be best understood as gene-culture (or meme-gene) co-evolution. Indeed the basic philosophy and parallels between the two approaches are so similar, it is striking that they have not converged.

We suggest that there are two main reasons why memetics has not yet embraced cultural evolution, neither of which is of sufficient validity to warrant their continued divergence. The first reason is that cultural evolution and gene-culture co-evolutionary theory are relatively small and specialized branches of population genetics, with a lot of the research published in highly-rated yet somewhat esoteric journals, and containing material of an extremely technical and mathematical nature, but which rarely adopts the term meme, or refers to the memetics literature. As a result of this, many meme enthusiasts are simply unaware of this population genetics literature, and among those that are, many find it difficult to comprehend. This article is written with the belief that these technicalities and linguistic differences should not be allowed to drive a wedge between two disciplines that otherwise have such similar goals, and for which the opportunities for cross-fertilisation of ideas and methods are considerable. It is quite clear that memetics as a discipline is not at all hostile to theory, and that many meme enthusiasts are sufficiently mathematically sophisticated to understand the theoretical papers. One of the goals of this paper is to introduce cultural evolution methods to a memetics audience.

A second reason why memetics has distanced itself from cultural evolution theory is the belief among meme enthusiasts that advocates of cultural evolutionary theory assume genes or genotypes to control the adoption and transmission of memes. To use Lumsden and Wilson's [17] metaphor, memeticists think that cultural evolutionists believe memes are on a genetic leash. This is not the case. Although Lumsden and Wilson used the terms cultural evolution and gene-culture co-evolution, their work had more in common with the earlier sociobiologists than with modern cultural evolution and gene-culture co-evolutionary theory. The population genetics approach to culture grew out of a rejection of sociobiology. This rejection stems, in part, from sociobiology's failure to take cultural transmission seriously, or to recognise that not all cultural traits are to the ultimate benefit of the genes. Cultural evolution and gene-culture co-evolutionary models have developed a system of formalism that allows for leashes of variable length, ranging from extremely tight genetic control, to no meaningful genetic influence at all (see Feldman &

Laland [9], for a discussion of this issue). The models do this by allocating parameters that determine the probability that an individual will acquire a particular meme that may, or may not, differ according to the individual's genotype. Moreover, gene-culture co-evolutionary theory has long explicitly asserted that the leash tugs both ways, and that under some circumstances genes can be under cultural control (Feldman & Cavalli-Sforza [10]; Feldman & Laland [9]). If contemporary practitioners of gene-culture co-evolutionary theory no longer ask Dennett's [7] *Cui bono?* question, it is because two decades earlier they developed their own method of answering this question, namely, the *phenogenotype*. We describe how phenogenotypes can be used to explore meme-gene co-evolution below. For the moment it is sufficient to note that there is nothing in cultural evolution theory that precludes cultural adaptations "for the good of the meme", or a "meme's-eye-view" approach.

We reject the argument that meaningful differences exist between memetics and the population genetics methods. We also believe that cultural evolution and gene-culture co-evolutionary theory will be much enriched by embracing memetics. *Prima facie* complex social phenomena, for example, institutions or belief systems, may be treated as memeplexes made up of a plethora of attributes, many of which are memes in their own right, each with varying distribution and dynamics (Plotkin [18]; Blackmore [2]). Social anthropologists limit their ability to carry out predictive and comparative analyses, by insisting on an all-encompassing, holistic approach, rather than breaking culture down into manageable units, and performing rigorous quantitative analyses. We do not refute the idea that the distributions of cultural traits may be complex, but suggest that real progress can be made by addressing those cultural traits that have manageable, easily identified and quantifiable distributions. In the case of our worked example, imitate the imitators, we are interested in the presence or absence of a particular cultural trait, therefore it is appropriate to consider discrete memes. Part of the excitement generated by the memetics movement surely reflects the fact that the meme concept by its very existence operationalises culture, breaking it down into the kind of discrete packages that can be subject to scientific enquiry. We believe that mathematical analyses, using cultural evolution and gene-culture co-evolutionary models, can be profitably employed in restricted domains, where cultural traits or memes are easily defined and quantitative studies are possible. We suggest that the techniques of cultural evolution and gene-culture co-evolution can be employed to describe and predict how cultures change, explain current trends in cultural attributes, and test hypotheses concerning the evolution of human behaviour and culture.

2 Introducing an Established Modelling Paradigm

Let us return to Dennett's *Cui bono?* question. Gene-culture co-evolutionary theory has devised its own simple and pragmatic solution to the question of whether genes or memes control cultural (and genetic) change.

Population geneticists recognise that a salient model should be developed at the level of the smallest non-divisible unit, as this is the natural currency by which changes in replicator frequency will occur. For illustration, imagine the co-evolution of two genetic loci subject to natural selection in a population of animals. We will call the loci **A** (with alleles *A* and *a*) and **B** (with alleles *B* and *b*). A two-locus population genetics model would have to track the frequencies of each of the four types of chromosomal combination (*AB*, *Ab*, *aB*, and *ab*), usually

describing them as gametes. The two loci cannot be assumed to be independent because there may be complex interactions or non-random associations between loci, depending on the nature of the selective regime. Subsequent analysis of the system will tell us whether allele A is favoured over allele a , and describe the evolution at the **B** locus. The same applies to gene-culture co-evolution, except here one of the loci (say **B**) contains variants of meme (meme variants B and b) rather than alleles of a gene. The (rather cumbersome) name given to particular combinations of genotype and meme is the phenogenotype. In population genetics models, the genotypes are allocated fitnesses and the rate of transmission is tracked using recursions which describe the frequency of each genotype in terms of the frequencies of genotypes in the previous generation. Likewise, for the gene-culture co-evolutionary model, each phenogenotype is allocated a "fitness", representing its rate of reproduction. However, while genes are transmitted to each individual once a generation, meme transmission is more complex, and may occur on a within-generational timeframe, depending on who acquires the meme from whom. Nonetheless, it is frequently mathematically convenient to track rates of change of phenogenotypes using a generational timeframe. Of course, individuals change their memes frequently throughout their lifetimes, and this will be reflected in changing frequencies of phenogenotypes. In tracing the fortunes of the meme, the model only makes assumptions as to the path of transmission and not the processes that underlie replication. As long as the meme is observable and measurable, analysis of the dynamics of the system can be used in conjunction with empirical data to question the nature of these assumptions, explore the replication process, and test predictions. While there may be nothing directly equivalent to a 'locus' or 'allele' for memes, we believe that sufficient memes compete directly with each other for this to be a useful abstraction.

The gene-culture co-evolutionary framework embraces the full range of selective influences upon the evolution of memes: memetic fitness may be quite independent of genetic influence (there is no genetic leash); memes may influence the fitness of genes (genes are held on a memetic leash); or genetic fitness can determine the success of the meme (memes are held on a genetic leash). For purposes of exposition, we introduce the use of the gene-culture co-evolutionary methods under each of these circumstances.

If cultural inheritance is completely independent of genetic inheritance, that is, if memes are acquired independently of the learner's genotype, then the unit of cultural selection collapses to that of the meme. Under such circumstances, tracking gene frequencies is of no value, gene-culture co-evolutionary methods are inappropriate, and all evolution occurs at the level of the meme. It is here that cultural evolution methods are useful. Cultural evolutionary theory is a modelling paradigm developed by Cavalli-Sforza & Feldman and others to analyse cultural change (Feldman & Cavalli-Sforza [10]; Cavalli-Sforza & Feldman [6]; Boyd & Richerson [3]). This framework has been used to explore phenomena as diverse as linguistics, epidemics, social values and customs, and the diffusion of innovations (i.e. the same subject matter as memetics). Cultural evolutionary models do not use the term meme because they were first developed prior to the publication of *The Selfish Gene*. Instead they use the phrase "cultural trait" or "cultural phenotype". Nonetheless, Cavalli-Sforza and Feldman's methods effectively track changes in meme frequency in a population through cycles of mating, differential social transmission of the meme (cultural selection) and natural selection. The modes of social transmission describe the routes by which memes spread (Cavalli-Sforza & Feldman [6]). Social transmission can occur

vertically (from parents to offspring), obliquely (from parental to offspring generation) or horizontally (within generation transmission), or some combination of these.

Cavalli-Sforza & Feldman define cultural selection as a Darwinian process by which particular memes increase or decrease in frequency due to their differential probability of being adopted by other individuals. In contrast, for these authors natural selection refers to the differential survival of individuals expressing different types of memes. For instance, the spread of contraceptive use through cultural selection processes could alter natural selection pressures induced by sexually transmitted diseases. Therefore the analysis is based on the explicit assumption that cultural traits evolve by Darwinian selection processes, whereby individuals can be selected purely on the basis of their memes. This allows interesting questions to be asked such as, 'Under what conditions might non-adaptive cultural traits evolve?', (Cavalli-Sforza & Feldman [6]). One of the earliest findings to emerge from this analysis is that there are countless circumstances when memes with sufficiently high cultural fitness can increase in frequency despite being maladaptive from a genetic perspective, and decreasing genetic fitness (Feldman & Cavalli-Sforza [10]). Cavalli-Sforza and Feldman's framework also considers cases in which cultural selection operates without affecting Darwinian fitness (e.g. a preference for a particular soft drink).

The models' strengths are in their simple formalization, the ability to predict the frequencies of cultural traits, and the direct applicability to empirically derived transmission coefficients. Cavalli-Sforza and Feldman [6] demonstrated that models can be applied to empirical data, estimating the transmission coefficients for five vertically transmitted traits that would be of interest to meme enthusiasts: salt usage, frequency of praying to God, frequency of swimming, belief in ability versus luck, and political interest. The models can be used to describe patterns of change, make sense of meme variation, extrapolate back into the past to predict past cultural usage, and extrapolate into the future to predict future trends. We have only begun to describe the breadth of cultural evolution models, and countless elaborations and refinements of the methods have emerged, for example, investigating frequency-dependent transmission, the evolution of continuous (quantitative) traits, and the effects of migration, population structure, innovation, and other factors (Cavalli-Sforza & Feldman[6]; Boyd & Richerson[3]; see Laland[15] for a simple introduction).

There are also situations where there is an *interaction* between memes and genes, such that an individual's propensity to adopt a particular meme depends on his or her genotype. This is likely to be more common in investigations of human evolution than in explorations of contemporary human culture. Under such circumstances where there may be meme-gene co-evolution, gene-culture co-evolutionary methods are appropriate. For example, Feldman and Cavalli-Sforza [11] used gene-culture co-evolutionary theory to investigate the evolution of lactose absorption. By defining genotypes that differ in terms of their ability to process lactose, and by describing individuals as either having a meme for milk consumption or not, Feldman and Cavalli-Sforza were able to develop a population genetics model to explore how dairy farming and milk use might co-evolve with genes for lactose absorption. In this case, the cultural trait is treated as a discrete meme (milk user or nonuser), rather than as a continuous distribution, which simplifies the model without compromising the qualitative results. The analysis suggested that whether or not the allele for absorption achieves a high frequency depends critically on the probability that the children of milk users themselves adopt the meme. The analysis is able to account for both the spread of lactose absorption, and the culturally related variability in its incidence. Moreover,

Feldman & Cavalli-Sforza found a broad range of conditions under which the absorption allele does not spread despite a significant fitness advantage. Meme transmission complicates the selection process to the extent that the outcome may differ from that expected under purely genetic transmission.

In the lactose absorption example, the leash tugs both ways: whether or not an individual drinks milk depends on his or her genotype, but also whether or not the genes for lactose absorption are present in a population depends on the history of dairy farming in that culture. Such two-way influences are likely to have been common throughout recent human evolution, and may have been particularly important in the evolution of the human brain. A number of theories have related the change in brain size and associated anatomical effects with cultural change (Humphrey [14]; Holloway [13]; Wilson [20]; Byrne & Whiten [5]; Dunbar [8]; Aiello & Wheeler [1]). For example, the evolution of the brain with a costly, high mass specific, metabolic rate may have been paid for by a reduction in the size of the gastro-intestinal tract (Aiello & Wheeler [1]). Aiello and Wheeler [1] suggested that a reduction in gut size was only possible because the larger brains were capable of culturally mediated improvement in diet, in proportion to the loss of gut. Humphrey [15] emphasised the effect of social behaviour and hierarchy upon the evolution of brain size, resulting in the acceleration of cultural evolution. Wilson et al. [20] suggested the behavioural drive hypothesis, predicting that the dual capacity for behavioural innovation and social propagation of new habits accelerated anatomical evolution. Gene-culture co-evolutionary theory is suited to investigate the plausibility of such hypotheses.

One recent interesting addition to hypotheses concerned with brain evolution has been made by Blackmore [2]. Blackmore suggests that social learning and memetic drive are the cause behind the evolution of increased brain size, proposing a three stage process. Firstly, individuals with a predisposition for imitating (we will call them 'generalist' imitators, as they are not biased to learn from any particular individual) would succeed over those that only learn directly from the environment. Secondly, in a population of imitators, those with a predisposition to imitate from the best imitators would be selected (we will call them 'selective' imitators). Thirdly, preferential mating between enhanced imitators would produce the most successful offspring. The selective imitators are assumed to require a greater than average cognitive capacity, therefore there is selection for an increase in the average brain size. As this hypothesis comes directly from the memetics literature, in order to illustrate the gene-culture co-evolutionary method we show how one aspect of Blackmore's hypothesis can be tested using a phenogenotype model.

3 Imitate the Imitators

The first stage of Blackmore's model can already be regarded as to some extent supported by several gene-culture co-evolutionary models exploring the circumstances under which natural selection should favour reliance on social learning (Boyd & Richerson [3, 4]; Laland, Richerson & Boyd [16]; Feldman, Aoki & Kumm [9]). Here we concentrate on exploring the plausibility of stage two. We start with a population of 'generalist imitators', who show no bias to learn from any particular individual. We ask if a small number of individuals with a more selective capacity for imitation, in that they concentrate on imitating only other individuals with this selective tendency, would be at a selective advantage. If so, genes for imitating the imitators selectively would be expected to spread through the population. Blackmore assumes that the more selective

imitators will by definition be the best imitators, and will be more likely to adopt advantageous memes than generalist imitators. Here we show that this assumption is not necessary for selective imitation to spread, although it could easily be incorporated into the model and would almost certainly increase the likelihood that selective imitation would be favoured. Although we take issue with Blackmore's claim that imitation is the only process that can support meme transmission (Reader & Laland [19]), to accurately reflect Blackmore's position, here we restrict our use of the term imitation to the direct copying of a motor pattern. As the model considers the *consequences* of social learning, rather than the underlying psychological processes, it applies equally to any social learning processes, to the extent that they support meme transmission.

We assume that individuals adopt one of two memes (B_1 or B_0) with the assumption that meme B_1 is manifest as a novel behaviour that enhances the individual's fitness by γ_2 [note 1], relative to B_0 . B_1 may, for example, represent the ability to exploit a new, highly nutritious food source. We define as generalist imitators individuals of genotype ii , while selective imitators are of genotype II . The heterozygote, Ii , has intermediate imitative tendencies, depending on the level of dominance of I over i , given by the coefficient, β . As Blackmore suggests that individuals who can imitate the best imitators require a greater brain size, we attribute a fitness cost, γ_1 to the I allele, reflecting the extra neural investment, but nonetheless leave open the possibility that γ_1 may be set to zero. With three possible genotypes and two memes, there are six possible associations or phenogenotypes. Each phenogenotype has an associated fitness (see Table 1).

Genotype Meme	II	Ii	ii
B_1	$1 - \gamma_1 + \gamma_2$	$1 - \beta\gamma_1 + \gamma_2$	$1 + \gamma_2$
B_0	$1 - \gamma_1$	$1 - \beta\gamma_1$	1

Table 1: The fitnesses of the six phenogenotypes. Each fitness, reflecting the relative change in that phenogenotype frequency per generation with respect to selection pressures, is in the cell corresponding to the combination of the particular genotype (defined by column) and meme (defined by row).

Genotype	II	Ii	ii
Probability of B_1	$p1 = c \frac{F_{1I}}{(F_{1I} + F_{0I})}$	$p2 = c \left[\frac{\beta F_{1I}}{(F_{1I} + F_{0I})} + (1 - \beta)(F_{1I} + F_{0I}) \right]$	$p3 = c(F_{1I} + F_{1i})$

Table 2: The probability of acquiring the B_1 meme given genotype of the individual, where F_{pg} is the frequency of the phenogenotype in the parental generation. Note that the probability of acquiring the B_0 meme for an individual of a given genotype is just $1 - Pr(\text{acquiring the } B_1 \text{ meme})$.

After random mating with respect to the two memes and two genotypes, the B_I meme is passed down from the parental generation to the offspring generation in a manner dependent on its genotype (see Table 2).

The probability that an individual acquires the B_I phenotype depends upon its genotype, on the probability of social learning, c and the frequencies of B_I individuals of the parental generation. Whereas generalist imitators can potentially learn from all B_I individuals in the parental generation, selective imitators constrain themselves to copying the sub-population of selective imitators in the parental generation. In either case, the probability of adopting the B_I meme is directly proportional to its frequency in the relevant population.

Using the assumptions in tables 1 and 2, we can construct recursions defining the relationship between the frequencies of each phenogroup in the parental and offspring generations. In each offspring generation, phenogroup frequencies depend upon the probability of acquiring the genotype following random mating in the parental generation, the probability of acquiring the particular phenotype given the genotype (Table 2), and the fitness associated with the phenogroup in question (Table 1). In this case, the system can be reduced from six phenogroup recursions to a simpler system, with the following set of four recursions (1a-d). These recursions give the frequency of the I and i alleles in individuals with B_I and B_0 memes, respectively.

(1a)

$$WF'_{1I} = (F_{1I} + F_{0I}) \left[p_1 (F_{1I} + F_{0I}) (1 - \gamma_1 + \gamma_2) + p_2 (F_{1i} + F_{0i}) (1 - \beta\gamma_1 + \gamma_2) \right]$$

(1b)

$$WF'_{0I} = (F_{1i} + F_{0i}) \left[p_3 (F_{1i} + F_{0i}) (1 + \gamma_2) + p_2 (F_{1I} + F_{0I}) (1 - \beta\gamma_1 + \gamma_2) \right]$$

(1c)
$$WF'_{1i} = (F_{1I} + F_{0I}) \left[(1 - p_1) (F_{1I} + F_{0I}) (1 - \gamma_1) + (1 - p_2) (F_{1i} + F_{0i}) (1 - \beta\gamma_1) \right]$$

(1d)

$$WF'_{0i} = (F_{1i} + F_{0i}) \left[(1 - p_3) (F_{1i} + F_{0i}) + (1 - p_2) (F_{1I} + F_{0I}) (1 - \beta\gamma_1) \right]$$

where F'_{pg} is the frequency in the offspring generation, and W is the sum of all the right hand sides of equations 1a-d.

Analysing this mathematical system [note 2] reveals that whether selective imitators evolve in a population of generalist imitators depends on whether the following inequality is satisfied, namely

(2)
$$\left| c^{\frac{1}{2}} [1 - \beta\gamma_1(1 - \gamma_2) + \gamma_2]^{\frac{1}{2}} \right| > 1$$

Figure 1: The conditions under which a population of B_{0i} individuals is susceptible to invasion from the I allele under different magnitudes of fitness cost, γ_1 and levels of dominance (a-c), where γ_2 is the fitness advantage of meme B_I , and c is the probability of social learning.

Invasion occurs in populations with parameters to the right of the curved line.

The conditions under which a population of B_{0i} individuals is susceptible to invasion from the I allele under different magnitudes of fitness cost, γ_1 and levels of dominance (a-c), where γ_2 is the fitness advantage of meme B_I , and c is the probability of social learning. Invasion occurs in populations with parameters to the right of the curved line.

This result confirms Blackmore's intuition that there are conditions under which the selective imitation I allele can invade the population. These conditions are illustrated in Figure 1. It turns out that invasion is most likely when the fidelity of social learning, c and the fitness advantage of the B_I meme, γ_2 are high, whilst the dominance of I over i , β and the cost of selective imitation, γ_1 are low. The conditions for invasion rely most heavily upon the reliability of social learning, c , that is, the fidelity of meme transmission, with no chance of invasion if $c < 0.5$. However, it is possible that a high fidelity for meme transmission would already exist if we assume part 1 of Blackmore's hypothesis that effective imitation has already evolved in the population. The result shows clearly that if $\beta \gamma_1$ is high, there is less chance of invasion, as the inequality is less likely to be satisfied. If $\beta \gamma_1 = 1$ the left hand side of inequality 2 reduces to 0, making it impossible for allele I to invade. Interestingly, I is less likely to invade if it is dominant over i .

It is possible for selective imitators to evolve if either β or γ_1 is small, even if the other is large. That is, if there were little cost to selective imitation, it might evolve even if allele I is strongly dominant. Likewise, if allele i is strongly dominant, selective imitators could evolve even with a high cost. The effect of these scenarios is shown clearly in inequality 3. If we assume high

transmission fidelity of the memes ($c \approx 1$) and $\beta \gamma_1 \approx 0$, then the condition for the evolution of selective imitators merely requires a fitness advantage to B_I over B_0 ($\gamma_2 > 1$),

$$(3) \left| (1 + \gamma_2)^{\frac{1}{2}} \right| > 1$$

It is also worth stressing that if inequality 3 is not satisfied then selective imitators will not be favoured in a population of generalist imitators, and that there is an equivalent criterion by which generalists could invade a population of selective imitators. Were we to make the assumption that selective imitators are more likely to acquire B_1 than generalists (e.g. if c was not constant but had a higher value for selective over generalist imitators) then the probability of alleles for selective imitators invading and their stability to invasion would be enhanced.

We have developed this example to illustrate how a hypothesis can be neatly formalized and tested under the phenogenotype paradigm. In our judgement the analysis suggests that there are realistic circumstances under which Blackmore's hypothesis may be operational. However, given that advantages of imitating appear to be dependent on the pattern of spatial and temporal variation in the environment, a more sophisticated analysis incorporating a changing environment might be an appropriate next step. Having illustrated a method for addressing the general feasibility of Blackmore's hypothesis, it is now open for further analysis.

4 Conclusions

The cultural evolution and gene-culture co-evolutionary modelling paradigms can be effectively employed to enhance the quantitative study of memetics. Simple and complex cultural phenomena such as behaviour patterns, belief systems and institutions can be analysed by characteristics of associations between easily definable and quantifiable memes. The quantitative approach can be used to describe meme diffusion dynamics, and make sense of patterns of variation in memes. The methods can also ask why and how human attributes evolved in conjunction with memes, how they continue to evolve, and what is the basis of any stability or maintenance of the trait.

Notes

1. If your browser has written 'g' instead of the Greek letter gamma, then you should note that $g_2 = \gamma_2$; $g_1 = \gamma_1$; and $b = \beta$.

2. We consider the evolution of selective imitators, by assessing the local stability of the initial population consisting solely of B_{0i} individuals. Inequality (2) shows the conditions under which the B_{0i} population would be unstable, and susceptible to invasion from the I allele, and is

calculated by finding the Eigenvalues of the Jacobian matrix at $\hat{F}_{0i} = 1$. Invasion is restricted to parameter values that give the leading Eigenvalue a magnitude greater than unity, indicating that B_{0i} is not asymptotically stable with a small perturbation from equilibrium.

DIFFERENT TYPES OF MEMES: RECIPEMES, SELECTEMES, AND EXPLANEMES

By

John Z. Langrish

Manchester Metropolitan University

JLangrish@aol.com

Abstract

This paper attempts to provide three directions for advancing Dawkins' original description of memes as 'units' of cultural transmission'. These three directions are

1. There could be different types of memes.
2. Memes are not 'units'.
3. The transmission of memes might not be restricted to something called 'culture'.

A biological perspective allows for different types of memes with different transmission mechanisms. The disease type mechanism (epidemiology) has been over emphasised and is only one such mechanism. Three types of memes are suggested and given the names recipemes, selectemes and explanemes. Their use is illustrated by the evolution of technology in which black box systems are used to do things requiring recipemes - ideas about how to do it - and selectemes - ideas about what is a desirable output. Explanemes are ideas about the inside of the 'box'.

Key words: memes, evolution, culture, technology, biology.

1 A Biological View

The three lines of advance, mentioned above, stem from a 'biological' view of the world as opposed to a 'physics' view. This 'biological' view (abbreviated to **B**) is based on Darwinian evolution but has roots going back to Aristotle's tendency to develop typologies i.e. accounts of different types of things. The 'physics' view (abbreviated to **P**) is based on Newtonian mechanics but has roots going back to Plato's concentration on the essence of things rather than their differences. The big difference between the **B** and **P** views is that **B** welcomes diversity and **P** hopes for one theory of everything. ('Real' Physics and Biology are not quite the same as **P** and **B**. Fundamental particles begin to look like botany and reductionist biologists seem to think like physicists)

Scientific thinking is so imbued with the **P** view that it sometimes seems that the existence of an alternative scientific way of looking at things has been kept a carefully guarded secret. One of the few people to attempt an account of **B** is Ernst Mayr whose 'The Growth of Biological Thought' (Mayr 1982) is recommended to economists, sociologists and anyone interested in evolution.

Certain features of the **B** view need highlighting to provide a background for the **B** view of memes. These are:-

i) There is no such thing as a single cause for any event or process in biology. For example Steven Rose (1997 p 10) gives five different explanations for a frog jumping away from a snake. These range from its evolutionary history to the biochemical properties of its muscles. The processes by which ideas are transmitted are surely more complex than the reaction of a frog to a snake.

ii) **B** concepts are fuzzy patterns and advances are made through subdivision. (This is the opposite of **P** which has mathematically precise concepts and likes to reduce the number of concepts, not increase them).

As Mayr (1982) puts it-

"Particularly important (in scientific progress) is the occasional recognition that a more or less technical term, previously believed to characterise or designate a certain concept, was in reality used for a mixture of two or more concepts, like 'isolation' for geographical and reproductive isolation or 'variety' for individuals and populations." p43

It seems reasonable to suggest that advances in memetics could also be made by regarding concepts as mixtures or patterns rather than by attempting precise definitions.

iii) The need for descriptive studies. Biology used to be sneered at as one of the descriptive sciences. Its higher status today has partly come from adopting a **P** approach, sometimes referred to as reductionist molecular biology.

Yet Mayr (1982) claims,

"In evolutionary biology almost all phenomena and processes are explained through inferences based on comparative studies. These in turn are made possible by very careful and detailed descriptive studies. It is sometimes overlooked how essential a component in the methodology of evolutionary biology the underlying descriptive work is." p.70

What is needed to advance memetics is detailed studies of memes competing and surviving. The history of ideas is a start. This can become the evolution of memes but more is needed; the day to day natural history of memes needs to be added to existing notions of influential ideas, their propagation and recombination (e.g. Lovejoy 1936). Darwin's theories came after years of detailed study, not before.

iv) The nature of evolution. From the **P** view, evolution is 'unfolding' but biological evolution is NOT a gradual unfolding of a predetermined pattern. The growth of an embryo or the growth of an oak tree from an acorn are examples of 'unfolding' or development.

Confusing unfolding which is predictable with Darwinian change which is not, is a mistake made mainly by physicists who tend to believe that everything in principle is predictable. Thus a report

in the *Times Higher Educational Supplement* (12 April 1996 p3) describes the computer modelling of the growth of the Universe. The article refers to 'the latest step in unravelling the evolution of the universe'. It quotes Carlos Frenk, Physics Professor at Durham University, as saying, "*Imagine you could do a computer simulation that would take the fossil record and evolve it until we see the human growing*". The article also refers to the 100,000 years old universe as, "*the embryo universe*".

The development of an embryo is actually quite a different process from the changes that led from the life represented by the fossil record to our present existence. It is only with the advantage of hindsight that we might reconstruct the evolution of humanity. If some scientific being came from outer space and only had fossils up to the time of say the reptiles, there is no way that humanity could be predicted from these fossils. At any stage in biological evolution, the number of possible future states is enormous. Those varieties that do survive and lead to further varieties do so partly by luck and coincidence and because of environmental changes which are also not predictable.

This is why some physicists claim that the Darwinian theory of evolution is not a scientific theory at all (the only science is physics; the rest is stamp collecting or social work or cookery or qualitative description, depending on which quote you prefer). Nonetheless, the **B** view is a scientific view. It can make predictions that can be tested - predictions about the fossil record for example. Any good classification system (stamp collecting) provides predictions. If a new chemical is identified as being secondary, it is possible to predict some of its properties and ways of making it from other chemicals. Mendeleev's periodic table, a two dimensional classification system or pattern, predicted the existence of two unknown elements which were soon discovered. This prediction was possible without any knowledge of electrons, the nature of the chemical bond, wave mechanics etc. which are the product of **P** type approaches. What Darwinian evolution cannot do is predict the future results of change; it is not an unfolding development.

v) The importance of variety (of whatever kind). This can be summarised as: Without variety there is no competition. Without competition there is no evolution. Without evolution there is no biology. In contrast, the **P** view likes things to be the same. Where variety does exist, this is reduced to 'deviation' from the 'norm'. The emotive connotations of these two words demonstrate the preferences of **P** type thinkers. Mayr's version of what I label **P** and **B** is his essentialist vs. populationist divide. He claims (Mayr 1982),

"The statistics of the essentialist are quite different from those of the populationist...Differences in height among a group of people are real and not the result of inaccuracies in measurement. Darwin could not have arrived at a theory of natural selection if he had not adopted populational thinking. The sweeping statements in the racist literature, on the other hand, are almost invariably based on essentialistic thinking." p.47

In other words, variety is to be embraced and not regarded as something that gets in the way of prediction. Different kinds of memes having different methods of propagating and altering have to be the starting pattern for advances in memetics. (**B** advances from a pattern; only **P** has a

starting point). Armed with a **B** view of the world, we can take a fresh look at Dawkins original statement on memes.

2 Three Lines of Advance

As readers of the Journal of Memetics will know, Dawkins (1976 - Chap 11) described memes as units of cultural transmission. The word is a contraction of mimeme. Examples of memes given by Dawkins are *"tunes, ideas, catch phrases, clothes fashions, ways of making pots or of building arches"*. Richard Dawkins is described by Niles Eldredge (1995) as the ultimate ultra-Darwinian and Eldredge claims, *"Ultra-Darwinians are guilty of a form of 'physics envy'"*. The failure of Dawkins and others to develop the meme of memes may be due to **P** type thinking, especially concentrating on 'units'. In calling memes 'units of cultural transmission', Dawkins could have been mistaken about three things, representing three lines of advance; these are:-

2.1 Memes are not all the same

There are different types of memes. Memes are biological entities - not physics type particles. Progress can be made by identifying different kinds of memes with different ways of competing and different ways of being transmitted and changed.

2.2 Memes are not units; they are patterns - or Russian dolls

P type units are essentially the same as each other. An atom of sodium may be a different isotope or in a different energy state but an atom of sodium is the same now as it was a million years ago or as it would be a million miles away. (Once you have seen one you have seen them all). **B** type things are different - they vary and change over time and place. An elephant in India is different from an elephant in Africa and in fact every elephant is unique. The 'idea' of a meme is not a unit; it is a complex concept meaning different things to different people. Some see memes as being infectious parasites invading the mind i.e. different from 'ordinary' ideas. Others do not draw this distinction.

The 'idea' of a railway is not a 'unit'. When the Liverpool - Manchester railway was built, many people could 'catch' the idea of a railway from looking at it working. This did not mean that they could then go and build railways somewhere else. The amount of information needed to construct and run a railway system is enormous. The meme of a railway is a Russian Doll, which includes knowledge of suspension systems, traction systems, signalling, time tables, track maintenance, safety, finance, customer preferences etc. No single human has the complete 'idea' of a railway in a brain or a computer. From the point of view of an observer rather than an operator, the idea of a railway might be thought of as a pattern consisting of fragments of memory assembled around a label - railway. From the point of view of a user, a railway is an idea in competition with ideas about other forms of transport. Whatever is meant by the idea of a railway, it is different for different people and it is not a unit.

Some writers (e.g. Ball 1984 and Durham 1991) have seen memes as being more than unit bits of information or unit ideas. They can be complexes of things, behaviour and ideas but still transmitted as units and firmly placed in something called culture. Now it is possible to define

culture in such a way as to include almost everything 'out there' but such definitions usually include something about cultural transmission. This brings us to the next point.

2.3 Memes are not restricted to cultural transmission; other forms of transmission are possible

Some writers with an interest in cultural evolution anticipated Dawkins 'memes'. There is a tradition which sees culture as something having an evolutionary life of its own. (Spencer's social evolution which preceded Darwin by three years, described culture as super organic, coming on top of the organic - living - and the inorganic - inanimate). Thinking along these lines produced antecedents to Dawkins' memes. If there is an independently evolving culture, it might have something analogous to genes or it might actually have its own form of genes. Suggested names for these genes of culture include mnemotype (Blum 1963), culturetype (Burhoe 1967), sociogene (Swanson 1973) and culturgen (Lumsden and Wilson 1981). These writers share with Dawkins a tendency to view the world from a **P** perspective which causes problems because evolution needs a **B** view.

A **P** view of things is pleased by identical fundamental particles - hence units. Such a view also likes fields in which to place its basic units. Culture to Dawkins and others seems to provide the field in which the meme particles move about. Culture, however is not **P**; it is **B**. It is not like a gravitational field in which projectiles have predictable trajectories (until humans intervene). It is a biological field in which things grow and compete. A problem with culture is knowing which way round to look at the relationship between culture and humanity. Is culture something created by humans or are humans at the mercy of whatever culture they happen to be born into? Is it an agricultural field, artificially selected or is it a wild field, naturally selected? (Or from a chemical perspective, is there a 'bond' between humans and culture? - Bonds go both ways). From the many definitions of culture, the following might help to show why I think this term does not help memetics -

"culture is viewed as man's way of maintaining life and perpetuating his species, a system of learned and socially transmitted ideas, sentiments, social arrangements and objects that depend for their formulation and continuation upon man's ability to create symbols." (Gamst and Norbeck 1976).

Quite apart from the outdated emphasis on 'man' having all the fun, I am in disagreement with two aspects of this definition, the inclusion of objects - not ideas about objects but the actual objects - with everything else and the necessity of having symbols for transmission. Now certain kinds of ideas do require symbols. The ideas of science, for example, and explanations in general need words or maths for their transmission. (It might be that having explanations is the one real difference between the human and other animals). This kind of transmission is not always necessary for other types of ideas such as ideas about how to do things. Ideas about playing the piano or making even apparently simple things, like pots, are very difficult to put into words or other symbols. They involve 'finger tip' knowledge and ideas about things feeling right. An idea of how to do something can be transferred more easily by doing it than by describing it. Written music, of course, involves symbols but written notes do not tell you how to play the piano. Tunes

can be transmitted by written music but more often their transmission has no dependence on symbols. Cymbals can be better than symbols for the transmission of musical ideas.

Another description of culture is provided by Lumsden and Wilson (1983), who state,

"Human cultures consist of artifacts, such as knives of a certain shape and function; behaviours, such as initiation rites of a particular form; and mental constructions having little or no direct correspondence to reality such as myths."

To lump together knives, initiation rites and myths under the label 'culture' may be all right for those who want to see the world that way. I don't. I have a suspicion that the knives are more important and that transmission of ideas about knives is different from the transmission of mythical ideas. Though I am sure that myths need words or other symbols for their transmission, I am also sure that knives don't. A knife is its own picture- a representation not a symbol. Using a knife can be copied directly.

To make any progress, we have to unpack this 'culture includes everything' approach to look at different kinds of memes with the possibility of different means of transmission. To those who cannot imagine a meme without cultural transmission, I would say, what is the meme of a railway? Does it require a railway culture in order to move from one country to another and if not, why not?

Before attempting to describe different types of memes, it is necessary to discuss another aspect of transmission that has held up memetics, namely a fascination with memes as parasites or viruses.

3 Epidemiology - a side track

Much of what has been written about memes can be summed up by the title of Aaron Lynch's book (1996), 'Thought Contagion'. This approach has been used to attack both Communism and religion, provoking a counter attack by John Bowker whose 'Is God a Virus?' (1995) attempts to bring free will into the discussion.

If some extra-galactic intelligence discovered our earth, they might be expected to be interested in carbon based life. However, if after twenty years they had only studied viruses and parasites we might think they were deficient in curiosity or just weird. Why no interest in ants, elephants, spiders, trees, eagles, coral, sharks or fungi? It is a bit like that with memes; why such little interest in the memes of technology, poetry, design, economics and all those interesting human activities involving ideas. After all, Dawkins' original description of a meme included 'ways of making pots and building arches'.

There are two further problems with the memes as viruses school of thought. One is that it ignores Dawkins original use for memes - as the basis for a new kind of evolution, acting on top of genetic evolution. Epidemiology is not in itself evolutionary unless it asks historical questions about the viruses. The second problem is that it has not found a use for memes as such. Ideas about the spread of 'foreign' ideas have been around a long time. Have they been improved by

the addition of memes? Older readers will remember Vance Packard's *Hidden Persuaders* (1957) and might have come across William Sargant's *'Battle for the Mind'* (1957) which has the opening remark,

"...this book is not concerned with the truth or falsity of any particular religious or political belief. Its purpose is to examine some of the mechanisms involved in the fixing or destroying of such beliefs in the human brain." p.9

Memetics has added some new words to describe the transmission and effects of memes, e.g. Glenn Grant (1990) has bait, dormant, hook, membot, meme allergy, sociotype, vaccime and so on, which are fun but don't really add very much to a discussion of ideas outside religion and politics. This emphasis on religion and politics and the disease-like nature of the spread of 'foreign' ideas would not have mattered too much if this tendency had been confined to those Xenophobic Americans wanting to believe that Communism was a dangerous infection capable of sapping the minds of true Americans (e.g. Peter Vajk, 1989) claiming that perestroika was a deliberate strategic deception by the infectious meme of Communism). Unfortunately, the meme of the infectious meme seems itself to be rather infectious. The author of the immortal quote, *"Memes share the farmyard with us and it is up to us which of them we let push us around"* (Westoby 1994) was not a hawkish American - he was an English Lecturer in Education, with so called left wing views.

Dawkins himself seems to have added little to memes beyond his diatribe against religion (Dawkins 1993) apparently fuelled by his six year old daughter being given instruction by a nun without his knowledge. The big problem with memes as viruses, parasites or even symbiotes is how do you know which memes are 'you' and which are 'invaders'. Dawkins (1993) glimpses this problem with an afterthought about science. Couldn't the ideas of science be just the same as the ideas of religion; that is 'caught' from teachers, books etc.

'No', says Dawkins (1993):-

"The rapid spread of a good idea through the scientific community may look like a description of a measles epidemic. But when you examine the underlying reasons you find that they are good ones, satisfying the demanding standards of scientific method. For scientific belief, epidemiology merely comes along afterwards and describes the history of its acceptance. For religious belief, epidemiology is the root cause." p.23

To me this really does not help. How do you know that a reason is a good one? You have to have ideas about what is a good idea - selectemes. Such ideas can be 'caught' as easily as any other kind of idea. As Dennett puts it (1995):-

"it cannot be 'memes versus us' because earlier infestations of memes have already played a major role in determining who or what we are. The independent mind struggling to protect itself from alien and dangerous memes is a myth." p.365

Dennett removes the polarity between us and the invaders by seeing our notion of self as the result of 'infestation'. The idea that the mind begins its life as a clean slate or an empty vessel

waiting to be filled goes back a long time (e.g. John Locke (1690) wrote about the mind being at first a 'yet empty cabinet' which was furnished by experience.) This notion leads to thinking about the source of the ideas that are supposed to fill the empty mind and some people have seen a quasi independent culture as the filling agent. It can be seen that the two uses for memes - memes as nasty invaders of an independent self and memes as the units of culture without which there would not be a 'self' - are as different as sociology and psychology or as macro and micro economics. They ought to meet but they don't. My aim is to find something different from either of these limited perspectives.

I want to know the difference between a belief that is somehow based on evidence and one that is not. I want to know how ideas change with time - how they evolve. To answer these kinds of questions, I need a biological evolutionary approach using different kinds of memes involving different transmission methods.

4 Different kinds of memes

4.1 Memes for evolution

My own interest in memes lies in the possibility of using them in an evolutionary framework for discussing technological innovation. An evolutionary viewpoint requires:

- Variety
- Competition between the varieties
- Replication of the 'winners'
- A mechanism for the production of further variety (followed by further competition)

A mechanism for changing the 'rules' of the competition. (Without this requirement, evolution stops when diminishing returns from further variety lead to equilibrium)

From a modern viewpoint, the evolution of technology is the evolution of ideas about artifacts within environments which select certain ideas and reject others. Competing ideas are first subject to selection within a mind- they compete for attention. They then compete for approval by people who control resources. A very small proportion of ideas end up incorporated in something else, an actual artifact, a process, a system etc. These things then seem to compete with each other in an exosomatic (outside the body) evolutionary process.

Jean and Peter Medawar's book(1978) has a chapter on exosomatic evolution which starts,

"Everybody has observed that the human artifacts which serve as tools are to some extent extensions of the body".

They are probably rather optimistic about the observational power of 'everybody' but that is just a way of saying that they cannot remember how they got such an idea. Way back in 1872 Samuel Butler expressed this idea in 'Erewhon' (almost 'nowhere' spelt backwards but pronounced with three syllables) pointing to a spade as an external limb, a note book as an external memory, a magnifying glass as an external eye etc. The Medawars then add on to Butler's concept of

evolutionary external organs the point that it is not the tools (organs) that evolve but ideas about tools:

"It is very clear that these exosomatic parts of ourselves undergo a slow systematic secular change of a kind which it is perfectly possible to describe as involution' - exosomatic evolution - provided of course one realises that it is the design of these instruments that undergoes the evolutionary change and not the instruments themselves, except in a quite unnecessarily figurative sense".

Instead of drawing a parallel between genes and designs (both are `instructions' that affect the production of something), the Medawars add on ideas from cultural evolution. They say:

"Ordinary organic evolution is mediated through a genetic mechanism but exosomatic evolution is made possible by the transfer of information from one generation to the next through non-genetic channels. By far the most important of these non-genetic agencies is language. It is because of the primacy of language... that exosomatic evolution is often referred to as cultural or psychosocial evolution". chap.6

So culture and language are still in the picture. Ideas about technology, however, can be transmitted without words and without invoking some cultural `field'.

Competition between ideas leading to some ideas being replicated, modified or added to can be discussed without reference to `culture' (which is not the same as saying ideas are culture free - just that some ideas, like some microbes can be transmitted between cultures even though both ideas and microbes can flourish within an appropriate `culture')

Technology moves across cultures quite easily. If your tribe is attacked by a new tribe armed with bows and arrows which kill humans and animals then your tribe absorbs the idea of bows and arrows. You don't have to learn the language of the new tribe to do this nor do you need the special prayers and ceremonies which the new tribe associate with making the bows and arrows; you have to watch them being used and perhaps capture some. Bows and arrows can be imitated. This is not the same as saying all artifacts can be easily imitated; nor is it the same as saying artifacts are culture-free. It is just saying that the meme of using bows and arrows is better described as a technological pattern, a Russian doll idea of how to do something rather than a unit of cultural transmission. Since I think about technology as a way of doing something better than it could be done by an unaided human, a convenient class of memes is ideas about ways of doing something. I propose to call these recipemes.

4.2 Recipemes, selectemes and black boxes

Recipemes are competing ideas of how to do things. Successful recipemes are replicated - sometimes with modification or addition. Recipemes have a different method of transmission from the other memes. Knowing how to do something often involves `finger tip' knowledge which can only be obtained through doing. You cannot tell someone how to ride a bicycle, when the clay for a pot feels right, how to play the piano or how to knap a flint. You can write down the recipe for a cake but this will assume some shared practical knowledge.

Once we have different ways of doing different kinds of things, we have ideas of success and betterness. Some things and some ways are 'better' than alternatives. I propose to use the word, 'selecteme' to mean ideas that form the basis of selection. Selectemes are competing ideas of betterness. They provide the mental environment in which other memes compete for selection. (Selectemes, of course, compete with other selectemes!) The transmission of selectemes is closely bound to something that might be called a society - in an early version, I tried calling them societemes but decided that was too restrictive.

Many people, of course, don't accept all the selectemes that are offered them. Some have Friday night selectemes that are different from those that are present on Monday morning. So how do we select our selectemes? P-type thinkers will immediately see an infinite regression of minor selectemes being selected by higher order selectemes which are... . However, in a B world, things form non mathematical patterns. A selecteme is a Russian doll type pattern which forms a whole. When we feel that something is wrong, we do not think, "I will not do that because it would be stealing and stealing is against my religion which I have chosen to abide by even though I do not believe in God and in any case I might get found out and that would bring shame which I do not like..." No, we either just feel it would be wrong or we feel it is worth the risk. Either way that feeling can be described as a pattern of selection which the pattern of proposed action either fits, does not fit, or is repelled by. When a pattern of action fits a pattern of selection, we have a 'click' which Maria Abu-Risha (1999) calls *Purposive Pattern Recognition*. An important point is that patterns are not units nor are they always made of the same units. The pattern of the letter A can be constructed out of many things including a hole.

Recipemes and selectemes can be combined in black box systems. A black box can be a rubber tree, a chemical reaction, a loom, a bow and arrow or anything that has inputs and outputs under some degree of control. Recipemes are ideas about inputs into boxes (raw materials, energy and conditions) and about alternative boxes. Selectemes are ideas about outputs and their relative desirability. Since boxes can be connected - the output from one being the input to another - there can be long chains of recipemes and selectemes. The loom maker makes a loom using selected materials made elsewhere; the weaver selects a loom to make cloth from selected yarns made elsewhere; the tailor turns the cloth into clothes and the clothes are purchased and worn. At each stage there are recipemes - ideas about how to do things - and selectemes - ideas about what sort of loom, yarn, cloth and clothes might be desirable or undesirable.

In addition to forming long chains of inputs and outputs, recipemes and selectemes can form Russian doll nesting structures. The human body is a special black box. Part of its input is food. If someone decides to bake a cake, selectemes for healthy life style and sensuous enjoyment compete, leading perhaps to a creamy, fatty chocolate cake or a fat-free cake made from organic whole meal flour. Inside these selectemes and recipemes will be other more specific ones. Which recipe for a healthy cake or a delicious cake might be used? Someone might have a selecteme for Delia Smith; someone else for mother's trusted recipe. The person making the choice does not work through a decision tree. They do not think, "I am in favour of being healthy so I must have a healthy diet and that means using a recipe from 'Recipes for a Healthy Life' in which is a rather nice cake which I have made before and my friends enjoyed". No, they just think, "I'll make that cake again". The actual cake when made and eaten by other people might influence future

choices made by others. Recipes do get copied and ideas of what is a 'good' cake can be changed. Such changes usually involve real cakes rather than symbols of cakes. So we now have a view of the world consisting of interacting black boxes. Humans attempt to alter this world through thinking and doing. Black boxes can be observed and their inputs can be altered. Different inputs give different outputs some of which are judged to be desirable or more desirable than existing outputs. Different black boxes can be tried out. Ideas about inputs and boxes are recipemes. Ideas about desirability of outputs are selectemes. These ideas compete firstly in one mind and then in the world and then in the minds of other people.

4.3 Explanemes and Institutions

A third type of meme is required to describe ideas about what is happening inside the black box. I propose to call such ideas explanemes. Explanemes are competing ideas that are used in answering questions about why things work or work better. Selectemes associated with both curiosity and communication enable the survival of ideas about the insides of the black boxes. These 'inside' ideas are explanemes.

Some explanemes lead to suggestions for new black boxes or improvements in existing boxes. Some are 'just - so' stories. Some provide words to enhance communication. Some are highly sophisticated and live in special institutions. Explanemes are competing ideas that are used in answering questions about why things work, work better or don't work. Recipemes just tell you how to make something. Explanemes provide a story about what is going on. The transmission of explanemes always requires a language - maybe maths - maybe symbols - but you can not tell a story about something without a story telling language. Stories do translate from one culture to another and so do special symbols such as algebra which moved from an Arabic origin to a European usage.

Explanemes may be expressed in a specialist vocabulary to assist communication about black boxes, their recipemes and appropriate selectemes and they may fit into an environment of curiosity. Competition between explanemes takes place within the mind of anyone who is wondering 'why?'. Competition also takes place within complex organisational structures of the kind that are usually called institutions. Scientific institutions provide an environment for the competition between scientific explanemes. This way of looking at science has been neatly described by John Ziman (1998) as,

"a peculiar type of social institution, devoted to the production of public, communally acceptable knowledge about the natural and social worlds through a delicately balanced tension between originality and criticism".

Ziman's description of science meets the requirements of an evolutionary system (though that is not his intention). Originality is a variety production system. Criticism is the arena of competition. The 'winners' are reproduced through becoming communally acceptable. His delicately balanced tension is also descriptive of biological evolution in that the rate of mutation of genes is not so high as would lead to the loss of successful characters nor so low as would lead to a lack of adaptability.

An explicitly evolutionary approach to science has been provided by David Hull (1988) who claims that the pressures that shape the rise and fall of species are similar to those acting on scientific ideas. He makes use of a selection system involving replicators and interactors. His conceptual replicators could be seen as memes but there is a potential clash here with those such as Susan Blackmore (1999) who see memes as units of imitation. Scientific ideas are passed on but not by imitation. The potential clash is avoided if we have different types of memes with different methods of transmission. Explanemes differ from other memes in that they are not transmitted by imitation. They are still memes, however and they form part of an evolutionary system which sometimes involves institutions.

It is not just the explanemes of science that compete within institutional frameworks. Other types of memes also have special institutions with 'a delicately balanced tension between originality and criticism'. Thus manufacturing industry provides an arena for competition between different technological recipemes. The institutions of regulation, law and government oversee competition between those selectemes that are written down and enforced.

5 Memes and Evolution

We now have to add the dimension of time. Given different types of memes and institutions producing a delicately balanced tension between originality and criticism, we have a mechanism for evolutionary change which could transform economics, politics, sociology etc. In particular, technological evolution becomes a much more interesting concept than has been the case. Many people have considered the evolution of technology as hardware. For example Basalla (1988) has a four component evolutionary system which is worth looking at. These four concepts are diversity, continuity, novelty and selection (applied to things rather than to ideas). An essential part of Basalla's case is the continuity of all technology right back to the use of the first stones and flints. Basalla's continuity is of the strong variety. He is not talking about use or concepts. He claims, "Any new thing that appears in the made world is based on some object already in existence". In support of this he tackles some tricky cases. The electric motor, for example, is based on two existing devices- the magnetic compass and the steam engine.

Basalla also discusses the transistor and shows that the first commercial transistors were regarded as improvements on the old style crystals which had preceded the thermionic valve. Literature from Bell in 1948 announced, "*In the Transistor, two point contacts of the 'cat's whisker' or detector type, familiar to radio amateurs, are made to the semiconductor*". The point contact transistor was soon replaced by the junction type but it provided an evolutionary link. In Basalla's four component system, the concept of continuity is the weak link.

Just what does it mean to say that something is based on something else? This is why we need memes. If we take the Medawars' point that it is ideas that evolve then we are looking for a system which allows ideas to compete, propagate and change.

The first question has to be, why do we need memes to have an evolutionary theory of technology? Why not just stick with ideas and their history? You can have a history of ideas without using memes. It has been claimed that Arthur Lovejoy invented the history of ideas as an academic discipline (he certainly founded a Journal) but the introduction to his 'Great Chain of

Being' (1936) clearly states that he was looking for atomistic 'units'. Since advances may lie in the direction of scrapping the notion of idea units, Lovejoy's approach will not help.

Ideas change over time; they evolve. Selectemes (ideas about what is best) evolve and other memes have to adapt to their changing environment. Thus the planners of the Concorde shared the selecteme that faster meant better. So the world's first supersonic civil air travel became possible. However, the selecteme for fast lost out to other selectemes to do with both economy and noise. Different selectemes compete for the mental space marked 'the idea of the best' and different recipemes compete to supply ways of achieving the desired result. Some ideas are more competitive in association with a reason; so we find that explanemes are required to assist.

To summarise, memes are needed for evolutionary explanations of human activities. They compete, replicate and vary. They are involved in much more fascinating activities than those suggested by epidemiology. The concept of memes becomes more sophisticated and powerful when broken down into different types of memes with different ways of competing and being replicated. Lack of space prevents discussion of where new ideas come from but it should be obvious that the different memes whilst sharing the common features of an evolutionary system have different variety production mechanisms. New explanemes sometimes result in a Nobel Prize. New recipemes can be patented in the name of their inventor. New selectemes are rarely associated with a named individual (there are some notable exceptions such as Schumacher's Small is Beautiful) but many new ideas seem to crop up simultaneously. There is a need for studies of meme mutation; we don't need any more epidemiology. Evolution and memes need a 'B' view of the world. The spreading of identical units through a cultural 'field' is far too 'P' to be much help in the complex adaptive world of humans, their artifacts and their changing ideas.

A NOTE ON THE ORIGIN OF “MEMES/MNEMES”

By
John Laurent
School of Science
Griffith University

In the *Selfish Gene* Richard Dawkins says that he had originated the term 'meme', a cultural equivalent of 'gene', by shortening 'mimeme' which he says he derived from the Greek mimeisthai, to imitate. This may be, but another, and more straightforward source for the term, I would suggest, is 'mneme', referring to a unit of memory and taken from the Greek mimneskesthai, to remember (and ultimately from Mnemosyne, the Greek goddess of memory [Note 1]), and which appears in the book *The Soul of the White Ant*, by the Belgian dramatist, essayist and amateur entomologist, Maurice Maeterlinck, first published in 1927. Nowhere does Dawkins refer to 'mneme', but it is difficult to believe that he had not come across the term, especially since he has much about termites in both *The Selfish Gene* and *The Blind Watchmaker* and cites a number of works about these creatures (though not Maeterlinck's) in both books. Also, in an endnote in the second (1989) edition of *The Selfish Gene*, where he elaborates on a sentence in the main text of the book which reads "*Memes should be regarded as living structures, not just metaphorically but technically*".

Dawkins writes as follows:

"DNA is a self-replicating piece of hardware. Each piece has a particular structure, which is different from rival pieces of DNA. If memes in brains are analogous to genes they must be self-replicating brain structures, actual patterns of neuronal wiring-up that reconstitute themselves in one brain after another. I had always felt uneasy spelling this out aloud, because we know far less about brains than about genes, and are therefore necessarily vague about what such a brain structure might actually be. So I was relieved to receive recently a very interesting paper by Juan Delius of the University of Konstanz in Germany, [who] is bold enough to ram home the point by actually publishing a detailed picture of what the neuronal hardware of a meme might look like" (Dawkins, 1989, p.323).

Now, the actual phrase that Maeterlinck uses - where he is discussing various theories which attempt to explain 'memory' in termites as well as the other 'social' insects (ants, bees etc.) - is "*engrammata upon the individual mneme*" (Maeterlinck, 1927, p.198), and according to my dictionary (Webster's Collegiate), an engram is "*a memory trace; specif.: a protoplasmic change in neural tissue hypothesized to account for persistence of memory.*" For what it is worth, Maeterlinck explains that he obtained his phrase from the "*German philosopher*" Richard Semon. The only book that I have been able to locate by this author (who describes himself as a naturalist, though he could have said 'natural philosopher' in the parlance of the time) is *In the Australian Bush and on the Coast of the Coral Sea* (Semon, 1899), but this book is nevertheless interesting in the present context in that Semon does indeed devote some pages to a discussion of animal intelligence and 'instinct' in it, together with possible correlations with brain structure (in Echidna, for example, whose brain "*in proportion to the size of the body...is more voluminous*

than that of marsupials, and is further remarkable for its degree of convolution and the fissures on its surface".

To repeat, it is hard to believe that Dawkins was not at least aware of Maeterlinck (who also wrote *The Life of the Bee*, which my copy shows went into 34 printings [in English] between 1901 and 1948), and this author's use of the term 'mneme'. In any event, Semon's earlier specific use of the term in an identical context to that in which Dawkin's correspondent Delius - another German writer - uses 'meme' is a remarkable coincidence.

Notes

THE REDEFINITION OF MEMES: ASCRIBING MEANING TO AN EMPTY CLICHE

By

Michael R. Lissack

Naples, FL

lissack@lissack.com

Abstract

By redefining memes as efficient tools for evoking particular affordances to be attended to in situ, this article argues that the challenges Edmonds (2002) issued to memetics can be met. Such a definition is consistent with theories of niche construction. The indexical Dawkins created (meme=gene) has exceeded its carrying capacity and thus lost its efficacy. Worse, that indexical is evoking images and affordances which stand in the way of the memetics field making true progress. It is time to recognize that ontic status has been misplaced. Memes needs a new meme: meme as catalytic indexical.

1. Introduction

Memetics has reached a crunch point. If, in the near future, it does not demonstrate that it can be more than merely a conceptual framework, it will be selected out. While it is true that many successful paradigms started out as such a framework and later moved on to become pivotal theories, it also true that many more have simply faded away. A framework for thinking about phenomena can be useful if it delivers new insights but, ultimately, if there are no usable results academics will look elsewhere. Such frameworks have considerable power over those that hold them for these people will see the world through these "theoretical spectacles" (*Kuhn, 1969*) — to the converted the framework appears necessary. The converted are ambitious to demonstrate the universality of their way of seeing things; more mundane but demonstrable examples seem to them as simply obvious. However such frameworks will not continue to persuade new academics if it does not provide them with any substantial explanatory or predictive "leverage." Memetics is no exception to this pattern. (Edmonds, 2002)

While the popular media has had several rounds of fascination with the concept of memes, the application of memes to management and to complexity has been negligible. The Edmonds quote above ascribes the problem to the stage of development of memetics: that memetics needs to provide explanatory leverage to get past the "crunch point."

This article suggests that the answer to memetics' "crunch point" lies in turning the concept of memes inside out. If memes are "units of cultural transmission which propagate themselves" (Dawkins, 1976) or "the least unit of sociocultural information relative to a selection process that has favorable or unfavorable selection bias that exceeds its endogenous tendency to change" (Wilkins, 1998), then the failure of the field of memetics to meet the three challenges outlined by Edmonds (a conclusive case study; a theory for when memetic models are appropriate; and a simulation of the emergence of a memetic process) is problematic and perhaps indicative of

"irrelevance." Indeed, there have been few managerial examples of the potency of a meme to explain or cause anything — and in the absence of explanatory or casual power; it is difficult to find the relevance of a concept for managers.

If, on the other hand, memes are redefined such that the evolutionary selection process is no longer an aspect of the ontology of memes but rather of the environmental niche (cf. Laland & Odling-Smee, 2000; Laland et al., 1999; Odling-Smee et al., 2003) of which the memes are evidence, then the field may have other avenues of advancement and a potential relevance to managers. Such a redefinition would entail recognition of the relationship between a given meme and the context of the social and ideational environment of which it is an affordance and which it demands be attended to. Memes in this casting are a label for successful boundary object indexicals and lose their privileged status as replicators. Instead, the replicator status is ascribed to the environmental niches and the memes are their representatives, symbols, or semantic indexicals. [Note 1]

With this definition, memes are repackaged as symbols and their impact on management is not that of a viral contagion but rather as an indicator of success and change in environmental niches. If an environmental niche has an important managerial role, then paying attention to its symbols and affordances can also be important. Memes are stripped of their casual role and instead become semantic tokens capable of evoking ascribed meanings. It is the process of evoking and the efficacy of the meme as the trigger for attention, recall, and repetition of the ascribed meaning that give memes relevance to managers.

The argument herein [note 2] thus assumes that memes exist, but that their definition is not that of replicator but rather that of indexical token. The meme tokens are representatives of the environmental niche in which they flourish and about which they offer efficient communicative potential. Memes, it is argued, succeed when they are accepted and used as tools for the accomplishment of a communicative purpose. Memes fail when their ontic status itself becomes a focus. Memes have longevity only if they both succeed and serve as a useful tool for a successful environmental niche. Memes can be short-lived due to the failure of their communicative efficacy or the failure of the niche they represent or both.

2. Memes as Indexicals

Indexicals are concepts that we make use of nearly every day but, for most of us, they are unknown and unthought about. The dictionary or encyclopedia entries are actually of little help. Take this entry from the *Stanford Encyclopedia of Philosophy*:

Indexicals are linguistic expressions whose reference shifts from utterance to utterance. "I," "here," "now," "he," "she," and "that" are classic examples of indexicals. Two people who utter a sentence containing an indexical may say different things, even if the sentence itself has a single linguistic meaning. For instance, the sentence "I am female" has a single linguistic meaning, but Fred and Wilma say different things when they utter it, as shown by the fact that Fred says something false, while Wilma says something true. (Braun 2001)

Indexicals are words used to stand for a set of other words; that is, they function like an index on the stock market. The Dow Jones Industrial average, for example, stands for a basket of particular stocks and stands for many of us as an indicator of the market as a whole. Pronouns as described above are indexicals in that they stand for the noun and take on different meanings in different situations. "Where a word acquires its sense from the context in which it appears; in different contexts, it changes its sense" (Vygotsky, 1986).

In American society the most commonly heard indexical is the mythical "they" who do things to us or others. "Look at what they are doing now." Perhaps the second most popular indexical is "You know..., you know who I mean." Indexicals are often distinguished by the fact that their reference systematically varies with the context of usage. Indexicals offer a simple means of making, expressing, and communicating our references, and they are particularly useful when proper names or descriptions are either cumbersome or unavailable. Similarly, in interpreting someone's "that way" in response to a request for direction, one must be able to determine independently what direction the person is indicating.

One must discover what relations one bears to the indexical referents in order to locate and act on them, but there is nothing indexical about these relations themselves (Millikan, 1993). To interpret an indexical, therefore, is to establish what other items, entities, and representations it coincides with. By itself, it tells us neither about its contents — what it bears its adapting relation to — nor about its contexts; context determines the indexical's content, but context is not what content is about. As David Kaplan (1989) puts it:

What is common to [indexicals] is that the referent is dependent on the context of use and that the meaning of the word provides a rule which determines the referent in terms of certain aspects of the context. [Note 3]

2.1 Efficiency

Indexical language possesses a quality that Barwise and Perry (1983) call efficiency. This refers to the capacity of an indexical representation to refer to different individuals on different occasions. The efficiency of an indexical relates to the engineering quality of efficiency in the notion that the same symbol is capable of standing for a multiplicity of meanings — the greater the number of potentially stood-for meanings, the greater the efficiency of the indexical. In organizations, management frequently refers to the company, a team, a symbol, or mission, vision, and values as absolutes without being aware of their indexical content. Thus, despite the likelihood that an organizational symbol carries a multiplicity of meanings, managers might make use of such symbols as if the only possible referents are the ones conceived of by the manager him- or herself. Yet, it is possible by ethnographic observation for a careful outsider to discern at least some of the various referents summoned up by the use of these "unintended" indexicals in situ. Indeed, by such processes of observation a corporate ethnographer or anthropologist can reach tentative conclusions about the corporate culture and climate of the organization being observed.

Indexicals are situated. The use of an indexical succeeds when the combination of context and symbol evokes an intended meaning. The indexical provides a locating space into which many

variants of personalized and situated meaning can be ascribed, attributed, or devolved. This space is the container of which Prigogine first spoke when describing self-organizing systems. In the absence of such containers, self-organization is nearly if not totally impossible. In the arena of culture, the meme as indexical is a locator or referent affording the evocation of situated meaning. Efficacy of memes is determined by that evoking and the relevant situating.

The efficiency of indexicals means that they can break, that the context and situatedness that help to afford meaning to the indexical can stretch it beyond breaking points. When indexicals break or are challenged, they raise questions of boundaries, frames, and identities. While the challenges to indexicals can be very subtle, when they break they break the entire frame of how a situation is understood. Americans were made aware of this when Senator Jim Jeffords of Vermont switched his party affiliation from Republican to Independent (and thereby altered control of the US Senate). His speech of explanation was a discussion of his perceived limits to the indexical "republican." If memes are understood to be indexicals, then their success or failure is not marked by evolutionary inheritance but rather by the longevity of their efficacy. That longevity is in many ways determined by the situation and the meaning "carrying capacity" of the meme indexical.

2.2 Frames

Donati (1992) observes that people frame an object around which an issue revolves rather than the issue itself, and that the study of frames involves identifying how people understand an issue, rather than determining if they are "for" or "against" a proposition. Gratton (2000) notes, working to create a shared and coherent meaning in line with corporate aspirations demands an understanding of the current meanings within the organization. We strive to interpret our world, not simply by imposing structure but by translating events and developing frameworks for understanding.

Frames are patterns of organized information by which people make sense of the world. These "patterns," "schemas," or "frames" form part of the "discursive universe" in which people interact with each other. People learn frames as they learn to use a language fluently and as they learn the narrative structures and ideologies present in the cultures that use that language. When people encounter new information or a new experience, they make sense of that information or experience by fitting it into an existing frame. Nevertheless, people will generally be able to fit any given collection of information into multiple frames; though, at the same time, they will also tend to perceive information selectively, focusing on details that most readily fit into the frames they know.

As humans, we seek to solve problems as presented; we acquiesce in their frames. Indeed, we become prisoners of the frame. Shira White (2002) tells an illustrative story of such prisons: Scientists have done some fascinating and suggestive experiments with ordinary houseflies. If you capture and keep houseflies in a jar and then remove the lid after a few days, most of them will not fly away. In fact, they stay right where they are — inside the jar — even though they could escape if only they could see their way to freedom. But they seem "committed" to a lid that is no longer there. Psychologists have identified this phenomenon as "premature cognitive commitment." It is premature cognition in the sense that it occurs, more or less automatically,

before we are aware of or fully understand the stimulus. It is "commitment" because we are locked into a specific set of thoughts. Like the houseflies, we give up the freedom to choose once we become committed to the nonexistent lid. The first step in challenging a commitment is recognizing that you have made it in the first place.

The American philosopher John Dewey prefigured this situation in his 1934 book, *Art and Experience* (Dewey 1934):

No matter how ardently the artist might desire it, he cannot divest himself, in his new perception, of meanings funded from his past intercourse with his surroundings, nor can he free himself from the influence they exert upon the substance and manner of his present being. If he could and did there would be nothing left in the way of an object for him to see.

2.3 Boundaries

The symbols and signs that we use to express meaning or hope will evoke meaning in others not only as communication devices but also as boundary setters. The words and the meanings that they evoke set up boundaries with regard to our ability to attend to, cognize, or be aware of aspects of our situation.

According to what can loosely be described as "boundary theory" (*Michaelsen & Johnson, 1997; Nippert-Eng, 1996a, b; Zerubavel, 1991*), individuals create and maintain boundaries as a means of simplifying and ordering the environment. "Mental fences" (*Zerubavel, 1991: 2*) are erected around geographical areas, historical events, people, ideas, and so on that appear to be contiguous, similar, functionally related, or otherwise associated. The process results in the creation of slices of reality domains that have particular meaning for the individual(s) creating and maintaining the boundaries. "Home," "work," and "church" are examples of the social domains created by boundaries (*Nippert-Eng, 1996a*). The boundaries are real in the sense that the individual perceives them as such and acts as though they are real (cf. *Weick, 1979*).

Although a given domain may be socially constructed and more or less institutionalized (e.g., people share a general consensus on what home means), *Nippert-Eng (1996a, b)* has shown that the boundaries around that domain are somewhat idiosyncratically constructed (e.g., one person allows home to cross over into work, whereas another keeps them separated). Further, by circumscribing domains, boundaries enable one to concentrate more on whatever domain is currently salient and less on other domains. (*Ashforth et al., 2000*)

These boundaries can be triggered by repetition and word choice. *Gould (2000)* suggested that they were triggered by "canonical stories" — the shorthand for which are often labeled by the media as "memes."

The vertebrate brain seems to operate as a device tuned to the recognition of patterns. When evolution grafted consciousness in human form upon this organ in a single species, the old inherent search for patterns developed into a propensity for organizing these patterns as stories, and then for explaining the surrounding world in terms of the narratives expressed in such tales. As for mind, even when we can attribute a pattern to conventional nonrandom reasons, we often

fail to apprehend both the richness and the nature of those causes because the lure of canonical stories leads us to entertain only a small subset among legitimate hypotheses for explaining the recorded events. Even worse, since we cannot observe everything in the blooming and buzzing confusion of the world's surrounding richness, the organizing power of canonical stories leads us to ignore important facts readily within our potential sight, and to twist or misread the information that we do manage to record. In other words, and to summarize my principal theme in a phrase, canonical stories predictably "drive" facts into definite and distorted pathways that validate the outlines and necessary components of these archetypal tales. We therefore fail to note important items in plain sight, while we misread other facts by forcing them into preset mental channels, even when we retain a buried memory of actual events.

Word choices afford the possibility of new meanings, new analogies, and new insights, which, in turn, can lead to new or next activity. As people share framed information, they need not refer to all aspects of a frame directly to communicate which frame they have adopted to make sense of the information. Instead, they need only make reference to one dimension of a pattern to enable hearers or readers of their text to recall the whole frame. This evocative "power" is one of the attractive aspects of the meme concept. By viewing signifiers of meaning such as memes as mediums with a context dependence, we can see how the frames that result from word choice can work to limit or expand the very possibilities that we recognize as being afforded by our current situation. Word choice matters as a delimiter of possibility space as well as a means of communication. This provides the context in which mechanisms of memes operate.

3. Mechanisms [note 4]

A word in context means both more and less than the same word in isolation: more, because it acquires new context; less, because its meaning is limited and narrowed by the context. The sense of a word... changes in different minds and situations and is almost unlimited. It is not merely the content of a word that changes, but the way reality is generated and reflected in a word. A complex is a word which does not function as a carrier of a concept but rather as a family name for a group of objects belonging together not logically but factually. (Vygotsky, 1986, page 245)

It is through language that we construct reality. With words we define, shape, and experience. Without the words to think, communicate, experience, or understand our lives would be very different from what they are. Words expand our consciousness but also limit us as we can only fully experience those things that we have the words for. Language provides the framework through which we perceive, experience, and act. As language constructs reality, so symbolization constitutes objects. Symbolization constitutes objects not conceptualized before, objects which would not exist except for the context of social relationships wherein symbolization occurs. Language does not simply symbolize a situation or object which is already there in advance; it makes possible the existence or the appearance of the situation or object, for it is a part of the mechanism whereby that situation or object is created. (Mead, 1934)

One example of this is the word "set," which has more than 100 meanings. The multiplicity of such meanings is the substrate for the mechanisms of imitation, transmission, and evolution that are "normally" ascribed to memes. Words evoke families of meanings. In Lissack and Letiche

(2004), these families of meanings are referred to as a glom. (Vygotsky, in his work, used a word that is usually translated as "complex." Lissack and Letiche opted for "glom" so as to avoid confusion.) The multiplicity of meanings implicit in a glom allows, when each such meaning is viewed as a medium, new possibilities for action. Vygotsky distinguishes between more primitive gloms — a word that does not function as a carrier of a concept, rather as a family name for a group of objects belonging together not logically but factually — and higher-level concepts. First come the gloms, and it is when abstracted traits are synthesized anew and the resulting abstract synthesis becomes the main instrument of thought that a concept emerges (Vygotsky, 1986).

3.1 Gloms versus Indexicals

Gloms differ from indexicals. Gloms are primitive collections of families of meaning. Thus, when a child is learning about daddy going to the office, an entire realm of experience is built into the glom of "daddy's office," "office," and "going to the office." Only later will the child be able to separate the primitive wealth of experiences into distinguishable parts and associate a socially acceptable label with some of those parts to better "bound" the concept of daddy's office (the subway trip and its associated people and smells may be in the glom but will have been removed from the concept). By contrast, indexicals have no meaning independent from the situated context in which they are evoked.

Because indexicals have no inherent meaning independent from context, the use of an indexical is constrained by the variety of contexts in which it is deployed and the multitude of meanings from which the interplay between context and indexical is required to distinguish. The effective indexical serves as a medium to evoke meaning. The ineffective indexical will instead call attention to itself with the demand for further clarification. In essence, its ability to carry meaning will have been compromised. The overloaded indexical reveals itself via a lack of transparency to its medium-serving (medionic) functions and the implicit question of "this or that?" When something new is encountered (a perturbation) or emerges at another level, the prior sense of clarity in the fundierung between indexical and situation can break down, much like the tragedy of the commons as described by economists. When the context does not evoke a clarity of meaning and multiple meanings are possible, evoked, and present, the indexical is broken and what has been called a glom has been evoked instead.

The important observation is what Vygotsky says occurs when there is dissonance between the understood meaning of a concept and new input, whatever it might be. When a concept breaks down there is reversion back to the glom. That reversion allows for change. The dissonance produced thereby forces a reversion in the perceived meaning of the word. Context dependence takes over. "It is not merely the content of a word that changes, but the way reality is generated and reflected in a word" (Vygotsky, 1986, page 213).

3.2 Multiplicity of Meanings

Inherent in the multiplicity of meanings is the recognition that only one meaning will be primary within the context of a given situated activity. That primary meaning will not be the solely representative meaning, but will take its primacy from the context. When there is coherence

between the situation and the meaning, the word choice will display a transparency with regard to medionic function. When that coherence is weak or absent, the very act of picking a label will demand some amount of attention. What coherence there is about the meaning, if it is to exist, would be forced to overcome or overwhelm such attentional demands.

The multiplicity of meanings undercuts the effective use of analogy as the word tokens of memes. Metaphors and analogies create constraints by focusing attention on that which is like and the resulting tendency by the user to attempt to justify the analogy. These constraints may not be readily apparent when the weakness of the analogy or the affinity is being exposed. Analogy involves inexact likeness. Butchvarov (1970, 1979) distinguishes between conceptual clarity and conceptual distinctness. Via analogy we can see the relative position as far as distinctness but can never achieve clarity. The former is a location in conceptual space and can be determined by noting similarities and differences between the entity being compared and other entities in conceptual space. However, clarity involves the content of the entity itself. It can be modeled, but the limitations of the model must be noted. Understanding is the desire for clarity, not merely distinctiveness. There is a remainder between the two. While categorization can suffice on distinctiveness, understanding cannot.

When we use analogy we are calling attention to some "like aspect" of two entities (call them source and object). If we were to dialogue with full disclosure about the analogy — this is similar, this is different; notice how the similars might react in situation x and contrast that with the differences, and so on — we would lose the shorthand and efficiency evoked by the analogy. Thus, we tend to allow our use of analogy to emphasize similarity over difference and substitution over care. In practice, when we assert that a is analogous to b, we often then make use of b as a label or category into which a falls. Affording such primacy to the similarities is to grant supervenience to the characteristics of the source at the expense of a fuller description of the object. When the similarities of a metaphor or analogy are allowed to supervene such that the analogy source is substituted in meaning for the description of the object, mistakes happen, possibility spaces are misconstrued, retrospective sensemaking might not make sense, and taken-for-granted fundierung relations may hide nasty surprises. To the extent that coherence is perceived, it may be based on fantasy. Indeed, much of the Internet/telecom bubble of the late 1990s seems to have been fueled by the supervenience of the characteristics of an "insatiable appetite" associated with convenience and newness over the demands for infrastructure, use, and value. The same pattern has been displayed by many of the bubbles documented in the history of economics.

3.3 Conceptual Slippage

Word choice and metaphor use allow for the emergence of new memes, the replacement of memes, and the death of memes via a concept that Douglas Hofstadter (1995) has labeled "conceptual slippage." In essence, the use of a metaphor or analogy evokes a glom of meanings. Each such use of metaphor is a perturbation to the existing self-referencing system (be it an individual, the organization, or some part thereof). The perturbations (please notice the plural) caused by the glom or gloms interact in multiple dimensions with the self-referenced core. As this series of interactions and resultant emergent behavior self-organizes, the principle of "least action" takes over. The basin of attraction that is the least demanding of energy is likely to

determine the "winning" meaning. The least-action principle suggests that the energy demands of attention or of the carrying of a full description are likely to be superseded by the efficacy of using an analogy, a label, or a name, even if incorrectly. Thus, one concept can slip to another via the energy demands of the least-action principle. The "whatever" of the current teen does not mean permission, tolerance, or inclusiveness, it means indifference — though most over-40s would not recognize that except after a series of painful experiences.

Thagard and Nerb (2002) make a similar claim to Hofstadter's conceptual slippage in describing emotional gestalts:

Thagard (1996: *Ch. 11*) described how dynamical systems theory can be applied to psychological phenomena by means of the following explanation schema: Human thought is describable by a set of variables. These variables are governed by a set of nonlinear equations.

These equations establish a state space that has attractors. The system described by the equations is chaotic. The existence of the attractors explains stable patterns of behavior. Multiple attractors explain abrupt phase transitions. The chaotic nature of the system explains why behavior is unpredictable. In the language of dynamical systems theory, the perceptual system has two attractor states, and the gestalt shift involves a phase transition from one attractor to the other. Analogously, we might think of an emotional state as a gestalt that emerges from a complex of interacting environmental, bodily, and cognitive variables, and think of emotional change as a kind of gestalt shift... Emotional gestalt shifts occur when changes in representations and their valences generate a new array of acceptances and valences that maximize constraint satisfaction differently from before. Through parallel constraint satisfaction, this shift may alter the acceptance status of other propositions.

When an emotional gestalt occurs, so too might conceptual slippage. Both undercut the effectiveness of a meme set in a new context.

Fauconnier and Turner (2002) go further in that they not only look for a slippage in conceptual meaning, but also for the activation of a new meaning. This is an extension of the emotional gestalt argument.

In any theory of meaning, activation does not come for free. The existence of frames, knowledge, experience, scenarios, and memories does not come for free. Ease of activation and degree of entrenchment by themselves impose very strong constraints on the imagination and the use of language. Linguists, logicians, and, for the most part, even psychologists tend to focus on the entrenched cases, which are already built and usually easy to activate. When only the rigid and entrenched patterns are used, meaning becomes predictable based on the mapping schemes and those patterns... Blends arise in networks of mental spaces which they call conceptual integration networks. Conceptual integration networks can have several input spaces and even multiple blended spaces. In conceptual integration, there is partial matching between input spaces of many kinds: connections between frames and roles in frames, connections of identity or transformation or representation, analogical connections, and metaphoric connections. In blending, structure from two input mental spaces is projected to a new space, the blend. Generic spaces and blended spaces are related: Blends contain generic structure captured in the generic

space but also contain more specific structure, and they can contain structure that is impossible for either of the inputs. Similarly, not all elements and relations from the inputs are projected to the blend. Thus, emergent structure can arise in the blend that is not copied there directly from any input. (Fauconnier and Turner 2002, page 168).

Blends, emotional gestalts, and conceptual slippages are all evidence of the least-action principle (lower energy expenditure) at work.

3.4 Least-Action Principle

Lower energy expenditure is the driving pursuit in the information space world (cf. Boisot, 1995). In Vygotskian terms, a group and its members begin with some existing set of concepts and they encounter change. The encounter reduces some of the concepts to the status of gloms, and in such a status, the possibility arises for new conceptual understanding to emerge. This understanding will be influenced by the metaphors and analogies available to label the gloms, for in the adjacent meanings implicit in the metaphors is the potential synthesis represented by the new concept. The premises of least action suggests that a context-dependent glom is an efficient vehicle (in the same manner that Perry and Barwise suggest that indexicals are efficient), provided that supervenience is possible. This is because we use words as tokens and allow context to evoke meaning from among the gloms represented thereby. If supervenience is possible, then such evoked meanings are triggered by the situated activity in which they occur. By contrast, gloms will not work well in a system that is dependent on representations, reductions, and causality. In such a world, evoked meanings become reified and are carried across new situated activities. Dissonance from the mismatch is the likely result.

To a group member, context includes ongoing change — which then disrupts the shared-context content of existing codification and disturbs the agreed meanings of abstractions. A key least-action observation is that personal coding of meaning is transformed within an organization into institutionalized codification, so as to both maximize the value of shared meaning and minimize the need for the energy expended to transmit shared context. Emergent change erodes the ability of codification to hold. In the absence of an offsetting response to this erosion, institutional codification recedes to personalized coding, and the ability of common abstractions to transmit shared meaning deteriorates. Concepts become gloms. Such disturbances can have an emergent character that itself is disturbing, because the cumulative effects thereof cannot be predicted or planned for. This lack of prediction or planning poses a threat to coherence. And coherence preservation is another energy-conserving action within the information space.

Thus, we have a mechanism for meme success and failure. Emergent change occurs in the environment. In Vygotskian terms, the dissonance introduced by emergent change forces previously accepted concepts to recede to gloms. Uncertainty of meaning is introduced. For our purposes, uncertainty can be regarded as a label better defined as the inverse of one's propensity to act (Dretske, 1981; Fransman, 1994). Given uncertainty's threat to coherence, organizations must find a way to combat its increase, for uncertainty is a significant energy drain running counter to the principle of least action. Increases in uncertainty can be attributed to loss of identity, to a perceived need for more and "better data," and to an increase in the perceived threat from taking an incorrect action.

This translates into the lack of a well-understood model of the possibility space and thus the substitution of a need to search for a willingness to act. If identity is to be preserved, then there must be an offsetting emergent response to rebuild context so as to replace the content lost to uncertainty (i.e., that which was contained in the institutional codifications and abstractions that have now encountered disconfirming notions and been forced to revert to the more primitive gloms of meaning). Success is related to the evolution of the ideational niche for which the meme is a token. If that niche has failed, so too will the meaning-evocation powers of the token.

The successful meme is one whose indexical quality can bridge both the old context and the new, such that the users of the meme token can dialogue about the meanings evoked by that token without asserting incommensurability. The unsuccessful meme is one whose indexical quality cannot bridge the gap between contexts and thus cannot make the transition to new context and new situation.

4. Implications

We need to do memetics to demonstrate when, where and how memetics has a relative and relevant advantage over social science devoid of memetics. The future of memetics will not be decided by those talking about memetics, whether grand theorising or armchair philosophy about the evolution of culture, history, consciousness or how we think, but will be decided by those doing memetics and demonstrating its relevance. (Hales & Marsden, 2002)

A memetics that accepts memes as indexical catalysts and tools can demonstrate the advantage that Hales and Marsden seek. Such a memetics allows for study of the content of information and its use, with a focus on processes and mechanisms vastly different from what passes today as information science, knowledge management, or linguistics. This is not a memetics that studies the evolution of memes per se, for the ontological status of memes is changed within it.

However, such a memetics can demonstrate relevance, advantage, and application.

For example, if this approach were adapted to an extension of Salingaros and Mikiten's (2002) exploration of modernism as an architectural meme, the discussion would explore the environmental niche in which the qualities laid out for the success of the modernism thrive. This would be followed by an exploration of what potential risks for the success of the meme lie within and without that niche, and what factors of the meme and/or the niche contribute to its ongoing resilience. Once the risks and resilience factors have been so identified, they can be mapped to other domains and compared with the success/failures of other memes both within and without the architectural domain. This seems far more fruitful an approach to making social science advances than the mere mapping of modernism in architecture as a meme (a mapping that allows critics to reply "So what?").

Edmonds' (2002) three challenges can be answered by this revised form of memetics. For example, his first challenge argues that a "conclusive case study" would "clearly demonstrate that there is at least one cultural process that is of an evolutionary nature, where 'evolutionary' is taken in a narrow sense." If the requirement that it is the meme that must be of an evolutionary nature is dropped, then Edmonds' challenge is easily fulfilled. Anthropology and sociology can

document hundreds of cultural processes that are evolutionary and many of these will have a history of successful memes associated with them. What is difficult for meme as replicator is much easier for meme as indexical catalyst.

Lissack and Letiche's forthcoming *Coherence Emerges: A Complexity Theory of Organization* (2004) is an example of work that meets Edmonds' second challenge. So too does much of the case-study work on organizational symbolism. Edmonds' third challenge is perhaps incommensurate with the revisions suggested above. Memetic processes of the catalytic indexical variety are easily found and documented in the "real" world and are not in need of "simulation." Such "real" examples should, in any case, be considered as a firmer foundation for an applied theory than simulations could provide. Memetic processes of the catalytic indexical variety also seem to address many of the concerns raised in Bloch (2000) and Kuper (2000).

This redefinition of memes recognizes that they are efficient tools for evoking particular affordances to be attended to in situ. Such a definition is consistent with theories of niche construction. This article suggests that Dawkins created an indexical (meme=gene) and it has exceeded its carrying capacity and thus lost its efficacy. Worse, that indexical is evoking images and affordances that stand in the way of the memetics field making true progress. It is time to recognize that ontic status has been misplaced. Memes need a new meme: meme as catalytic indexical.

For managers, memes defined as catalytic indexicals raise the potentialities offered by other catalysts — the provisioning of an environment with a catalyst can afford the possibility of a transformation that is much more difficult than without the catalyst's presence. Memes would be studied for their catalytic roles and managers would be taught sensitivity to the conditions that aid and hinder the evolution of such catalysts.

As catalytic indexicals, memes can be meaningfully assigned explanatory and causal roles — the very ingredients that Edmonds claims memetics needs, and the qualities that managers are often seeking.

Notes

1. This notion does not conflict with the definition of meme in the Oxford English Dictionary: An element of a culture that may be considered to be passed on by non-genetic means.
2. An application of this argument is forthcoming in Lissack & Letiche (2004).
3. Cf. T. Kapitan's "Autonomy of indexical reference" and related works can be found at: <http://www.soci.niu.edu/~phildept/> and G. Nunberg's "Indexicality and deixis" (1993) and related work at: <http://www-csli.stanford.edu/~nunberg/linguistics.html>.
4. Much of the mechanism argument was first developed in Lissack & Roos (1999) and has been expanded in Lissack & Letiche (2004).

UNITS, EVENTS, AND DYNAMICS IN MEMETIC EVOLUTION

By
Aaron Lynch

[NOTE: equations reproduced flawed]

Abstract

An evolutionary recursive replicator theory of mental/brain information is presented. With all replicator theories resting at least tacitly upon the fundamental notions of causation and of calling two or more entities "the same" with respect to an abstraction, the concept is rendered explicit in defining the terms "mnemon" and "meme". It is argued that memetics may have no "absolute" system of memory abstractions much as physics has no absolute coordinate system (framework of space-time abstractions). A symbolic calculus of mnemon conjugations and replication events is introduced. The term "meme" is given a technical definition, and reasons are offered for avoiding more expansive definitions. Arguments that meme sets are generally only partially ordered then provide a formal reason for rejecting mnemon "size" as a crucial element in defining the word "meme". Differential equations are developed for meme host population versus time in a two-meme system, modeling the dynamics whereby events at the individual level give rise to trends at the population level. This lays a foundation for computerized simulations and the falsification or validation of specific memetic hypotheses, and for testing population memetics theory with animal experiments. As memetic hypotheses generally involve observable communication events, they are found to have stronger empirical standing than hypotheses involving unidentified genes. Mechanisms of creativity as a population phenomenon are examined, with memetic analysis yielding a novel explanation for the temporal clustering of independent co-creations. Creation and propagation are integrated into a theory of evolution by variation and natural selection of memes.

KEYWORDS: Meme, mnemon, evolution, replication, abstraction, transmissivity, receptivity, longevity, recursive algorithm, differential equation.

1 Introduction

In the last chapter of his 1976 book *The Selfish Gene* [3], Richard Dawkins introduced the term "meme" for lay audiences as "a unit of cultural transmission or a unit of imitation". He went on to explain that this covers ideas, tunes, fashions, and other information stored in brains. In *The Extended Phenotype* [4] Dawkins more explicitly clarified that "a meme should be regarded as a unit of information residing in the brain"¹. I have since taken this meaning of the word "meme" and refined it into a more technical definition suitable for symbolic and mathematical analysis [11]. In arguing that meme theory is not only sound but also broadly unifying, my book *Thought Contagion* [12] went on to use a great variety of non-technically presented examples to show the relevance of meme theory to important human phenomena. Yet the further development of strong theoretical treatments, formal definitions of terms, mathematical analyses, discussions of empirical methodology, and criteria for falsifiability remain subjects of interest among hard core

scientists. This paper revisits the theoretical issues and the underlying philosophy of science, and elaborates on topics of empirical methodology and falsifiability.

2 Non-Metaphoric Memetics

In memetics, organic evolution, biological contagions, plasmids, and computer viruses have served as metaphors for the spread of ideas. In principle, however, someone could have offered a treatise on the replication, proliferation, and evolution of ideas long before Darwin's work on evolution, Pasteur's work on microbiology, Mendel's work on genetics, or Turing's work on automata. Indeed, that treatise might even have afforded metaphors to these other disciplines had it appeared by the early 1800's. On this planet, though, the history of science has its social and information fields drawing metaphors from biology rather than the other way around.

Like all metaphors, the ones linking beliefs to organic and software contagions have their limitations. Metaphors make powerful literary and explanatory devices, and can render a potentially dry and abstruse subject interesting and readable. They also serve to spark important new scientific insights. But relying too heavily on them can lead to bad science. It makes sense, then, to recast the core concepts of memetics theory in language that does not depend on analogies to the biological or computer sciences. The analysis is drier, but it does formally illuminate some ways that memes depart from strict analogy to other replicators. It also provides some philosophy of science behind memetics theory while offering a stronger platform for mathematical and empirical investigations.

3 Units of Memory Replication

Defining the "unit of imitation" is as critical to memetic evolution theory as defining the units of heredity was to genetic evolution theory. The gene's definition developed as empirical investigations led away from the hypothesized inheritance of acquired characteristics to the biochemical sequencing of DNA strands. The universal code of these strands constituted a natural "language" upon which scientists based their own more symbolic and abstract language. Yet for the evolution of ideas, no equally understood concrete language has been discovered. Science has achieved no direct observation of the neural encoding of ideas, which might have provided us a precise language for discussing ideas. Indeed, even if we knew in principle how to express the ideas of a single person in terms of neurons, synapses, etc., the description would likely be prohibitively complex. Moreover, as Dennett points out in *Darwin's Dangerous Idea* [5], it would be flabbergasting to find that the brain-cell complex that stores an idea in one person is the same as or very similar to the brain-cell complex that stores the idea in all who have that idea². So instead of language based on a concrete mechanism of information storage, we must settle for an abstract representation of the information stored. Thus, memory abstractions form the basis for memetic evolution theory.

Most people use abstract representations of memory content on a daily basis to discuss ideas. When we say that two people have "the same" idea, we do not use "sameness" to mean equality in every concrete detail, or else we could never correctly say that two people have "the same" idea. As Dawkins [3] put it, "If this were not so, then almost any statement about two people agreeing with each other would be meaningless". What we mean by saying that two people have

"the same" idea is that one person's idea has at very least one quality in common with the other's idea. Perceiving two people to have "the same" idea involves abstracting out a set of common qualities. So saying that two people's ideas are "the same" only means that they are in some way "of the same kind".

This ability to say that two people have the same idea lies at the foundation of the notion of a "replicating idea". When an idea "replicates", it acts to produce or preserve ideas that we call "the same idea". The resultant ideas can for now be called "self-replicated" ideas. To be a self-replicated idea means not only to have resulted from a given idea, but also to be "the same" as that idea. Specifically, it means meeting some abstract, observer-defined criterion for sameness. Self-replicated ideas are not all exact replicas of their originals. A wide range of ideas may result from each self-propagating original. An observer just selectively lumps these proliferated ideas along with their original(s) into a set, using an abstract inclusion criterion.

As an example, the belief that "abortion is wrong" has a wide range of different meanings to different people. The range includes people who regard abortion as merely unethical to those who see the "morning after pill" as a high felony. So, although the belief varies greatly from person to person, its occurrences are all "the same" in the limited respect of fitting the above definition. Encountering a range of such beliefs in actual people, one "abstracts out" a common element running through all of them. On writing out a definition of this abstracted common element, or sameness criterion, one can proceed to use it for natural selection reasoning.

The abstraction could just as well be more general or more specific, depending upon our interests. A memeticist might, for instance, choose the more specific belief "abortion is a mortal sin". Then many quantitative variables involved in its natural selection would differ from those associated with the broader definition. First, the more restrictive definition would almost certainly identify a smaller host population. Second, when the hosts communicate their belief to friends and family, a likely smaller fraction of listeners will become new hosts per exposure. This is because any listeners who go away newly convinced that abortion is merely unethical no longer count as new hosts. Becoming a host of the more restrictively defined belief takes more of what Dawkins [3] calls *copying fidelity*. Third, once a host, one may do less "ideological wavering" before being counted as a drop out. That is, remaining the host of a more restrictively defined belief takes more preservation fidelity. So changing an idea's definition can make a big difference in the evolutionary phenomena identified with it.

4 Other Propagating Items

Many psychological phenomena other than ideas can be observed to self-replicate. These include certain habits, attitudes, class identities, cognitive associations, education, emotional dispositions, addictions, and even neurotic and psychotic symptoms.

All these traits may be broadly classified as human memory content. This category is more general than the word "idea" or even "memory" usually connote. It includes everything in the fairly broad meaning of "memory", as defined in Merriam Webster's Collegiate Dictionary, 10th edition: "the store of things learned and retained from an organism's activity or experience as evidenced by modification of structure or behavior or by recall and recognition". Thus, the

principle abstractions manipulated with memetics theory are memory abstractions, or *mnemons*³. Mnemons do not include inanimate propagating items such as chain letters, Bibles, etc. Nor do they include traits considered genetically instinctual.

Using mnemons helps to standardize the measurement of propagation in terms of a host count. Thus, a chain letter or the copying machine duplicating it do not count as hosts, but the person photocopying the letter does. The relationship of artifacts to mnemons is discussed later. If a mnemon resides very redundantly in someone's brain, that person still counts as only one host and one mnemon instantiation. The number of duplicates of a memory item in one brain is not currently measurable, so it escapes further treatment in this article.

5 Representing Mnemons Symbolically

Mnemons can be represented conveniently with symbols such as "*A*", "*B*", etc. Thus, we can call the hell belief mnemon *A*, the imminent doomsday belief mnemon *B*, and a combination of mnemons such as the hell/imminent doomsday combination "*A*B*". The "*" indicates that *A* and *B* are instantiated in the same host. Extending this concept, one can represent a whole system of mnemons as "*A*B*C*..*".

Symbolic expressions can also represent mnemon replication much the way chemists represent chemical reactions. Thus, the hell belief's non-parental conversion propagation may be represented as $A+\sim A2A$. This expression is read as "Host of *A* together with a non-host of *A* yields two hosts of *A*". (The "~" indicates only non-host of *A* status, and does not of itself imply hostship of a contrary belief.) The two hosts on the arrow's right are the same two people as on the left side, one of whom is converted from non-host to host status. (The word "horizontal" may also be used, to describe this kind of non-parental event, as long as it is not taken to refer only to transmissions between people of similar social status.) The mnemons on the left side of the arrow are called the input mnemons, and those on the right, the output mnemons.

A transition such as $A+\sim A2A$, realized in particular people at a particular time, constitutes an evolutionary event in the ideosphere⁴. Other evolutionary events include: $A\sim A$ (host of *A* drops out), $\sim AA$ (non- host independently forms *A*), $A0A$ (host of *A* dies), and $2A2A+\sim A$ (two hosts of *A* have a baby non-host of *A*).

Even multistage evolutionary events are handily represented by this system. For instance, the childbirth event can be extended to the form $2A2A+\sim A3A$. (Two hosts of *A* have a baby and then spread their *A*-mnemon to the child.) A more complicated possibility is $A+\sim AA+2\sim A \quad 2A+\sim A$. (Host plus non-host of *A* have a baby who later adopts the *A*-mnemon from the *A*-host parent.)

Some multistage events are best represented by two or more diagrams. For example, if two hosts of *A* have a baby non-host and then have their local Sunday school teacher instill the *A*-mnemon in the child, one would represent it as two events: $2A2A+\sim A$ (the birth) and $3A+\sim A4A$ (the catechism). In the second event, the three input *A*-hosts are the teacher and the two parents (who select the teacher). Representing the events separately (instead of as $3A3A+\sim A4A$) conveys with greater clarity that the teacher's role happened only after the birth. Many two stage events pertain

to the parental replication because that mode generally involves both having and training children.

6 Complementary Mnemons

Treating $\sim A$ as a mnemonic along with A may seem rather strange. People labeled " $\sim A$ " may be called $\sim A$ -mnemon hosts or A -mnemon non-hosts. (A and $\sim A$ are called complements of each other.) But can a person's lack of the A -mnemon justifiably be called a mnemonic itself? It sounds like saying that nothing is something.

The meaning of the term "mnemon" provides an answer to this question. Mnemons are merely memory abstractions. As such, a negatively defined mnemon which only states what a person does not have is just as much of a memory abstraction as is a positively defined mnemon. Saying that someone "has" or "hosts" a mnemonic like $\sim A$, really means that the person satisfies the definition of the particular memory abstraction (i.e., the person instantiates the abstraction). This is what we mean when we say that a person "hosts" a positively defined mnemon. The only difference is that the term "memory" is expanded in a way that somewhat resembles its usage in computer science: it now includes some (partly) "empty memory" states that are not *specifically* determined by genetically based instinct.

Negatively defined mnemons can also self-propagate, as with the childbirth event $2\sim A3\sim A$, where A is a knowledge-of-birth-control mnemon. (One might define this mnemon functionally as knowing how to use at least one of some particular list of methods.) Because $\sim A$ -hosts have fewer birth control options than do A -hosts, the $\sim A$ -mnemon enjoys a greater quantity-parental replication advantage. Nonetheless, the A -mnemon has done very well in modern times, largely since people can be taught about birth control far more easily than they can be made to forget about it. Since proselytizing it is impossible, the $\sim A$ mnemon depends on parental events that occur just a few times per generation. The A -mnemon, on the other hand, proliferates by non-parental conversion for various reasons, including both the sexual and humanitarian motives of its hosts. So both A and $\sim A$ self-propagate, leaving us no choice but to consider the propagation of both a positively defined mnemon and a negatively defined mnemon in investigating this example.

Incidentally, $\sim A$'s parental propagation does not conform to the tendency, mentioned earlier, for the parental replication mode to involve multistage evolutionary events. People are born with $\sim A$, so that giving birth and "imparting" the mnemon are actually the same event. After birth, the parents can at most act to preserve $\sim A$ in their child.

7 Mnemon Combinations

Multi-mnemon events describe phenomena like idea alteration or recombination too complex to represent with one complementary mnemon pair alone. For example, forming the hell/imminent doomsday pair by recombination can be represented as $A*\sim B+\sim A*BA*\sim B+A*B$, where A = the hell mnemon and B = "doomsday is imminent". In this event, a person with only the A -mnemon spreads it to someone with only B , so that the latter person now has both A and B . This new combination may very well spark some new ideas in the $A*B$ -host. He might experience the

event $A*B*\sim CA*B*C$, where C is the belief that "I must urgently spread my faith to others because it may soon be too late!" Consequently, he may repeatedly play the leading role in the event $A*B*C+\sim A*\sim B*\sim C2A*B*C$. A , B , and C act cooperatively here to bring about their collective propagation.

Mnemons A , B , and C are all rather "unpleasant" ideas, so it does not seem too surprising to find them propagating cooperatively. Yet in the real world, these three propagate cooperatively with a very "pleasant" mnemonic D : "Love your neighbor as yourself". $A*B*C*\sim D$ motivates its hosts to spread their faith only to those "unbelievers" that they really care to see saved from hell. In marked contrast, $A*B*C*D$ hosts should be motivated to spread their faith to any unbelievers they should happen to meet. So the combination of mnemons probably spreads more vigorously due to the inclusion of the D -mnemon.

When mnemons propagate synergistically as do A , B , C , and D , they may propagate primarily as a set rather than individually. In such cases, the set may be usefully defined as one mnemon. Thus, one might define $E=A*B*C*D$ and consider E to be a stable, propagating mnemon in its own right. This approach can sometimes be used to study very large ideological systems, such as religious and political doctrines, by treating them as single (but lengthily defined) memory abstractions. The propagation events, however, often contain many intricate stages.

Moreover, in specifying mnemon " X " by an equation like $X=A*B*C*...$, one runs the risk of specifying so many "little" constituent mnemons that no one person ever actually has all of them. Mnemon X would then be a useless abstraction. This symbolic method allows its own hosts enormous freedom to specify their preferred abstractions, yet writing down symbols does not guarantee all those abstractions to be useful in studying the real world.

8 Competing Mnemons

Competition rather than cooperation characterizes many interacting mnemons. A mnemon competes against its complement in the knowledge-of-birth-control case mentioned above. The two complementary mnemons each "armed" with distinct replication advantages "struggle" for host population.

Yet more heated than this competition, at least in some nations, is the competition between moral stances on the subject. Personal morality, after all, has a greater bearing on an adult's use or non-use of various methods in a society where birth control information is highly available. Moreover, morality strongly influences the parental decision to actively instruct children on birth control or to actively obstruct their learning on the subject.

So in addition to the knowledge-of-birth-control mnemon (mnemon A), we should also consider mnemon B , the moral acceptance of practicing birth control, and mnemon C , the belief that birth control is immoral. Here people are born with the $\sim A*\sim B*\sim C$ combination, but they never end up simultaneously having B and C later on. This is because B and C are *contrary*, as distinct from complementary mnemons. Since they are mutually exclusive, they are destined to have a competitive rather than a cooperative relationship in the population. The B mnemon is favored by a high occurrence of the non-parental conversion event $B+\sim B2B$, while C is favored by a high

rate of the parental event $2C \rightarrow 2C+\sim C3C$. B benefits spreads due to the same kind of sexual and humanitarian motives for spreading it as those shown by the A mnemonic. C spreads "parentally" because people who believe that birth control is immoral do tend to have more children. Economic motives for spreading and adopting the two mnemons also exist, and vary among situations. Additionally, the drop out rate of children raised as C -hosts varies with population homogeneity, media exposure to B , etc.

9 Homogenic and Heterogenic Events

The birth control example as treated so far fails to acknowledge people's ability to independently invent or re-invent moral decisions on their own. People are portrayed as acquiring mnemons only by copying them from others or by being born with them (as in the case of negatively defined mnemons).

To remedy this omission, consider the cases of two students who learn about birth control methods and then make moral judgments based on what they have learned. The first decides the practice is morally acceptable ($A*\sim BA*B$). The second decides it is not ($A*\sim CA*C$). Of course, people can make moral judgments without knowing birth control methods, but in this case our two hypothetical students judged only upon gaining the knowledge.

So one mnemonic precipitates the formation of another mnemonic, instead of just a new copy of itself. Mnemons that do this are called *heterogenic*, or "other-forming". The corresponding events, such as $A*\sim BA*B$, are called *heterogenic events*. The other type of event, which produces copies of input mnemons, is appropriately called a *homogenic*, or "same-forming" event. The input mnemonic that gets copied is called a *homogenic mnemonic*.

Mnemonic event diagrams and terminology now acknowledge that people can form opinions without simply copying others' ideas. Yet on many topics, people copy more ideas than they either originate or "re-originate". For many beliefs, such as the birth control taboo, homogenic formation far outweighs heterogenic formation in its overall occurrence rate. The reason is that homogenic events have the tendency toward self iteration while heterogenic events do not. Generally speaking, anything that increases the availability of the input mnemons will increase the expected frequency of the event. Homogenic events, such as $2A2A+\sim A3A$, increase their own input mnemons. So they often tend to increase their own likelihood of recurring. When they do, they exhibit the *recursion principle*, which can lead to vast increases in mnemonic prevalence. In contrast, heterogenic events, such as $A*\sim BA*B$, actually decrease their own input mnemons by one with each occurrence. This tends to decrease the heterogenic event's recurrence rate. Yet the independent thinker can pass the new, *heteroderivative* mnemonic along, resulting in homogenically formed, or *homoderivative* mnemons. So after the first few heterogenic formations of the birth control taboo, the formation of new taboo hosts tends to become rapidly predominated by recursive, homogenic events.

One mnemonic whose host population accumulates many members through both homogenesis and heterogenesis is the belief that "It is best not to go to church on Sunday". Many of its hosts received it (homogenically) from parents or friends who already had the idea. This makes their mnemons homoderivative.

However, many people got the idea because as children their parents made them go to church every Sunday, even when they did not feel like going. The resulting aversive experiences often lead the children to conclude that it is best not to go to church on Sunday. Ironically, their belief results from their parents' strict adherence to exactly the opposite belief. The pro-churchgoing mnemon influences some parents to generate something radically different in some of their children. So those parents' mnemon is heterogenic while the children's mnemon is heteroderivative. Any parent who raises some children to be church going and some to be church avoiding has a churchgoing mnemon that is both homogenic and heterogenic.

The concepts of replicator evolution and epidemiology directly pertain only to the homoderivative sector of a mnemon's host population. In this sector, we can properly refer to mnemons as the "units of imitation" discussed by Dawkins. This allows a very restricted denotation in which a meme is *defined* as a *homoderivative mnemon*. The definition of a particular meme contains an abstract sameness criterion like the ones defining mnemons, but also includes a criterion of causality, namely, that it is homoderivative. So each meme has a corresponding mnemon: the memory abstraction defined without reference to homoderivative causation.

Although the church-avoiding mnemon does not occur primarily as a meme, one can still understand its proliferation in terms of memes. Simply divide the hosts into two groups: hosts of the church avoiding meme and dropouts of the church going meme (meme and meme-derived mnemon hosts). The first group can be studied directly as meme hosts. The second group's growth rate can be studied as a function of the church-going meme frequency. So the study of meme proliferation can be valuable to understanding the growth or decline of both of these constituent groups, whose combined numbers include nearly all the church-avoiding host population.

Some mnemons are neither memes nor meme-derived in most of their instances. For these mnemons, the study of meme proliferation is of little use. Consider what happens when an earthquake of harmless but noticeable intensity strikes Los Angeles. Millions of people suddenly have the idea that an earthquake has struck on that particular day. So at first the host population does not result primarily from mnemon copying. In fact, the people who directly experience the quake may remain a majority of the idea's hosts, especially if the quake is too mild to get much news coverage. Replicator theory has extremely limited relevance in studying this kind of host population growth. The theory best applies to the limited but still vast realm of memes and meme-derived mnemons, i.e., the realm of memetics.

The ability to unambiguously identify mnemons as homoderivative now becomes crucial to memetic theory. For instance, when someone receives the hell mnemon from one person and the imminent doomsday mnemon from another, is the resulting $A*B$ combination homoderivative or heteroderivative? The $A*B$ host has copied both mnemons from pre-existing hosts. But the event that actually forms $A*B$, namely $\sim A*B + A*\sim B \sim A*B + A*B$, does not actually contain $A*B$ as an input mnemon. The mnemon appears not to be distinctly homoderivative or heteroderivative, a problem in deciding how to proceed.

The problem can be resolved by recalling that mnemons propagate only with respect to an abstraction. Although the A^*B host is homoderivative with respect to abstraction A , and homoderivative with respect to abstraction B , the instance of A^*B is clearly heteroderivative with respect to abstraction A^*B . So A^*B formed by the event $\sim A^*B + A^*\sim B \sim A^*B + A^*B$ is not a meme, although it is meme-derived.

Yet as mentioned earlier, A^*B can also propagate as a set by the non-parental conversion event $A^*B + \sim A^*\sim B \rightarrow 2A^*B$. Formed this way, A^*B is a meme. Thus, the host population of A^*B is yet another mixture of memes and meme-derived mnemons.

Disingenuous propagation raises similar questions. Consider the following mnemons:

Mnemon P is the *belief* that "bee pollen invigorates".

Mnemon Q is *awareness* of the "bee pollen invigorates" proposition.

Mnemon R is the belief that "it is profitable for bee pollen merchants to tell customers that bee pollen invigorates".

If a merchant holds the $\sim P^*Q^*R$ combination, then a disingenuous propagation event might then be represented as

$$\sim P^*Q^*R + \sim P^*\sim Q^*\sim R \rightarrow \sim P^*Q^*R + \sim P^*Q^*R \sim P^*Q^*R + P^*Q^*R.$$

This event clearly involves replication with respect to the awareness meme Q , and the profitability meme R . Yet this event alone is not homogenic with respect to P , because the merchant is a non-host of P . Still, there is a mechanism of indirect replication in this case. If the P^*Q^*R host goes on to pay the merchant, it helps preserve the meme R in the merchant and also pays helps pay the bills that the merchant needs paid in order to continue instilling P^*Q in new hosts. This form of recursion is already recognized in such fields as marketing science and consumer education, and hence is not a distinctly memetic insight. Also, the actual profitability of transmitting P^*Q involves numerous business and marketing science considerations, such as how many people are persuadable, how much they are willing to spend, how much the bee pollen costs to produce and distribute, etc. Understanding the disingenuous spread of P^*Q^*R is largely covered by older disciplines, so the propagation event here serves mainly to illustrate how it is diagrammed and in what sense it can involve replication of P . Note that the event $\sim P^*Q^*R + \sim P^*\sim Q^*\sim R \rightarrow \sim P^*Q^*R$ may also happen recursively when bee pollen is incorporated into multi-level marketing schemes.

Simple non-commercial lies also qualify as events in which the transmitting party holds an awareness of a proposition but not the belief in that proposition. If the lie is believed by the recipient, it would take the form $\sim S^*T + \sim S^*\sim T \rightarrow \sim S^*T + \sim S^*T \sim S^*T + S^*T$, where S is the belief in a given statement and T is mere awareness of it as a proposition. There may be reasons for the $\sim S^*T$ host to repeat the lie many times to many people, and of course the new S^*T hosts may have reasons for honest retransmission as well (by events such as $S^*T + \sim S^*\sim T \rightarrow S^*T$).

10 Meme, Concisely Defined

Defining the word meme concisely but technically without reference to the other neologisms, we have:

MEME

A memory item, or portion of an organism's neurally-stored information, identified using the abstraction system of the observer, whose instantiation depended critically on causation by prior instantiation of the same memory item in one or more other organisms' nervous systems. ("Sameness" of memory items is determined with respect to the above-mentioned abstraction system of the observer.)

The causation of a new instantiation can happen by a great many routes. The role a meme plays in causing a new instantiation can seem rather passive, as when parents spend days trying to decide which meme they will use for naming a newborn. Or the meme can play a strong role in manipulating host's communication behaviors toward retransmission, as when the idea of astrological compatibility motivates believers to retransmit to all potential mates. The latter kind of meme qualifies for the more restrictive term *thought contagion*.

Although my meme definition refines Dawkins's original informal definition, it still covers a vast range of phenomena. There are, however, those who want the term "meme" to refer to all sorts of cultural phenomena that might be regarded as replicators. Yet this can lead to great confusion, especially over how to measure the extent of propagation.

Still, one can study either a chain letter (non-meme) or the thought propagated by the chain letter (a meme) as replicators. Artifacts and numerous other cultural phenomena might be investigated as instantiations of informational replicators, yet they are not memes by the above definition⁵. The above definition does not have memes "residing" in anything but an organism's nervous system, though it might be generalized to include artificial minds.

Yet clothing zippers, co-dependencies, chain letters, groups, behaviors, institutions, entire societies, and numerous other social or cultural phenomena have been discussed using various kinds of replicator and vehicle models. The strength of the replicator concept varies across such a wide range of phenomena. Yet Pocklington and Best [1, 14], for instance, have published good evidence of culturally replicating information in the medium of usenet postings. They quantify instantiation in terms of distinct postings rather than copies downloaded, messages read by people, or mnemons retained by people. The distinctions between postings and human hosts matter, especially because people on the usenet often create new copies of material with which they *disagree* by clicking the "post reply" button in their Internet software. Usenet postings would qualify as *meme relics*, or from Dawkins [4] *meme phenotypes*, or even *text contagions*, but not *memes* under the above definition. They are valuable indirect evidence of memetic replicators, much as sea shells washed ashore are valuable evidence of reproducing organisms in the water.

When viewed as replicators, most artifacts involve brains at some point in the causal pathway to forming new "copies". A computer virus, however, can be seen as an artifactual replicator that

usually spreads from machine to machine (or disk to disk, etc.) without being hosted by a new brain for every replication. The instantiations of the computer virus are not memes, but the algorithm of the virus can be a meme: the prankster who initially wrote the code may find his code being learned and copied by other pranksters. We thus have artifactual and brain-stored replicators.

Similarly, one can investigate the role an enzyme plays in causing new instantiations of "the same" enzyme in one or many cells. The investigation will, of course, always find that nucleic acids play a crucial ("central") role in causing new "copies" of the enzyme—a fact that makes it not scientifically *necessary* to treat ordinary enzymes as replicators. But the enzyme can still be viewed as a very indirect, multistage replicator. Cytochrome C, for instance, helps produce ATP that in turn helps produce new "copies" of cytochrome C. Yet much as one does not say that a protein enzyme is or contains a "gene", so too do I not say that an artifact is or contains a "meme". Still, an artifact can function as a medium of communicating knowledge of how to make new copies of "the same" artifact, and this difference from the role of proteins in biology suggests that there should not be a "central dogma" in memetics. It is a situation that Dawkins [4] notes in his remark that "there may be 'Lamarckian' causal arrows leading from phenotype to replicator"⁶.

A more general term than *meme* might nevertheless help clarify these distinctions and provide a way of discussing other kinds of cultural replicators. Noting that biologists took the word *code* and invented *codon*, we can take the word *replicate* and coin the word *replicon*. The adjectival form is then *repliconic*. The associated discipline name would be *repliconics*. Its central theory would be the generalized evolutionary replicator theory or just generalized replicator theory. The subfield dealing with culture would be *cultural repliconics*. Text contagion theory, computer virology, and memetics would be some of the sub-subfields.

The various preliminary distinctions that go into defining the "meme" may appear to be another example of how memetics departs from analogy to genetics. Yet chemistry also has many distinctions that place nucleic acids in a very small subclass. Molecules can be catalysts or not. They can also be autocatalysts or heterocatalysts. The early oceans may have contained oligonucleotides formed by polymerization of smaller components. Some would have formed by non-autocatalytic polymerization, even in outer space. But if any did behave autocatalytically, they would have proliferated into predominance. They would have been a subclass of molecules generally, much as memes are a special subclass of memory items. The "new replicators" that Dawkins introduced are in an environment with similar non-replicators, much as the earliest biomolecules were.

11 Stemming the Tide of Expanded Definitions

Because Dawkins never offered an explicitly formal definition of the word *meme*, a great many writers have taken the liberty of expanding its meaning to include nearly any social or informational phenomena they wished to see treated with seemingly the same clarity and precision found in a molecular genetics lab. Taking this to extremes, some have said that since "the meme" is just propagating information without regard to medium, that even genes are just a special case of memes. One writer even posted to the Internet that memetics was the science of

information in all sectors of the universe. Another sees "proto-memes" in the infinitesimally early stages of the Big Bang. There are even writers who insist that memes can be instantiated only in artifacts, never in brains. The problem is that if the word *meme* means just about whatever a writer wants it to mean, then it means practically nothing at all. The resulting bedlam has led some critics to issue blanket indictments against all of memetics, insisting that memeticists have not clearly defined their subject matter. These are generally people who have not yet read a formal and more restrictive definition.

Still, some expansions of Dawkins's original usage need to be addressed carefully. Among these is the expansion offered by Dennett, in which a "meme" can be instantiated by a wide range of "meme vehicles" other than brain-based or artificial minds. Thus, a "meme" for spoked wagon wheels is instantiated not only in the brain of the carpenter building it, but also in the finished wheel itself. The wheel does, after all, contain information that a new carpenter can use to copy the wheel. This departs from Dawkins's usage, in which the meme resides only inside the brain and an artifact such as a wheel would presumably be part of its extended phenotype.

Dennett does, however, correctly recognize the wheel as an artifactual medium of communication. This can seem synonymous with the phrase "vehicle of communication", a connection that tempts us to consider the wheel as a meme vehicle and a locus of meme instantiation. Dennett recognizes moreover that communication by artifact is not always intended, as when the enemies of those traveling by spoked wheel copied the visible and mobile artifact for their own benefit. The actual communication event generally involves more than just a stray wheel resting in a field, but includes a human being demonstrating its usefulness by riding around with two or more wheels, an axle, a horse, and the rest of the wagon.

Expanding the term "meme" in Dennett's manner has a further appeal, in that it seems to offer a continuous chain of material substrates from one instantiation to the next. Yet when a carpenter builds a wheel from memory, there is actually no instantiating medium in between the brain and the finished wheel. So any worry about instantiation gaps applies for both definitions. That worry is unfounded anyway, because an instantiation gap does not imply any gap in physical causation. An instantiation gap exists between one autocatalyst molecule and the next, too, as various intermediates are formed and the initial molecule always has at least a tiny physical separation from the new copy. Likewise for a spreading computer virus, where the cable connecting one computer to the next is often too short (and transfer rate too slow) to contain an entire copy of the viral software: a long physical gap may exist between one instantiation of the virus and the next. Yet Dennett's examples show that useful insights are gained by treating artifactual information as replicators, and it is for just such cases that I offer the term *cultural repliconics*.

A more serious problem with allowing for all sorts of "meme vehicles" as meme instantiation loci is that it tends to confuse the measurement of propagation. Even when the "vehicles" are discrete, there are questions of whether they should all be enumerated equally. Copies of an old advertising logo may still exist in landfills a century after the product disappeared. The fact that the human host population of a meme is zero certainly tempts us to call the meme extinct, even if it can be brought back from extinction by an inter-century communication event to some future excavator. And if supernova radiation from a few light-years away leaves an earth full of unused

artifacts until the Sun's demise, we would tend to say that the memes went extinct with the end of humanity rather than with the end of the planet.

The problems of enumerating the instantiations become even murkier with non-discrete "meme vehicles". How many copies of the distress signal from the Titanic now exist at a radius of 86 light-years? What about a still local message crammed into a 300 kilometer thick (1 millisecond) burst of microwaves from a satellite? In such cases we tend not to enumerate the theoretically feasible number of receptions of the message as "memes", but instead only those which actually *are* decoded and stored in minds.

The consideration of replicating cultural phenomena not instantiated by any single mind has led to interesting and worthwhile insights. Yet sayings such as "a scholar is just a library's way of making another library"⁷ bring on questions of whether even Dennett is trying to pack too many possible meanings into the one word "meme". Scientists reading these statements often get the impression that while "cute", it is not specific enough to be part of a real science. Not surprisingly, Dennett himself, after venturing down this road filled with every variety of "meme vehicle", ends up questioning whether there can be a science of memetics at all and answering in a doubtful voice⁸. The challenges of developing a unified replicator theory for so many kinds of vehicles are perhaps big enough to become terrifying. Better, in my view, to consider the scientific merits of a more restrictively defined "memetics" and take up the question of other classes of cultural replicators separately.

The substrate-specific definition of "meme" stands in some contrast to the apparent substrate neutrality of the term "software". Yet this is actually a result of the many kinds of artifacts that serve as computer "memory". The term "software" does not really refer to information in *any* medium. Suppose a robot using Cartesian coordinates builds a screw. A different model of robot using polar coordinates analyzes the screw and builds copies using completely different measuring units, and digitizing in finer detail. We do not say that the screw contains the "software" for making screws, or any kind of "data" or "software", even though it does contain replicating information. So the word "software" is actually medium-specific, but only with respect to an ever-expanding *class* of information media. The screw can, however, be viewed as a *software relic* much as the spoked wheel can be viewed as a meme relic. Both can also be viewed as instantiations of generalized (non-meme) information replicators. In this latter perspective, a robot is the screw's way of making another screw and a carpenter is the wheel's way of making a new wheel. It is a repliconic perspective that has some of the flavor of memetics even though memes as I define them are not the direct topic of discussion.

In biology, the term "gene" has progressed toward more specific and technical definitions. Scientists have not attempted to expand its meaning to include the information stored in all sorts of vehicles, even though many types of vehicles contain biological information. Even other replicating entities such as prions are not considered to be or contain instantiations of genes. And we certainly do not see anyone attempting to expand the term "gene" to include information in all sectors of the universe. In order to be taken seriously in science, the term "meme" needs to be refined toward greater, not lesser, specificity than its original usage. The definition I offer is more formal and specific than what Dawkins presented in 1976 [3], yet it still covers the vast territory that he intended.

12 Meme Sizes

Some efforts have been made to incorporate the idea of "size" into the definition of the word *meme*. This includes those who favor the "smallest" possible units, as well as those who favor the "largest" possible units. Unlike those who expand the definition of *meme*, these scientists are indeed looking for ways to render the meaning more specific. Yet not all attempts at specificity are equally useful in the study of real phenomena.

Size is a fairly easy thing to measure for segments of DNA or their corresponding proteins, as well as for pieces of text. However, the concept of "size" becomes troublesome with beliefs and other information stored in the brain: general methods of "size" measurement are not currently available, and even if they were, they might register different "sizes" for "the same" belief in different brains. The most we can really say is that a set of memes is, in general, a partially ordered set (as defined in set theory). One rather arbitrary system of partial ordering is based on the size of conjunctions of the mnemons identified by a particular abstraction system. Take the mnemons expressed by the following 3 statements, for instance:

Mnemon A: "There is only one true God".
Mnemon B: "Christ is Lord".
Mnemon C: "Unbelievers are damned".
Mnemon D: "Earthly life is better among believers".

We have no basis for saying if $A > B$, $A < C$, etc.

We can say $A * B > A$, and $A * B > B$.

But you cannot say $A * B > C$ or $A * B < B * C$, etc.

We can, however, say $A * B * C > A * B$, $A * B * C > A * C$, etc.

In other words, if the hypothetical faith only says "There is only one true God", and "Christ is Lord", we cannot, for instance, say that it is "bigger" (has more "size") than the faith that only says "Christ is Lord" and "Unbelievers are damned". Nor can we compare the "sizes" of these component beliefs. Moreover, completely unordered sets such as $S = \{A * B * C, A * B * D, A * C * D, B * C * D\}$ demonstrate clearly that size cannot be a universal criterion in defining which mnemons are memes.

Mnemon size can, however, become an empirical consideration when studying the special case of a fully ordered set of mnemons, such as $S' = \{A, A * B, A * B * C, A * B * C * D\}$. We might find that element A does not induce much replication. Then we might find that $A * B$ induces more replication, but that $A * B * C$ induces still more. Yet we may also find that $A * B * C * D$ achieves less replication, perhaps by requiring too much information transfer to happen reliably. One can still decide based on this to choose $A * B * C$ as the main subject of investigation without requiring size to be a criterion in the definition of all memes. Since A may have propagated long before the first occurrence of $A * B$, and $A * B$ long before $A * B * C$, it is important to be able to consider all the elements of set S' as memes.

13 Massively Cooperative Propagation

Though religious meme sets such as those above spread by inducing a wide variety of one-to-one transmission events, some can also induce events involving large numbers of participants. In multistage events, there can also be large numbers of participants in some stages and few in others. Thus, (retaining the symbol meanings of the preceding paragraph) an individual might spread $A*B*C$ through the event $A*B*C*D+\sim A*\sim B*\sim C*\sim D$ $A*B*C*D+A*B*C*\sim D$. But then it may take the 1000 other believers in a community to achieve the next event:

$$1000A*B*C*D+A*B*C*\sim D1001A*B*C*D.$$

Now consider what happens when adding a few more memes:

Meme E: "Love your neighbor as yourself"

Meme F: "The Spirit lives in the community of believers"

Meme G: "Church X is God's Church".

As I noted in *Thought Contagion* [12], memes which cause greater cooperation among their own hosts can thereby achieve propagation advantages by raising prosperity and suppressing the sort of personal conflicts that may lead to dropouts. The "love your neighbor" meme *E* even motivates more one-on-one evangelism in some settings while promoting collective meme propagation in other settings. The meme expands the range of unbelievers that adherents wish to save from damnation: instead of just wanting to "save" a few friends and relatives, they want to "save" even strangers. Yet the meme also works in many ways to improve *community* life among believers, an effect I discussed in *Thought Contagion* [12] and Stark documents for early Christians in *The Rise of Christianity* [16]. So when an individual Christian attempts to spread memes *A* through *G* to a pagan, the pagan may well remain unconvinced. Yet the pagan realizes that meme *D* is testable merely by spending some time among believers, and without waiting for an afterlife. In ancient times, they would have found a Christian community thriving from cooperation, and taking better care of each other's misfortunes than did the pagans. That would have impressed them that at least the meme *D* part of the Christian message was true. This in turn would have made it cognitively easier to believe the "Spirit" meme *F*, and the "Spirit" meme *F* would make it easier to believe the "God's Church" meme *G*. Finally, that would make it easier to believe other Christian memes such as memes *A*, *B*, and *C*.

In addition to these cooperative conversion effects, a community can also achieve greater rates of preventing the dropout event $A*B*C*D*E*F*G\sim(A*B*C*D*E*F*G)$ and the mortality event $A*B*C*D*E*F*G0(A*B*C*D*E*F*G)$. The community role in dropout prevention would result in part from conformity pressure, and in part providing social, emotional, material, and health care benefits. It would augment such dropout prevention effects as the threat of hellfire discussed by Dawkins [3], and the efforts of individuals to shore up the faith of anyone expressing renewed doubts. The mortality prevention effect, resulting from such things as the community feeding the poor and nursing the sick, is documented by Rodney Stark in *The Rise of Christianity* [16].

For some memes, the effect on rates of cooperative propagation is particularly striking. With Hutterites (denoted here with meme symbol H), for instance, we observe many events of the form $2H \rightarrow 2H + \sim H$ (Two Hutterites have a baby non-Hutterite), followed by an event such as $20H + \sim H \rightarrow 21H$ (Twenty Hutterite adults impart the faith to the child). Then we see events such as $165H \rightarrow 83H + 82H$ (One Hutterite colony of 165 splits into two colonies of 83 and 82)⁹. Crucial to setting the rate of this event, however, are the family structure memes that raise childbirth rates to 10 per couple while keeping the (permanent) parent to child inculcation rate above 90 percent. A distinctly Hutterite meme distributing the chores and costs of child-raising among the whole colony's adults probably plays a strong role here, as it dilutes the usual pragmatic motives for regulating fertility. The idea of splitting the colony when it grows to a certain size range keeps colonies always in a phase where they need a constant source of new young hands to build and run the collectives. Since they do not recruit outsiders, it effectively augments the pressure to keep having the numerous children.

The phenomenon of large numbers of humans propagating a movement by acting in concert has been cited as evidence for the group selection of human genes. Wilson and Sober [17], for instance, take the colony behavior of Hutterites as evidence of innate hive-like social dispositions arising from group-selected genes. Yet the ideological imperatives discussed above can explain the evolution of a Hutterite meme set in terms of memetic selection alone — without requiring any new innate factors beyond a very general capacity to learn and comply with cultural mores¹⁰. Likewise, the Christian propagation advantages that arise through community behavior do not suggest a special genetic mechanism. As important as they are, massively cooperative meme replication events remain a subclass of memetic events in general. The fact that they happen for a variety of memes in various populations suggests that communities can achieve certain meme transmission effects beyond the capacities of single individuals. Yet it does not of itself show that the memes must be relying on an innate imperative for highly collective action.

14 Centralized Communication

Centralized meme transmission stands in contrast to massively cooperative propagation. Here, a very few people act to spread a meme to vast numbers by events such as $A + 1000000 \sim A \rightarrow 10001A + 990000 \sim A$. (Host of A communicates to 1000000 non-hosts of A , yielding 10000 new hosts of A plus 990000 continued non-hosts of A .)

Mass media often play an important role in such replication events. When they do, most of the recipients cannot go on to play the role of meme retransmitter by the same kind of centralized event. This may at times make centralized communication less suitable for study with *recursive* replicator theory. It can also at times limit the role of distributed replication: much as humans can acquire legionella bacteria centrally from central air conditioning systems, so too can we acquire memes by way of intentionally central meme spreading systems.

Another feature of centralized communication is that not all of the people transmitting the message are actually hosts of the meme. The idea that "Coke is the real thing", for instance, has probably been broadcast by many celebrities who prefer to drink something entirely different in the privacy of their homes. This again limits the usefulness of the recursion principle, as sender and receiver do not always have "the same" meme. The sender, for instance, may only have the

idea that it is *profitable to say* "Coke is the real thing" rather than actually *believing* in the message. Yet as with non-centralized profitable communications, people who adopt the meme often spend money that pays merchants and advertisers to send the message again and again. This is a phenomenon recognized and applied long before the advent of memetics, and already studied in marketing science.

Mature recipients of centralized messages often understand that the sender may not believe what she says, thus limiting receptivity to the message. Communications from friends and family generally do not have an apparent profit motive, too, and can thus enjoy a more privileged reception. Desires to maintain harmonious relationships also cause people to pay closer attention to messages from direct acquaintances. This helps maintain the importance of non-centralized communications from immediate family and acquaintances in the age of mass media. In turn, it prevents all of memetics from being reducible to existing work in media studies or marketing science.

The continued importance of distributed communications even manifests itself in the recursive propagation of memes specifying which centralized sources to consume. The Bible, for instance, may look like a centralized communication, coming from mass production plants ever since moveable type was invented. But the idea of buying and reading it propagates person to person in the population, along with various memes specifying what passages to emphasize and what they mean. Another example that I discussed in *Thought Contagion* [12] was the localized propagation memes for listening to centralized political talk-radio shows. Listeners to shows with pro-business, anti-tax messages play the radio openly in the workplace, allowing co-workers to learn about the show and its message. But listeners to shows that might politically offend the management feel inclined to use headphones, which blocks the local retransmission of their political and show-preference memes. Even that most centralized of modern media, television, exhibits natural selection processes, as when the remote control caused a trend toward greater violence, sex, and melodrama — the types of content that happen to stop the passing "channel surfer"¹¹. Far from replacing distributed memetic evolution, the centralized media have instead opened up new realms for recursive propagation and natural selection in competing meme bundles.

15 The Fundamental Role of Abstraction in Science

The great potential for confusion in discussing cultural phenomena forces explicit reference to systems of abstraction. Yet the axiom of abstraction, fundamental to all of science, is generally invoked on a tacit level in most disciplines. Indeed, the axiom of abstraction is also known as the axiom of comprehension. It merely states that for any attribute, one can define a set of all the entities that have that attribute. Saying that two entities are "the same", then, is tacit shorthand for saying that they are elements of the same set, whose inclusion criterion is the attribute. The phrase "the same with respect to an abstraction" serves to remind readers of the underlying mental operations involved in calling any two entities "the same".

In the physical sciences, abstraction manifests itself every time someone refers to an entity as having the attribute of being a "water molecule". "Water molecule", is an abstraction which scientists have found useful for discussing phenomena. What they really mean by "water

molecule" is a particular *pattern* of matter and energy. It is a way of calling two or more patterns of matter and energy "the same", ignoring such differences as location, velocity, rotational states, vibrational states, oxygen 18, Hydrogen 2, nuclear spin states, electron spin states, electron excitation states, quark states, etc.

Is it ever legitimate to identify *patterns* amid all this seething matter and energy? A philosophy of science question. Yet the grouping of vast categories of objects into sets defined by attributes seems to be a fundamental feature of human thought. Without formally justifying the practice, one can note that this can be an efficient way of storing vast amounts of knowledge in a finite brain. One can also theorize that evolution has favored brains that do this because it provides sufficiently functional representations of reality to give an animal a survival and reproductive advantage. But these arguments themselves depend on abstractions.

Regardless of why we rely so much on abstractions, science as we know it is largely a project to develop and test ever stronger systems of abstractions with which to describe and comprehend reality. The "stronger" systems of abstractions are defined as those which explain more of reality with reliance on fewer essential abstractions. Yet deep questions remain on whether nature will someday indulge the physicist's quest for the kinds of "ultimate" abstractions of "grand unification theories". Will our desire for ever more unifying abstractions instead be frustrated by some fundamental complexities of a reality not designed specifically to please the human mind? This we have yet to learn.

Despite advances in fundamental knowledge, we cannot run through the equations of quantum mechanics to explain something as complicated as a cell or a DNA molecule. So we invoke further layers of abstractions for these vastly complicated systems. Instead of representing "adenosine" in terms of a chemical formula, a single letter is used. And "little things" like the dissociation of H⁺ from phosphate groups and particular serpentine shape traced out by the molecule are ignored. Compared to the level of elementary particles, molecular biologists focus on patterns of patterns of patterns, layers of abstraction removed from what physicists call "fundamental".

A great deal of science went into demonstrating that "genetic material" is a useful abstraction, and that "nucleic acid" can be used as an equivalent abstraction here on Earth. Likewise for the discovery that "nucleotides" are useful abstractions for describing nucleic acids. Yet the pre-molecular concept of "gene" was a useful abstraction, and its very utility provided impetus to the research that led to more powerful molecular abstractions. More recent arguments over different molecular definitions of "the gene" amount to arguments about which abstractions are stronger. Yet the "the gene" started as an abstraction based on studies of entire organisms, and has progressed into an abstraction based on studies of molecules.

Materials can also be *manipulated* to fit a set of desired abstractions, as has been done with digital electronics. One voltage interval is chosen to represent the abstraction "1", and another the abstraction "0", with all sorts of "low level noise" to be ignored. Analog vacuum tubes, transistors, and other devices are then wired to produce abstractly bimodal outputs corresponding to abstract operations on abstractly bimodal inputs. Hence the "NOR gate", for instance. Still higher levels of abstraction arise when referring to "software", where specific voltages and even

patterns of "1's" and "0's" can be ignored in deciding whether two "programs" are "the same". Science again builds layers of abstractions, this time working from the low level up rather than the high level down.

Because "replication" depends on "sameness", and the "sameness" of any two "water molecules", "DNA molecules", etc. exists only with respect to an abstraction, it follows that replication only happens with respect to an abstraction. Abstraction systems and sameness criteria are important in all evolutionary replicator theories. Yet "replication" also involves the notion of causation. Specifically, the word "replicator", can be replaced with the cumbersome phrase "instantiation of an abstraction that causes a new instantiation of the same abstraction". This is the tacit meaning in use for all kinds of evolutionary replicator theories ranging from the "artificial life" to memes to autocatalytic molecules that might evolve in the oceans of Europa.

Memes are abstractions currently based on macroscopic observation. Whether it will stay at this level remains to be seen. There is, however, a school of thought that seems to insist that memes must be "detected" by some kind of molecular or microscopic means in order to be valid abstractions. Yet the same people may routinely treat "Nazism" or "monotheism" as "real" phenomena without providing any molecular or cellular basis. Many even go on to attempt to get others to hold "the same" idea as theirs about memetics. In doing so, they unwittingly affirm the underlying premise of memetics, that one person can cause another person to have "the same" idea by way of "communication". They need only admit further that different ideas can spread recursively at different rates before seeing the evolutionary arguments of memetics follow mathematically. There too, many of them affirm a principle of memetics by avidly trying to make their own beliefs spread at a greater rate than competing beliefs. This is not the same thing as accepting specific memetic hypotheses, but it does show tacit acceptance for the underlying tenets of memetics.

Nevertheless, some of the discomfort that many voice over memetics arises almost subconsciously from the fact that science has not discovered an absolute, fundamental, or privileged system of abstractions with which to discuss socially transmitted information. To worsen the situation, some popular writers seem convinced that they have actually discovered a set of fundamental "units" of mass culture, that is, a strongly preferred or "privileged" system of abstractions resembling the nucleotides and genes of biology. But the "sameness" of any two people's learned information about a topic depends on the abstraction system of the observer. With genes, nature has rendered a few very similar abstraction systems far more powerful than the alternatives, so that scientists do not notice the role of the observer's abstraction systems. But there are many ways to define "anti-abortionism", for instance which is another way of saying that the abstraction system and survey questions can be constructed in many different ways. In reality, memeticists will probably have to abandon the "fundamental unit" idea much as physicists have now abandoned the idea of an absolute coordinate system (framework of location and time abstractions) for the universe. Not only are meters and seconds arbitrary units of measure, but measurement results depend on the framework in which measurement is taken. More fundamentally, just as physicists now accept that the "simultaneity of events" exists only with respect to an observer's coordinate system, so too must memeticists accept that the "sameness of ideas" exists only with respect to an observer's abstraction system. While this is not a "special theory of cultural relativity", it does show scientific precedent for admitting that

multiple systems of abstraction can apply to a given class of phenomena. It does not mean that all abstraction systems are equally useful, but it does suggest that science can proceed without the assumption that there must be one abstraction system that is universally right for memetics.

16 Population Memetics

Evolution is fundamentally a quantitative as well as a qualitative theory. The abstractions that allow us to discuss memes and memetic events set the stage for discussing quantitative *event rates*. Differences between memes in the rates of replication and termination events are what give rise to the natural selection of memes. They are hence essential to the evolution by natural selection in memes. From the fact that event rate parameters differ between memes, it follows *mathematically* that natural selection must happen. Yet this statement can be rendered much more specific. The mathematically *necessary* consequences of differing event rate parameters can be *characterized*, using systems of differential equations for meme host population versus time. Defining the units and quantifying the events thus allows us to analyze the host population *dynamics* of memetic evolution.

The particular terms needed for a system of equations to model the population dynamics of a specific set of memes will depend upon what kinds of events occur at non-negligible rates for the memes being modeled. A vast range of event forms can be conceived, but the rarest of them do not need to be modeled in order to gain acceptable accuracy — much as the rarest side reactions in a chemical process can be ignored in quantitative chemistry. Models will in general have to account for at least two population groups, namely, those for hosts and non-hosts of a meme. Accounting for additional population groups is accomplished by expansion to a system of more than two equations. Most models will also have account for some very common types of memetic events, such as simple parent to child transmission, non-offspring conversion, spontaneous dropout, and mortality. Two-equation systems to model these basic kinds of events therefore constitute a starting point for mathematical memetics, allowing further elaborations to be added as required.

The following two differential equations pertain to two memes whose host populations are represented by $N_1(a,t)$ or $N_2(a,t)$ — population age profiles. All members of the total population $N(t)$ are assumed to be counted somewhere in either $N_1(a,t)$ or $N_2(a,t)$, indicating that the two memes are complements of each other. (In actual practice, one would often want to divide the population into more subgroups, such as the host populations of an idea, its opposite, and hosts of neither. Some subgroups might correspond non-replicated mnemons rather than memes. The present discussion is limited to two groups in order to illustrate quantitative methods as simply as possible.)

The other parameters in the equations have the following meanings: t is time in years, a is host age, p is the age of a second person — the idea propagator — used in places where two people's ages are involved.

$R_1(a)$ is the fertility rate for meme-1, in children per host of age a per year — the quantity parental parameter. $K_{11}(p,a)$ is the fraction per year of children of age a who learn meme-1 from an age p parent who hosts meme-1 — the efficiency parental rate. $K_{21}(p,a)$ is the fraction per year of

children of age a who learn meme-1 from an age p parent who hosts meme-2, a kind of parental "failure rate" for meme-2. Again, for the sake of "simplicity", the different R and K values that may occur when one's parents come from different host populations are not modeled here. (More than just R and K parameters are involved, since the occurrence rates of "mixed" versus "unmixed" couples change with changing host populations.)

${}_{12}(p,a)$ is the average annual net number of non-parental converts a meme-1 host of age p makes per unit meme-2 host population-age density at age a in his society. ${}_{12}(p,a)$ is the average annual net number of non-parental converts a meme-1 host of age p makes per *percentage-year* of meme-2 hosts of age a in his/her society. Non-parental conversion rates represented by ${}_{12}(p,a)$ are sensitive to how crowded the society is as a whole while ${}_{12}(p,a)$ rates per meme-1 host are purely sensitive to the *fraction* of meme-2 hosts in the society. The latter reflects the non-parental conversion between, for instance, spouses: people do not generally double the number of spouses as the population doubles. Yet the number of people one encounters on the street might well double as the population doubles. If so, then non-parental conversations on street corners would be modeled using ${}_{12}(p,a)$.

γ_1 is the fraction per year of meme-1 hosts who convert to meme-2 without any prior meme-2 hosts teaching them, or who at least convert by mechanisms that do not depend on the size of the meme-2 host population¹². Preventing such "dropouts" is one form of preservational advantage (information longevity advantage) for meme-1. Finally, $M_1(a)$ is the rate of mortality per age a meme-1 host per year.

Swapping "2" subscripts for "1" subscripts in the above sentences gives the parameter definitions corresponding to changes in meme-2 prevalence¹³.

$$\begin{aligned}
 \frac{dN_1(a,t)}{dt} = & \int_a^{\infty} R_1(p-a)K_{11}(p,a)N_1(p,t)dp \\
 & + \int_a^{\infty} R_2(p-a)K_{21}(p,a)N_2(p,t)dp \\
 & + \int_0^{\infty} \gamma_{12}(p,a)N_1(p,t)N_2(a,t)dp \\
 & + \int_0^{\infty} \frac{\beta_{12}(p,a)N_1(p,t)N_2(a,t)}{N(t)} dp \\
 & - \alpha_1 N_1(a,t) + \alpha_2 N_2(a,t) \\
 & + \frac{\partial}{\partial a} N_1(a,t) - M_1(a)N_1(a,t)
 \end{aligned}
 \tag{1}$$

$$\begin{aligned}
\frac{dN_2(a,t)}{dt} = & \int_a^\infty R_2(p-a)K_{22}(p,a)N_2(p,t)dp \\
& + \int_a^\infty R_1(p-a)K_{12}(p,a)N_1(p,t)dp \\
& + \int_0^a \gamma_{21}(p,a)N_2(p,t)N_1(a,t)dp \\
& + \int_0^a \frac{\beta_{21}(p,a)N_2(p,t)N_1(a,t)}{N(t)} dp \\
& - \alpha_2 N_2(a,t) + \alpha_1 N_1(a,t) \\
& + \frac{\partial}{\partial a} N_2(a,t) - M_2(a)N_2(a,t)
\end{aligned}
\tag{2}$$

The first two terms in equation 1 are the parental terms. In the first term, the group of $N_1(p,t)$ parents of age p is multiplied by the average number $R_1(p-a)$ of children per adult that they had a years ago to get the number of children of age a having parents of age p . This then is multiplied by $K_{11}(p,a)$, the fraction per year of children in this latter group having meme-1 passed down to them (while they are of age a and the teaching parent is of age p). This is then integrated over the entire range of parents' ages ($p=a$ to $p=\infty$) to get the total rate at which meme-1 hosts are passing the meme down to children of age a . The second term gives the rate at which the meme-2 host population parentally produces meme-1 hosts of age a .

In practice, there may be many cases where a useful mathematical model can be attained by treating the parent to child meme transmission as if it all happened when the children reached the single age c_1 , the *average* age at which they pick up meme-1 from a parent. Also, one might find that the transmission rate per child depends very little on parent age differences within the mainstream host child raising years. If this is true, then one can replace the $K_{11}(p,a)$ function with the very simple function $k_{11} \delta(a-c_1)$, where δ denotes the delta function, and k_{11} is simply the overall fraction of children who acquire meme-1 from their parents a much easier thing to measure than transmission versus age. The remaining functions in the parental terms are just fertility versus age and the population age profile the sort of data that demographers and census-takers have already measured for some groups.

The next two terms in the equation concern the non-parental conversion mode of transmission. The first of these is the one that is sensitive to the total number of potential converts, $N_2(a,t)$, rather than merely their proportion to the total population. If both $N_1(a,t)$ and $N_2(a,t)$ doubled, each individual meme-1 host would be winning twice as many converts and the meme-1 host population (at double size) would be winning four times as many converts per year. On the other

hand, the second term on line two would only double, and not quadruple, if each group doubled. In reality, the dependence of non-parental conversation rates on host population sizes is more complicated than the two terms suggest, and the nature of the dependency would need to be studied empirically as part of any detailed mathematical modeling effort for memes with significant non-parental transmission. As with the parental terms, the non-parental conversion terms may be simplified in some cases by replacing the age dependencies with "lumped" effective propagations at certain effective ages.

The following two terms (beginning of line 3) express the "spontaneous" dropout rate for meme-1 and meme-2, respectively. "Spontaneous" dropout rates are assumed to be proportional simply to the number of hosts capable of dropping out. Such rates could also be modeled as age-dependent rates by replacing λ_1 with $\lambda_1(a)$ and λ_2 with $\lambda_2(a)$.

The next term is the partial derivative of $N_1(a,t)$ with respect to a . This term indicates that part of the changing population age profile of meme-1 is due to simple aging of its host population. The final term expresses the mortality rate as a function of age among meme-1 hosts. Mortality per host per year at age a (a kind of actuarial data) is simply multiplied by the number of hosts at age a to give the overall rate.

Equation 2 above models the same kinds of propagation processes for meme-2 as are modeled for meme-1. Equation 1 and equation 2 form a system of non-linear differential equations modeling the interdependent propagation of meme-1 and meme-2.

What follows are five more equations that go with equation 1 and equation 2, defining relationships between the propagation parameters. Equation 3 states that all offspring of meme-1 parents end up holding either meme-1 or meme-2. Equation 4 says the same thing for meme-2 parents. Equation 5 and equation 6 state that one group's non-parental conversion gains are the other group's non-parental conversion losses, so that the net non-parental gain to the whole population is 0. The last equation (equation 7) merely defines the function $N(t)$, the total population versus time, as the sum of the as the sum of the two meme host populations, all ages included.

$$(3) \int_{\tau=0}^{\tau=a} [K_{11}(p, \tau) + K_{12}(p, \tau)] d\tau = 1, \quad a > 0$$

$$(4) \int_{\tau=0}^{\tau=a} [K_{22}(p, \tau) + K_{21}(p, \tau)] d\tau = 1, \quad a > 0$$

$$(5) \gamma_{12}(p, a) + \gamma_{21}(a, p) = 0 \quad \text{for all } a, p$$

$$(6) \beta_{12}(p, a) + \beta_{21}(a, p) = 0 \quad \text{for all } a, p$$

$$(7) \quad N(t) = \int_0^{\infty} [N_1(a, t) + N_2(a, t)] da$$

Not all meme propagation events are given their own separate terms in equation 1 and equation 2. For instance, if it frequently happened that meme-1 hosts produced meme-2 offspring who then converted their parents to meme-2, then the rate at which meme-1 hosts were non-parentally converted to meme-2 might depend greatly on how many children they had. A new term might have to be added to the equations to make this phenomenon adequately modeled. The model can, in fact, be made arbitrarily complex, but it is obviously desirable to keep it as simple as the application permits.

Another elaboration of the equations, and one that might interest mathematical sociobiologists, is the explicit inclusion of specific genes and their propagation parameters into the picture. Such a model would analyze "host populations" of memes, genes, and meme-gene combinations all in the same system of equations. Of course, one sets the λ 's, μ 's, and ν 's to zero wherever the propagation of a gene is modeled. The parental terms become more numerous and take on a diversity of forms corresponding to all the combinations of genes and memes that can occur in two mating adults. Keeping track of the homozygous and heterozygous combinations would also cause more population parameters and equations. Each possible outcome of each parent combination must have its own term in one of the equations. Such equations embody no *a priori* assertions about the relative importance of either genetic change or cultural change over a modeled time span, nor any assertions of how strongly or weakly prior genetic and cultural evolution constrains the course of change over that time span. Instead, they allow for considering these matters on a case by case basis once the requisite starting data are fed into the models. Although emotional and cognitive receptivity factors are not readily conspicuous in equation 1 and equation 2, they are in fact represented. The reason is the K 's, λ 's, and ν 's are measures of *successful* meme transfer events. As such, they are composites of both the rates at which propagation is attempted and the rates at which it is cognitively and emotionally well-received. Likewise, the "spontaneous" dropout rates (μ 's) include their own products of cognition and emotion.

Anti-competitor propagation advantage, on the other hand, is not fully represented by the K 's, λ 's, and ν 's. Part of the reason is that this mode can occur in quite a wide range of ways. It makes a big difference, for instance, whether the meme-1 group merely bans meme-2 proselytizing or launches a meme-2 extermination campaign. Moreover, the effectiveness of such measures does not vary as a simple function of the meme host populations. The Nazis, for instance, became dramatically more harmful to competitors after they became numerous enough to gain political power. Such phenomena may well defy mathematical modeling techniques based solely on predicting host populations versus time, and require the detailed modeling of political processes as well.

The K 's, λ 's, and ν 's are each modeled as overall *effective* rates of meme transmission. The K 's, for instance, do not indicate how many times a parent needs to repeat a message to her children before it is effectively learned. The λ 's, and ν 's likewise do not reflect how many a message was voiced from hosts to a non-host before that non-host converted. A more detailed model might therefore break down these parameters into the subfactors of *transmissivity*, a measure of how often each host attempts to transmit a meme, and *receptivity*, a measure of the likelihood

each host to non-host transmission attempt has of actually imparting the meme to a new person. Much research has been done on how various components of receptivity affect the diffusion rates of innovations [15]. Receptivity parameters can also be broken down to reflect different probabilities of meme acceptance on first, second, third, etc. exposure. Modeling meme-based *differences* in receptivity to meme-1 or meme-2 that result from the presence or absence of third or fourth (etc.) memes requires expansion to more than two main equations, but may be necessary in cases where the empirical evidence suggests that non-host populations have both "susceptible" and "non-susceptible" subsectors. Such elaborations generate more complicated mathematics.

All meme propagation involves some level of transmissivity, receptivity, and longevity of the memes. Memetic evolution arises from differences in transmissivity, receptivity, and longevity¹⁴. One of the differences between memetics and "classical" social science is that memetics looks at all three of these general factors, while the classical social sciences often neglect transmissivity and longevity in favor of receptivity. Though pre-memetic social sciences do acknowledge transmissivity differences in mass media, questions of why a whole society came to believe something are often posed as questions of "why did the people want to believe". Investigating such questions does provide useful information, but not a complete picture. Equation 1 and equation 2 model fairly ideal cases of the two-idea propagation problem, but also serve as the kernel of a multi-equation system for cases involving three or more memes with host populations N_1, N_2, N_3 , etc. The equations offer a sample of the kinds of terms that can arise in realistic applications, and they illustrate that a unified quantitative analysis can be given to qualitatively dissimilar modes of propagation. They also illustrate the concept that once the main mechanisms of an idea's propagation have been empirically discovered and measured, the degree to which each mechanism contributes to instantaneous rates of propagation can be mathematically modeled. The resulting systems of differential equations govern host populations as a function of time, and so can be used to generate limited predictions of what will happen if the equation parameters remain reasonably constant in non-chaotic intervals.

The model presented above treats each meme as being either instantiated or not instantiated in a given person. An alternative is to model ideas as a continuum, in which there are an infinite number of mutually exclusive degrees of "hostship" that are instantiated or not. In other words, each individual is considered to occupy a single point on an ideological continuum. Strictly speaking, it would no longer model "replication". Instead, each point on the continuum would exhibit its own birth and mortality rate. Parents at each degree of the trait would have a distribution of rates of imparting all possible degrees of the trait to offspring. People communicating with non-offspring would have distributions of second-party transfer rates denoting how often they move people from one level of the trait to any other level of the trait. Yet in measuring such continuum traits, investigators generally end up assigning subjects to a finite number of trait levels such as "strongly agree", "agree", "neutral", "disagree", and "strongly disagree", designated here as mnemons A, B, C, D , and E , respectively. This returns us to dividing the total population into five (or alternately, seven, ten, etc.) mnemon host populations with a corresponding number of equations. Still, horizontal communication can involve heterogenic events in which, for instance, someone in the "strongly agree" category gets someone in the "disagree" category to transfer to the "neutral" category. As noted earlier, not all memory items are memes with respect to the abstraction system in use, and an abstraction system

using finitely stratified categories would include both memetic and non-memetic (heterogenic) events. However, certain unidirectional multistage heterogenic events can add up to form homogenic (memetic) events with multiple participants. If, for instance, four distinct E -hosts convert an A -host into an E -host with in stages (a separate E -host participating in each stage), then the heterogenic stages still add up to a homogenic event. The first three events taken individually are heterogenic: $A+EB+E$, $B+EC+E$, and $C+ED+E$. Only the fourth event $D+E2E$ is homogenic by itself. Yet the overall sequence adds up to the net event $A+4E5E$, which is homogenic with respect to E , and hence potentially recursive. Other events, including ones going in the opposite direction (e.g., $E+4A5A$), are also potentially recursive. The potential for recursively shifting large segments of population to higher levels of agreement or disagreement would be inherent in the system of five equations for the host populations of A , B , C , D , and E . The question of which, if any, of the potential recursive events predominate would be determined by the measured event rate functions (generalized 's, and 's) used in that system of five equations¹⁵.

Returning to non-stratified memes, a great many phenomena that may look like two-meme problems are in fact applications calling for three or more equations. This includes cases that enumerate not only the hosts of a meme, but also the exposed and unexposed non-hosts. For instance, if we define mnemonic P as *belief* in proposition X , then non-belief is $\sim P$. If *awareness* of proposition X is designated as Q , then unawareness is $\sim Q$. An exposed non-host of the proposition is designated as $\sim P^*Q$. Exposed hosts are P^*Q . Unexposed non-hosts are $\sim P^*\sim Q$. The $P^*\sim Q$ combination presumably has a host population of zero. The resulting mathematical model therefore has three equations modeling N_1 hosts of $\sim P^*\sim Q$, N_2 hosts of $\sim P^*Q$, and N_3 hosts of P^*Q .

Host populations modeled as distributions in age and time in equation 1 and equation 2 can also be measured and modeled using a variety of additional parameters such as those of geography (e.g., longitude and latitude), duration of hostship (as distinct from the age of the host), family income, years of schooling, etc. The R 's, K 's, 's, 's, 's, and M 's could be modeled with the additional parameters as well. The R 's, K 's, 's, 's, 's, and M 's would then quantify a range of events that include individuals changing not only their belief their host status, but also individuals changing their locations, incomes, etc. The corresponding event diagrams would include non-memetic attributes, such as location coordinates x , y , and z , so that the simple migration of a meme P^*Q host from location 1 to location 2 would become $P^*Q^*(x_1, y_1, z_1) P^*Q^*(x_2, y_2, z_2)$. The modified a's could then quantify this migration event in addition to memetic events such as $P^*Q^*(x_1, y_1, z_1) P^*\sim Q^*(x_1, y_1, z_1)$.

As an alternative to working with systems of difficult equations, one can also use quantified propagation mechanisms to run predictive computer simulations of memetic evolution without the intermediate step of writing down differential equations. The latter method can run particularly well on systems based on generalized cellular automata, where each "cell" simulates the memetic state and behavior of a person. Such an individual-based computer simulation is now feasible using the *SWARM* program developed by the Santa Fe Institute [8].

17 Qualitative and Quantitative Evolution

As mentioned earlier, occurrence rates of heterogenic events often depend on the prevalence of precursor memes. When vigorous precursor memes proliferate, they achieve substantial odds of causing the creation of memes that only a rare host can form. Additionally, when the new meme is simply *defined* as a combination of two or more precursor memes, the vigorous propagation of the precursors greatly hastens the arrival of the combination. So the independent spread of meme X and meme Y hastens the formation of the combination $X*Y$. Indeed, if X and Y spread vigorously, $X*Y$ can pop up explosively among many widely separated individuals. So if $X*Y$ tends to inspire hosts to create mnemonic Z , then Z , too can pop up explosively among widely separated individuals. This much acclaimed feature in the innovation of ideas shows that creativity is largely a population phenomenon.

The most vigorous precursor memes tend to recombine with more varieties of new ideas, some of which form an even more vigorously propagating meme package in combination with the precursor set. Mnemon variation thus feeds new operands into the quantitative processes of natural selection while the quantitative processes give many subsequent qualitative variations an appreciable chance to occur. The two kinds of change continuously feedback on each other to form a genuine process of evolution. A recursive process therefore happens at a higher level than that of individual mnemonic replications. This is the iterating cycle of variation and selection that Dennett [5] describes as an *algorithm*. It is, more specifically, a *recursive algorithm*, a central feature of all evolutionary replicator theories.

18 Falsifiability

The sort of predictions generated by mathematical models and computer simulations are falsifiable. This provides a general method for attempting to falsify specific memetic hypotheses. In general, propagation parameters can be measured over the duration of the time interval being modeled, as can the initial host populations of the memes under study. If the propagation parameters remain in some specified interval, then the final host population plus or minus a calculable error margin should be measured at the end of that interval. A host population measurement outside those error margins would then falsify the model being used for the specific memes under study. The procedure can be quite elaborate, as it involves conducting surveys and performing difficult computations.

Yet particular aspects of a specific memetic hypothesis can be falsified by less elaborate means as well. If a proposed model for the spread of anti-abortionism hypothesizes that the belief "abortion as wrong" leads adherents to raise more children than non-adherents, then the whole model could be falsified by, for instance, showing that non-adherents raise equal or greater numbers of children. If such data were gathered, and proven representative of whole societies over long time spans, then there would be no need to begin the more elaborate procedures of measuring additional parameters and performing computations.

In some cases, this method can be performed using existing data sets. For example, the National Health and Social Life Survey [9] contains data about respondents' attitudes toward various sex acts. It also has data on reproductive histories. So, after making suitable functional definitions

based on the questionnaire, one can statistically reanalyze the raw data set to see how much of the variance in reproductive history is attributable to variance in a particular attitude response. Applying the method to the older respondents could provide results that tend to either corroborate or falsify a hypothesis that a particular sex taboo, for instance, increases its hosts' average number of offspring¹⁶.

The overall theory would conceivably be falsified by refuting its premises or the logic and mathematics based on those premises. The assertion that memetics is a *useful* theory is also falsifiable, for instance by showing that differences in propagation parameters are *never* great enough to account for large-scale ideological shifts, or that the only parameters that ever account for large-scale ideological shift are the "classical" receptivity parameters.

19 Other Empirical Issues

At present, there is no brain scanning device that tells unambiguously whether someone holds a particular belief or not. Nor is there a memory probe that recovers all the communications that lead someone to adopt a particular idea. This means that measuring host populations and propagation parameters must depend on survey methodology. Questionnaires and interview protocols may thus form functional definitions of the abstractions used in memetics.

The rates of occurrence of specific events must also be measured for use in a quantitative model, in order to determine the propagation parameters. Surveys already exist which ask how many children people have. Parent to child meme transfer rates would have to be measured by new survey designs that interview both parents and offspring. Human subjects would in general have to be asked to remember what roles their friends or parents may have played in imparting specific beliefs. Respondents "crediting" their parents or people the parents designate on the basis of memetic similarity would be counted toward a meme's parental transmission. Respondents "crediting" other people would be counted toward the meme's non-offspring conversion rate. Much work and proper funding are needed for such surveys.

In a few cases, raw data may have been incidentally gathered for entirely different purposes. The Mormons, for instance, have kept unusually extensive long-term records not only of member births and deaths, but also of how many children followed their parent's faith and how many dropped out, as well as which members arrived through non-parental conversions [10]. A project to re-tabulate such data by types of events should enable the calculation of parameters for use in the above differential equations or computer simulations. The resulting host population versus time figures can then be compared to the records of total membership also culled from church records.

With non-human animals, behavior and communication can in principle be monitored with tiny, individual electronic recording devices and studied in detail later. The method is ethically encumbered for humans, but some useful propagation data may still emerge in limited consensual monitoring studies. Though it gets past some of the limitations of surveys, it is still an enormous project.

Small recording devices may also be used in animal experiments in memetics. Bonner has documented the imitational spread in British titmice of the learned skill of pecking through foil caps of milk bottles delivered outside of houses [2]. A more deliberate experiment could place a large number of smaller artificial food containers throughout an extended (perhaps closed) environment and monitor them. They would be designed so as not to resemble any previous food source, but would be easily opened by the species under study. A container that looks like a distinctive pebble but can be pecked open in a particular spot might do. (To study multiple modes of transmission, care may have to be taken to insure that a single bird cannot have too many imitators in a single feeding, or else the meme will spread to saturate the population under study in less than one generation. Limiting the food per container and choosing a solitary-foraging bird may be necessary.) A large display screen with computer-simulated images of birds opening the containers and eating from them could then be used to release a synthetic meme into a small initial host population. Subsequent monitoring of the birds for reproductive rates, death rates, parent to offspring imitation rates, non-offspring imitation rates, and "forgetting" rates could yield useful parameters that differ between host and non-host populations. Observed host and non-host population sizes versus time can then be compared to those predicted using the quantitative theory and measured parameters.

Human society also affords some specialized environments in which to investigate memes by investigating meme relics. Modern libraries, for instance, allow us to track the proliferating citations of scholarly papers indexed in a computer database. Pocklington and Best [1, 14] have also provided strong evidence of meme proliferation by demonstrating the corresponding proliferation of meme relics on the Internet.

Some look at the lack of a strictly physical definition of meme instantiation as reason for dismissing memetic evolution entirely in favor of theories that describe the same phenomena in terms of genes. Genes, after all, have reliable molecular definitions and are detected using impartial technologies such as nucleotide sequencing. One problem with this argument is that even genetic psychology theories still require functional definitions of psychological features as abstract as a meme. Thus, if an evolutionary psychologist hypothesizes that the valuation of female premarital chastity is genetically based, the empirical investigation must include a method of deciding which females value premarital chastity and which females do not. Then some specific genetic factor must be linked to the presence or absence of this trait. It should, moreover, not just be responsible for learning in general, as the same gene would then account for the ability to learn either the valuation of chastity or the valuation of promiscuity. Rather, it should be a genetic factor whose phenotype and evolutionary adaptation can somehow be more specifically identified with chastity preferences than with strong sexual cravings or cerebral functioning in general.

In many such cases, memetic hypotheses are on empirically *stronger* footing than alternative genetic psychology hypotheses. We can, for instance, *observe* the hypothesized memetic replication event of parents telling sexually eager daughters to "say no". Yet no one has identified and *observed* a gene that makes daughters want to repress the sexual urges brought on presumably by other genes. The memetic hypothesis involves parents feeling economically motivated to impart the meme to daughters and having more grandchildren when they do so [12]. It is, in essence, as much Darwinian as the genetic hypothesis is. Yet the memetic hypothesis is

more parsimonious: a competing genetic explanation must still account for the *observable* communication of sexual repression messages from parents to daughters.

When a communication event is *not* observed, however, it can serve as indirect evidence of genetic influences. For instance, if parents and others are consistently observed *not* teaching their daughters any preferences for male lower body physique, but daughters develop their preferences anyway, then a genetic hypothesis for such preferences is on stronger footing than a memetic hypothesis. Specific genetic factors still need to be identified to completely validate this hypothesis, but it at least does not face a stronger and more parsimonious memetic alternative. Memetics does face methodological challenges in measuring prevalence and propagation parameters that are more complicated than the functional issues in polling. Yet these should not be seized as arguments for the universal superiority of genetic theories.

Conclusion

Even physical scientists routinely take the existence of human "memory items" and "ideas" as a given. They even accept the concept that there is such a thing as "communication", in which one person can "cause", by complex means, the occurrence of an "idea" or "memory item" in another person. Sometimes the newly caused "memory item" in the other person is even considered to be "the same" as one in the former person, an event called "replication" by Dawkins and others. Replication events include many cases where participants assume the ideas to be playing very passive roles in causing new instantiations of "the same" ideas.

Yet even physical scientists again routinely assume that "ideas" can influence "behavior", including "communication behavior". When an "idea" causes "communication behaviors" that result in a new instantiation of "the same" idea in a different person, we have a generalized kind of autocatalysis, or "replication", in a stronger sense of the term. It is a stronger sense of the term "replication" primarily because these special-case ideas are seen as playing a stronger role in the causation of "the same" idea in new individuals. Ideas which play such strong causal roles in their own replication can thereby gain extreme prevalence and influence in a population. Moreover, their propagation results in the formation of new varieties of strongly replicating ideas. These observations cause dismay in many who have become accustomed to viewing themselves as controlling their ideas rather than the other way around, but major advances in scientific theory have often caused initial discomfort. The new theory offers a strong and parsimonious understanding of diverse phenomena in the areas of religion, sexual ideology, family structure, health beliefs, war, fascism, and numerous others. The theory of evolution by natural selection of memes is thus a solid and broadly unifying theory whose time has come.

Acknowledgments

My gratitude goes to Carl Wegner for his early support of my memetics work.

Thanks also to Daniel Dennett, Valla Pishva, and Walter Cuirle for valuable comments on earlier drafts of this paper, and to Curt Hicks and Michael Crowley for contributing their time and talent to the 1991 precursor of this paper. Thanks also to Richard Pocklington, Kieth Henson, and Mario Vaneechoutte for engaging me in on-line discussions that in 1997 sharpened my thinking

for this expanded treatment, and to the anonymous reviewers who likewise contributed their insights. Special thanks to publisher Bruce Edmonds for working patiently and diligently with this long paper.

Notes

1. From Dawkins [4], p. 109.
2. See the discussion of the meme for bifocals in Dennett [5], p. 353.
3. "Mnemon" is being introduced as a neologism here, and may differ in meaning from the word as coined elsewhere for use in other fields.
4. The term *ideosphere* was co-invented by myself and Douglas Hofstadter. See *Metamagical Themas* by Douglas Hofstadter [6], p. 66.
5. Dawkins [4], uses the term *phenotypes* in connection with memes to describe the "outward and visible (audible, etc.) manifestations of the memes within the brain".
6. See Dawkins [4] p. 112.
7. See Dennett [5], p. 346. He uses this statement as a pithy summation of the memetic perspective, whereas I regard it as an example of what memetics is *not*. Libraries do indeed help scholars to write new books, and the production of new books plays a crucial role in causing the formation of new libraries. In this sense, libraries can be treated as cultural replicators that use scholars (among other things) in the process of replication-especially as the abstraction "library" does not call for even a single shared volume between "parent" and "daughter" libraries. But the phenomenon captures only the *flavor* of memetics, as the library itself is not a meme.
8. See Dennett [5], p. 369 for the summary of chapter 12.
9. Colony sizes here come from Hostetler [7], p. 188, Table 1, which presents demographic charts of a colony branching event in 1969.
10. Dennett [5] argues effectively on pp. 473-475 that the Hutterites exhibit a striking *clash* between memes and genetic proclivities.
11. This argument is spelled out more completely in [13].
12. If there is a non-zero rate of completely "spontaneous" dropouts in the model, then it is technically more accurate to use the terms "mnemon-1" and "mnemon-2" in place of "meme-1" and "meme-2".
13. The population age-time profiles [$N_1(a, t)$ & $N_2(a, t)$], fertility rates [R 's], child inculcation rates [K 's], non-parental conversion rates [λ 's, and μ 's], and mortality rates [M 's] are represented as distribution functions, but this does not mean that smooth continuous functions

will ever emerge from the data gathered for an actual application. Rather, age and time will be divided into discreet intervals such as a month, a year, or a decade. The population age-time profiles, fertility rates, etc. will then be the kind of functions often represented with 2- or 3-dimensional bar graphs. The specific time and age resolution ("granularity") used in data gathering will in general have some effect on the accuracy of computational solutions to equation 1 and equation 2. This is because differing ways of subdividing time and age into discrete intervals amount to making different approximations of the functions in these parameters. Conversely, the required accuracy plays a key role in determining just how finely time and age must be partitioned into intervals to gain useful data for a specific application. Once such a partitioning is chosen for a given application, the distribution functions in time and/or age take on a finite number of measured [R 's, K 's, 's, 's and M 's] or computed [$N_1(a,t)$ & $N_2(a,t)$] values and the integrals may be reduced to finite summations for computational purposes. The present treatment does not use any specific time/age partitioning scheme, because the optimal scheme varies across applications. Hence, functions are left in their short-hand form rather than as data sets for fertility rates, child inculcation rates, non-parental conversion rates, and mortality or computed result sets for population age-time profiles. (The a 's are treated as constants, but they too could be measured as functions of age a .)

14. The term "longevity" might be replaced by "durability" to better signify the resistance to dropout and mortality.

15. Recursive multistage events such as the ones that add up to $A+4E - 5E$ or $E+4A - 5A$ are especially likely to predominate if people at the extremes ("strongly agree" or "strongly disagree") play a preponderant role in persuading others to take those small steps of unidirectional mnemonic change. The circumstance is probably common. Sequences of heterogenic events adding up to smaller recursive homogenic events such as $C+2E - 3E$ and $C+2A - 3A$ might happen most frequently, because they do not require shifting an individual from one extreme to another-although there are individuals who go from one extreme to the opposite on a topic. To model all possible two-party conversion events for $A, B, C, D,$ and E where only one participant changes mnemons requires 80 event rate functions (160 if both b and g types are used), but measurement could determine that many of them are negligible in a given application.

16. I say "tend to either corroborate or falsify" because there remains the possibility that a taboo that increased reproduction for thousands of years no longer does so, or that a taboo that had no effect for thousands of years suddenly made a difference in the 1994 data.

A LETTER ON: RATIONALES FOR MATHEMATICAL MODELING AND POINTS OF TERMINOLOGY

By
Aaron Lynch
aaron@mcs.net

Michael Best opens his *Critique of Memetic Models* letter (Best, 1998) with what might be taken as a broad swipe at new science being done under the heading of 'memetics'. Yet Best has himself published in this journal (Best, 1997), using a very recent definition of meme and very recent methods. So it might seem surprising that he should now proclaim a sweeping 'weakness' in memetics models or cast doubts over thoughts of 'new science' in the field.

The letter does not mention, however, that my *Units, Events, and Dynamics* paper (Lynch, 1998) finds a wide range of meme definitions, including his, functionally encumbered and contrary to Dawkins (1982). In particular, the considerations in section 12 of my paper find an unrecoverable problem in the broader usefulness of definitions based on the embedded theoretical construct of 'unit size', because sets of proposed cultural units can in general only be considered partially ordered in the set theoretic sense when applied to human memory items. This affects both 'smallest units' and 'largest units' definitions of the word 'meme'. My paper also maintained that to avoid terminological confusion, we should remain consistent with Dawkins's clarification that memes are informational replicators *residing in the brain*. These were matters of terminology, rather than criticisms of Best's empirical netnews findings or the findings of many others who have used vastly divergent definitions of the word *meme* or different words altogether. I even proposed a more general term than memetics, namely, *cultural repliconics* to encompass the study of divergent kinds of non-brain based replicators. I also favor inserting the word *and* into the title of this journal to emphasize its inclusion of the broader scope of evolutionary cultural replicator theory: *Journal of Memetics and Evolutionary Models of Information Transmission*. Still, it is possible for one to misinterpret a merely terminological discussion as a declaration that researchers along the lines given by Best are 'memetics outsiders'. One might further conclude, then, that papers such as Best's cannot, by definition, be considered exemplars of 'weaknesses' that he presently claims to see in memetics. This possibility diminishes the surprise we might feel about broadly condemnatory tone in Best's opening remarks. The rest of his essay, however, shows a variety of serious flaws which I address severally.

Best's first specific complaint was that the *Units, Events, and Dynamics* paper should have cited Campbell (1974) for first proposing the term 'mnemon', even though Campbell does not use this term. Campbell (1974) does use the phrases "*nonmnemonic problem solving*" and "*mnemonically supported thought*", but does not use or introduce the word "*mnemon*". Nor does Campbell indicate that the substring 'mnemonic' means anything other than 'pertaining to memory'. The term 'mnemonic' is sufficiently old that derivatives such as 'nonmnemonic' and 'mnemonically' do not warrant special citation in the context of my paper. Nevertheless, a few words about the derivation and history of the word 'mnemon' are in order. Although I formed the word from its Greek roots, this should be recorded as a reinvention of a word that was once coined before in a physiology article about engrams (Cherkin, 1966). That 1966 term, which does not seem to have

gained wide use, was originally defined as "*the minimum physical change in the nervous system that encodes one memory*". It is not defined as something that is 'the same' from one organism to another. Because I derived the term "mnemon" from its Greek roots and gave it a different meaning, it would have been inaccurate to attribute my usage to Cherkin. Nevertheless, my paper might have benefited from some mention of the prior use of 'mnemon' by Cherkin, especially as this may have prevented any suggestion that I was plagiarizing Campbell.

It would also have been interesting and informative to include a paragraph calling attention to the mathematical work of Cavalli-Sforza, Feldman, Boyd and Richerson, and Lumsden and Wilson in the preface to section 16 of my own paper. This is not because the equations I present are derivable from equations by these other authors, but rather, to point out that a range of models exists and to make it clear to readers that the present model differs from the others. Still, my own paper is not in any way offered as a review of literature, and should not be critiqued as such. There is much that can be said about the relative merits of different mathematical models, and why my own model is warranted in light of earlier work, but proposing a new model does not of itself require taking on the lengthy task of sorting through older models. The equations in section 16 are quite different from those of the other authors that Best has cited. They were also developed 'from scratch', rather than by borrowing from the other authors. Had it been otherwise, then failing to cite the other authors would have been a serious error indeed.

I chose to use the language of mathematics to discuss the quantitative consequences of phenomena discussed earlier in the paper. However, the transition into the mathematical language does not represent any kind of 'magic moment' at which one must always pause to give recognition to other cultural scientists who have spoken in mathematical language, when what is presently being said is not based on the previous works. Likewise, if one voices original arguments in prose, the author should likewise not be faulted for not citing non-source works that happen to use English prose for substantially different arguments. The scholarly courtesy of citing other mathematical models of cultural evolution is a good suggestion, but not mandatory in the present case. Original arguments in the language of mathematics do not have a different standard for "mandatory" citations than do original arguments expressed in prose. Unlike the physical sciences, where the use of mathematics is routine, there may be an irrational mystique about mathematics in the social sciences, but it is unwarranted.

Michael Best complains that my model fails to "*describe empirical data (present or sought)*", to which I invite readers to read the original article and consider whether host populations of memes should be considered empirical data or not. He also asserts that the equations shed no explanatory light on phenomena despite the fact that they express changes in meme prevalence in terms of rate parameters for such constituent processes as having and teaching children. As for using the equations to model a specific meme propagation phenomenon, this is indeed a more extensive project than merely publishing equations. Nevertheless, the equations are far more usable when published than when unpublished. Best fails to see the publication of equations as part of a larger process. For this, we can examine the field of theoretical physics, where equations are frequently published without yet having a specific plan to test them. We may also wish to reexamine the other works of mathematical culture modeling to see numerous examples of equations published without specific testing plans. I will not do so here, however, as I am still not offering a review of literature.

Best has further faulted the equations for modeling everything as continuous functions. Best goes on: "...even within his formalisms, Lynch is compelled to discretise time." This is confusion. I have chosen the year as an arbitrary unit of time, but I have nowhere indicated that time is an integer or an integer multiple of any quantity. Nor have I imposed any kind of discrete reproductive generations on a population. In an actual study, it will generally be necessary to choose a finite number of times at which to measure host populations, and so forth, but these details are not built into the equations themselves. They are left to the discretion of potential users of the equations. The corresponding approximate evaluation of integrals as finite summations and derivatives as ratios of differences is also left to potential users of the equations. Why Best chooses to demand formal inclusion of a scheme to "discretise time" for my equations in advance of specific application eludes me. Would he demand the same from certain other mathematical models of culture or indeed, mathematical models of physical phenomena?

Best has asked why the age of a parent (more exactly, a meme host of a given age who may have zero to many children) is relevant. The reason is that human reproduction is closely tied to the phases of our species' life cycle, so I have chosen age as the variable with which to describe phase in the life cycle. A 5-year old meme host will generally have about zero children per year, as will a 95-year old meme host. Mortality is also modeled as age-dependent, largely for biological reasons beyond the scope of this journal. Yet once the number of hosts at a given age needs to be known for one term in the equation, it must be modeled in all terms of the equation. As it happens, the rate at which many memes are learned from parents also depends on the age of the child, even if the parents' age matters little. As I have pointed out in the paper, the model can be simplified to treat each meme as being learned at just one effective childhood age and at a rate such as k_{11} that is invariant with respect to parent age. Treating k_{11} as invariant with respect to time, location, socioeconomic status, etc. is of course a simplification too.

Still another complaint that Best lodges against $K_{11}(p, a)$ regards its definition as a ratio rather than a probability. It is true that I could have defined it as the probability per unit time of meme transmission from a parent of age p to their child of age a . Correspondingly, $N_1(a, t)$ and $N_2(a, t)$ would have been defined as expectation values of host population-age profiles. This is a matter of taste. Probabilities, however, are empirically measured by taking ratios. The probability per unit time of a child of age a acquiring a meme from an age p parent, for instance, is measured by taking the ratio in a representative sample of population of those age a children with age p parents acquiring the meme in a representative time interval to the total number of age a children with age p parents. There is, however, a branch of "arm-chair theorizing" known as statistics that concerns itself with such questions as how likely it is that a parameter measurement taken on a 'representative sample' matches the parameter for the whole population to a given degree of accuracy. I have deliberately left this sort of analysis for future work. Section 16 of my paper serves only as a starting point for a particular line of mathematical modeling in population memetics, and was certainly not offered as a complete and final treatise.

As I stated clearly in the paper, "*equation 1 and equation 2 model fairly ideal cases of the two-idea propagation problem.*" Thus, I do not include certain complications that can arise from biparental transmission, such as memetically mixed marriages. So the present model works better when the proportion of meme-discordant marriages is either quite low (e.g., with certain religions) or remains constant, with reproductive rates of mixed families well modeled as the

average of the two meme-concordant cases. In the constant intermarriage case, the meme-1 partner is still credited with an $R_1(a)$ reproductive rate and the meme-2 partner is credited with an $R_2(a)$ reproductive rate. However, because some meme-1 parents' children are being partly raised by meme-2 spouses, and vice versa, we expect the measurement of $K_{12}(a, p)$ and $K_{21}(a, p)$ to show significant effects of crossover inculcation. (The reduction of K_{12} and K_{21} figures is one of the evolutionary pressures favoring intermarriage taboos in religions.)

In cases where the proportion of intermarriages changes substantially over time, or where reproduction rates are poorly modeled as a by averaging the two unmixed cases, a more elaborate modeling of parental transmission is called for. For example, a set of four equations could model the population of female meme-1 hosts, male meme-1 hosts, female meme-2 hosts, and male meme-2 hosts. A model for intermarriage rates as a function of (for instance) $N_1(a, t)$ through $N_4(a, t)$ is required, as are additional $K(p, a)$ and $R(a)$ values for meme-concordant and meme-discordant parents. (More generally, for all possible parental meme combinations being modeled. Again, the simplified k_{11} etc. parameters may be used.)

Still further elaborations can be pursued for increasingly sophisticated and realistic models. Yet even when the simpler system of equations can be used, the application of the model to a specific meme is an extensive project requiring further resources and collaboration. It is unreasonable to demand that such a project be well underway before a system of equations can even be published, but the question of how to handle two parents and meme discordance is appropriately raised at this stage. Presenting a first-order model of biparental transmission may seem a bit like treating a person as a point mass in a physics problem, but even the point-mass person is a good approximation in certain situations. However, for the most ambitious investigations of meme propagation, one should be prepared to face a degree of mathematical and computational complexity rivaling the modern models of terrestrial weather.

Best apparently demands that I model parent to child meme transmission in terms of a whole "host of factors" without being specific. Does the system of equations need to take account of every conceivable variable, or else nothing at all? If so, this could demand a degree of accuracy that would have prohibited early models of the atom as well. I agree that a whole host of variables can be added to the model, but how can one reconcile demands for a host of added variables while at the same time complaining about the "*sheer complexity*" of the model? I can only conclude from these incongruous demands that Best would have rejected any model I had proposed, regardless of potential utility. And I must ask him if he knows of a mathematical model that actually meets all of his demands, to please identify it.

The purpose of my present reply to Best's essay is not to provide details for the next and subsequent levels of elaboration to the mathematics in section 16 of my paper. At 17,100 words, the *Units, Events, and Dynamics* paper is already quite lengthy for a journal article, and elaborated models require entire new articles at the very least. Another kind of paper is one that simplifies the equations, as by taking lumped, single-event models of reproduction and child inculcation. The value of such simplifications would be to demonstrate that a particular magnitude of reproduction difference, for instance, can in principle lead to significant meme proliferation even if there are also non-parental transmission processes at work. Alternately, if even large reproduction differences never produced much long-term effect, then this may be

taken as a falsification of the hypothesis that reproduction differentials sometimes account for large relative gains in the host populations of memes. The presentation of the population memetics section in mathematical terms should be seen as an invitation to investigate such matters quantitatively, rather than by sheer guesswork. It should also be seen as a demonstration that methods do exist for translating specifically memetic theory into mathematical/quantitative terms, which is widely deemed essential to taking any variant of scientific theory seriously. An absence of such work among those concerned with "memes" could easily have been taken as a signal that in order to see serious mathematical reasoning, one must ignore those using the word "meme" in favor of those using words conceived in association with highly sociobiological tenets, such as 'culturgens' (Lumsden and Wilson, 1981). A deep suspicion exists among many scientists for lines of thought advanced without any hint of possible mathematical expression, for such efforts are widely seen as vague and evasive. In any case, Best falls far short of justifying his assertion that the mathematical model "*does damage to the problem.*" Because such phrases may discourage people from pursuing the mathematical investigations further, any claim of 'damage' should really be withheld unless strongly justified--unlike the present case where the term 'damage' is not even remotely warranted.

Best comes very close to asserting that no new mathematical models should ever be developed directly from a particular combination of concepts including 'transmission event', 'host population', 'reproductive rate', 'child inculcation rate', and so forth. Instead, he seems to assert that one must limit modeling to efforts to building upon past equations developed around substantially different premises and parameters. For this, he gives no justification, theoretical or otherwise.

Best has also seriously misread the transmission of a negatively defined mnemonic (e.g., the lack-of knowledge of birth control knowledge spreading by way of more numerous childbirths) as a "forgetting" event. Individual forgetting events are of course possible, and are a subset of individual dropout events generally (e.g., $A \rightarrow \sim A$). One can also persuade a peer to drop a belief, for instance. But nowhere in the paper is there a notion of peer to peer 'forgetting events'. Subsequent to his letter, Best explained to me that he got the idea of the transmission of lack of birth control information from his reading of the clause "*people can be taught about birth control far more easily than they can be made to forget about it.*" Apparently he didn't notice that while knowledge of birth control is discussed as transmitted, the lack of such knowledge is not. To *make* someone forget about birth control could involve drastic measures such as concussion or drug induced amnesia, or even lobotomy. Such extreme measures do not constitute 'transmission' of lack of knowledge, because 'transmission' presumes that lack of knowledge existed in the person who performed the lobotomy, drugging, etc., and that such lack of knowledge played a role in causing or directing his actions. Moreover, nothing in my paper suggests that lack of knowledge can be *taught*. Given this wild misreading of part of a sentence in section 5 of my paper, I can understand how Best would expect the worst from the whole rest of the paper. This and other misunderstandings show that before concluding that a refereed paper proposes an outlandish process divorced from reality, a few well-placed queries to the author may help.

Best barely touches upon the original disagreement he had with me, namely, the definition of 'meme'. After praising Richard Dawkins (1976), he asserts merely that 'meme' describes

"replicating cultural units." Yet Best cannot flatter Dawkins for being so nonspecific as this, for Dawkins has distinctly clarified (1982) that the word he coined refers to brain-based replicators only. Ironically, Best, whose paper and letter overlook the specificity in Dawkins (1982), now calls out for "an appreciation of past art". Yet this disagreement between me and Best is only a matter of terminology. We may have a deeper disagreement over the value of doing new work on theoretical frameworks in memetics. Yet regardless of the broader nature of our disagreements, more careful readings of my own paper and related works such as Campbell's are in order.

**MISLEADING MIX OF RELIGION AND SCIENCE:
A COMMENTARY ON GATHERER'S PAPER: *THOUGHT CONTAGION
METAPHOR IS RETARDING THE PROGRESS OF MEMETICS***

By
Aaron Lynch
aaron@mcs.net

In the abstract and the body of his paper, Gatherer shows particular concern with the incorporation thought contagion memetics into critiques of religion. In this, we see continuity with objections expressed in his paper "Meme Pools, World 3, and Averroës's Vision of Immortality" (Gatherer 1998a). There he states that "Richard Dawkins has developed his meme concept as the philosophical basis for a militant atheism," and attempts to demonstrate instead that "acceptance of the meme concept need not necessarily lead to atheism, as Dawkins and his more zealous followers would maintain." The paper also argues for a particular concept of immortality. Elsewhere in that paper, Gatherer clearly considers his religious views as being challenged and berated by those zealous Dawkinsians and "mind virology." Against this background, we can understand Gatherer (1998b) as an extension and intensification of his largely religious agenda of countering "militant atheism." We can also take it as a continuation of his critique of "mind virology," (Gatherer 1998a) which focused attention on the pejorative connotations of the term "mind virus." In both respects, Gatherer's efforts are misguided. First, thought contagion theory is not offered as a basis for atheism or as a critique of religion. It is offered as a theory of how both religious and secular ideas evolve and spread. Second, the term "thought contagion" was explicitly given a neutral connotation in (Lynch 1996a), and was even applied to socially positive ideas.

Gatherer's present method of defending religion from what he perceives as the "thought contagion/mind virus" critique is more drastic than the approach he took in his 1998a paper. He has quickly switched from accepting the memetic analysis of religious belief in (Gatherer 1998a) to treating this subject as forbidden by definition in closing his present paper (Gatherer 1998b). Exactly what happened to change his mind so quickly and sharply is unclear. However, pages 206 to 210 of his 1998a paper suggest that he was recently still unaware of the evolutionary epidemiological ("thought contagion/mind virus") explanation for the origins of prevailing forms of monotheism by natural selection, as advanced in (Lynch 1996a). Having presumably finished reading (Lynch 1996a), Gatherer now walls off all belief from memetic analysis, by redefining meme to exclude all internally stored information. This new "external" memetics then doubles as something whose progress is "retarded" by the "thought contagion metaphor." With its subject thus phrased in terms of the "progress of memetics," the article may appear to have a mostly scientific agenda rather than the religious agenda expressed in his 1998a paper, which appeared in a journal of religion and science.

Gatherer offers so many misrepresentations of Lynch 1996a, Lynch 1996b, and Lynch 1998 that I must advise anyone reading Gatherer's present paper to read my work directly to see what it really says. I do not in any way suggest that the brain has something analogous to RAM memory, for instance. Even material Gatherer presents as quotations must be double checked for context-changing distortions. For example, I do not pretend to know precisely how the brain stores

information. So I used the conditional sentence "If a mnemon resides very redundantly in someone's brain, that person still counts as only one host and one mnemon instantiation." (Lynch, 1998). In (Gatherer 1998b), the antecedent is quoted alone to give the impression that I definitely posit that "a meme - sides very redundantly in someone's brain." This becomes the basis for his assertion that I treat the brain as containing "memory banks" of awarenesses "reminiscent of a computer RAM." In correspondence, Gatherer finds nothing at all wrong with this, so I can only invite readers to check the passages in question themselves and form their own conclusions. Gatherer's present paper has so many other misrepresentations of my work that I cannot discuss them in the limited space allotted to commentaries.

The question of whether ideas, thoughts, beliefs, and opinions are valid subjects of science is yet another topic far too extensive to cover in the space of a commentary. Hard core behaviorists treat these as unobservables that cannot be independently verified. They stand in opposition to cognitive scientists, sociologists of ideology, and many others. Nevertheless, I should clarify that many instances of what I call "mnemons" are highly connected to behavior. If a rat is operantly conditioned to run a maze, then the learned and internally stored skill is a mnemon, while the actual running of the maze is not. If the rat conditions her pups to likewise run the maze, then their internally stored skill is not only a mnemon, but also a meme by virtue of being copied. In any case, memetic analysis of internally stored information does not repudiate empirical science as Gatherer suggests. I refer readers to the discussion of empirical methods and animal experiments in sections 17, 18, and 19 of (Lynch 1998).

Despite the discussion of mathematical and quantitative methods in memetics in section 16 of Lynch 1998, Gatherer claims that "Quantification became impossible." This comes partly from Gatherer's unfounded insistence that quantification requires a one to one correspondence of observed behavior to internal information. By this argument, we might as well throw out all science of operant conditioning as well, for not giving us perfect correlations between conditioning history and behavior. Or we might forbid use of antibody tests to infer the presence of HIV, again because they are imperfect and indirect. Opinion polls and various other indirect tests for internal information can, of course, be deliberately confounded. But indirect tests for internal information will be hard to escape regardless of how the word "meme" is defined. Indeed, universities use imperfect instruments called "exams" to indirectly quantify something they call "knowledge."

A wealth of original, if confused arguments permeate not only the whole body of (Gatherer 1998b), but also particular subsections, such as the section 2.6 argument that forms the basis for his claim of non-quantifiability. Consider just the passage where he attempts to show that mnemons for awareness of a proposition are impossible because having one such mnemon supposedly requires the individual to have an infinite number of them: "However, any individual who has heard of Napoleon at all will be capable of constructing and transmitting an infinite variety of mnemons of the form 'Napoleon died in x'." This demonstrates a casual lack of understanding of the term "infinite." Not only is it physically impossible for humans with finite brains to construct an infinite number of dates for Napoleon's death, but there are single numbers that humans cannot construct. If we could construct 10 digits per second for 100 years, this is still only 32 billion (32 thousand million) digits in a lifetime. Therefore, there are individual dates that cannot even be conceived. I don't claim to know just how many alternative possible

Napoleonic death dates typical people might consider--I have focused on other topics. But there is nothing to my work that requires the number to any greater than the number of years of recorded history, let alone infinity.

Gatherer goes on to claim that treatment of beliefs as memes "lacks explanatory power." While many people who do not wish to see their belief systems explained in terms of evolutionary epidemiology may feel drawn to this position, I must again recommend that scientists read works such as (Lynch 1996a, Sperber 1996, Balkin 1998) and others to decide for themselves. Does internally stored information about numbers of players to recruit explain why baseball out-propagates tennis in the U.S? You have to read (Lynch 1996a) for yourself. Gatherer asserts that "To say that behaviour can be explained in terms of something which cannot be observed (e.g., beliefs) is unhelpful." Has he never told anyone "I wasn't there because I thought the meeting was tomorrow"? Anyone who makes such a statement is explaining their behavior in terms of something that, according to Gatherer, cannot be observed. If one person's belief causes behavior that leads to another person having the same belief, then this is the replication that makes the belief a minimal meme contagion. So if Gatherer ever explains his actions in terms of beliefs acquired from someone else, then he is going back on what he has said in focus item C. Still, if anyone tried to call meme contagion the totality of psychology, then they would indeed "trivialize psychology." But it is a gross misrepresentation to suggest that my work does so.

My initial reaction to Gatherer's 12,000 word paper was to type my numerous rebuttals as red text in the html file. Those comments took up far more space than is allotted for our journal's commentary format. So I instead offer this shorter commentary that barely adheres to the 1500 word limit. Besides, a careful reading or re-reading of (Lynch 1998, 1996a, 1996b) would probably clear up any confusions imparted by reading (Gatherer 1998b) much more efficiently than reading a paragraph by paragraph rebuttal. Suffice it to say that I still consider "internal" memetics highly tenable despite Gatherer's attempt to persuade otherwise.

A RESPONSE TO PAUL MARSDEN OF A REVIEW OF *THOUGHT CONTAGION: HOW BELIEF SPREADS THROUGH SOCIETY*

By
Aaron Lynch

Marsden's (1999b) review of my book *Thought Contagion: How Belief Spreads Through Society* listed numerous supposed flaws in the text, but failed to mention the one real flaw most crucial to readers of JASSS. That flaw, imposed by standards of simplicity in the trade book market, was the complete omission of technical, mathematical and quantitative material I had published earlier and submitted as a pair of appendices. A serious gap in the coverage of the book arose from the fact that the mathematical population memetics analysis (Lynch 1991) could not be included even as an appendix. The system of non-linear, partial differentio-integral difference equations for host population as a function of time would have provided a good method of parameterisation for simulations of interest to JASSS readers. The definition of a "meme" as a "homoderivative mnemonic" (memory item caused by prior instantiation of the same memory item) would also have lent a technical clarity that JASSS readers could utilise. Moreover, the non-metaphoric event diagrams used in that paper could have formed a useful conceptual framework from which to design memetic simulations. Yet Marsden has previously mislabeled the equations (republished in Lynch 1998) as "... arbitrary mathematical manipulations ..." and the event diagrams as "... laws of combination and permutation ..." (Marsden 1999a). So we should not be surprised that he has not flagged their absence as a serious flaw. The 1998 edition of this technical, mathematical and quantitative population memetics (Lynch 1998) even receives further negative commentary in Marsden's review of *Thought Contagion*.

Other aspects of Marsden's review demonstrate that by carefully choosing which sentences and sentence fragments to quote or misquote out of context, and how to mislabel them, one can make any book look totally silly. So I invite JASSS readers to read chapter 1 of *Thought Contagion* online and judge for themselves whether the book's opening is really as silly as Marsden makes it look.

While Marsden's review does mention topics covered in *Thought Contagion*, his portrayal of my analysis is misleading to say the least. For example, there really is a section on the evolution of memes pertaining to homosexuality (p. 79-84). In a nutshell, it says that adherents of the taboo out-procreated more tolerant people over the course of many generations in ancient times, leading to increased prevalence of the taboo. (This does not require anything like a perfect correlation between morality and behaviour, or a perfect child inculcation rate, but only enough to increase taboo prevalence by several percent per generation over hundreds of generations.) Then *horizontal* transmission kicked in as people maligned homosexuality to "prove" their adherence to the taboo. As the taboo becomes extremely widespread, most homosexuals live heterosexual lives, leading them to reproduce any genes involved. As these genes gain prevalence, the rate of taboo dropout increases. Gene carriers who have dropped the taboo are more sexually and socially motivated to spread acceptance of homosexuality than are non-gene carriers who drop the taboo. So the rising gene prevalence can lead to a self-sustained propagation of pro-gay memes. (Horizontal transmission again, contrary to Marsden's claim that I ignore this mode.) That, in turn, can lead to lower gene prevalence in the next generation, and

even lower prevalence of pro-gay memes. All of this leads to potential fluctuations over long time spans. Incidentally, there is a brief mention of the way that beliefs about anal sex become involved with homosexuality taboos. Yet despite a multi-faceted discussion of homosexuality taboos, Marsden excerpts a sentence on anal sex and presents it as if I had offered it as the answer to the question "What memes deter homosexual behaviour?" He has thus taken a complex argument and misrepresented it as childishly silly. He uses a similar distorting approach in all of his other indented excerpts.

The "appendix" in which Marsden supposedly lists "Lynch's Seven Modes of Memetic Transmission" in the same indented format is not based on excerpts at all. There, the wording of each mode is Marsden's, and phrased so as make a mockery of what is actually said. Finding out what I actually said, however, is as easy as reading chapter 1 online. For example, it would have been simple for Marsden to quote me directly as saying "Any idea influencing its hosts to have more children than they would otherwise have exhibits *quantity parental* transmission." (p. 3) Instead, he misrepresents the label I give to a natural phenomenon as being an inane exhortation to "Have lots of children and use your position of authority to indoctrinate them and increase the prevalence of your beliefs." Marsden likewise misrepresents all of the other transmission modes, mostly as exhortations to the reader.

Under proselytic transmission Marsden even attributes to me (without page reference) a vague and incomplete statement that "A belief that spreads will spread ..." (ellipsis is Marsden's). This directly contradicts what the book actually says: "Proselytic thought contagion becomes self-limiting as host population growth diminishes the supply of nonhosts. Few nonhosts remain by the time the host population is a great majority since most have already converted by then. Without enough nonhosts, especially persuadable ones, the proselytizing cannot win many new adherents. This creates cycles in which successful proselytic movements lose momentum, setting the stage for renewed outbreaks of old movements and initial outbreaks of new movements" (p. 6). In other words, many beliefs that spread will therefore stop spreading or even go into decline. In order to find *Thought Contagion* a "spectacular failure" in putting memetics on a more serious footing in the sciences, Marsden not only misrepresents what it says, but also demands that the book serve a far broader function than it claims to serve. In the first sentence of the preface, I state that the book "... introduces a new branch of science dealing with ideas that program for their own retransmission ..." (p. vii) That is, ideas that gain propagation by influencing or manipulating adherent's idea-propagating behaviours. It is *not* offered as a general theory of cultural evolution, nor a general theory of social contagion. Even within the subject area of memes, the focus is not on the field in general, but rather, on the small but important subclass of memes that play a particularly active role in causing their own retransmission. For example, in my discussion of how my work relates to that of Durham (1991), I state "Yet Durham admits that in special circumstances, memes can depart from the mainline rout to prevalence. Such 'special case' memes are the ones I call *thought contagions*". (p. 25)

Some take a very expansive definition of the word "meme" and envision "memetics" as covering almost all topics in social science and social philosophy, for instance whether the self is an illusion (Blackmore 1999). For them, *Thought Contagion* may indeed be a disappointment. Yet the scientific community is by no means united behind Blackmore's vision of a universal memetics, as exemplified by a scathing review in *Nature* (Coyne 1999). This leaves a valuable

role for my own more modest and scientifically conservative agenda of demonstrating that there are a reasonable number of phenomena that really call out for the evolutionary replicator analysis of self-spreading brain-stored information. Like Rogers (1995), I narrow my focus to discuss only a subset of cultural evolutionary phenomena, and this does not call for a thorough survey of literature in the broader field as Marsden seems to imply.

Contrary to one of Marsden's misquotations, I do not claim that my brand of memetics is "the missing link" in the social sciences. The phrase "the missing link" does not appear anywhere in my book, and for good reason. *Thought Contagion* expressly emphasizes that memetics should *not* be taken as a replacement to existing social science. In the preface, it says "Thought contagion theory considers mainly the question of how ideas program for their own propagation, and the consequences for cultural evolution. This is an important and long overdue addition to social science, but it is hardly offered as a replacement for all existing social science" (p. ix). Thought contagion memetics is only called *a* missing link, and is *absolutely never* treated as the last or only "missing link" in the social sciences.

Attached to Marsden's false claim that I call my work "*the* missing link" comes another false assertion that my second chapter is presented as a "brief misrepresentation of the social sciences." The actual chapter title is "A Missing Link: Memetics and the Social Sciences." Not only does this contain the only use of the term "missing link" in the whole book, but it also clearly labels itself as something other than a survey. An honest reading of the chapter, however, reveals that it is presented as nothing more than an abbreviated overview of the relationship between thought contagion memetics to the social sciences.

As if distorting the overall purpose of the book and Chapter 2 were not enough, Marsden attempts to generate suspicion based on the 3% of that chapter given over to a discussion of "Memetics and Psychohistory". Says Marsden, "Fortunately, suspicion is likely to be aroused in even the most uninitiated reader when Lynch includes a discussion of the science fictional "psychohistory" in his brief misrepresentation of the various social sciences, in the process of claiming that his brand of memetics is 'the missing link.'" What he does not mention, however, is that the material actually emphasizes the *dissimilarities* between memetics and Asimov's popular science fiction. So I invite JASSS readers to see for themselves whether that discussion causes suspicion as Marsden suggests, or whether suspicion comes solely from the effect of Marsden's words on the uninitiated reader. To help JASSS readers decide where to place their suspicions, I copy the entire three short paragraphs alluding to "psychohistory" right here:

Memetics and Psychohistory

Some have likened memetic history to the science fiction account of a theory called "psychohistory" in Isaac Asimov's *Foundation* series. Although psychohistory did not inspire memetics, the two theories do have surprising similarities. Both theories concern *how* history unfolds, and both give more consideration to the cumulative behavior of great masses than to the actions of special individuals. Both theories can cover hundreds of generations, and both can be translated into quantitative, mathematical equations. Like psychohistory, the memetic equations can even predict "future history" given some well-measured parameters and starting conditions.

Yet the analogies start to fade from that point on. In the science fiction story, a psychohistorian can predict most of society's behavior far into the future and quite precisely. Thought contagion theory mainly considers a special subclass of ideological behaviors, and just measuring the variables can raise serious practical challenges. The quantitative translation of the theory also leads to nonlinear equations, which mathematicians and meteorologists now see as a bane to long-range forecasting.

Thought contagion memetics might never amount to the stuff of science fiction, but it can make an important contribution to the understanding of history and the human condition. (*Thought Contagion*, p. 38-39)

There is in fact so much misrepresentation, distortion, misleading assertion and poor scholarship in Marsden's review that it would take an unreasonably long line-by-line critique to expose all of it. Instead, I caution anyone who reads any part of Marsden's review to read my own work directly and see what it really says, no matter how innocent, innocuous or plausible Marsden's statements look. I also invite readers to consider the possibility that if Marsden needed so much misrepresentation in order to produce his negative review, *Thought Contagion* may actually be quite good. Indeed, contrary to Marsden's statement that there is not "the slightest risk that anybody could possibly take it seriously," *Thought Contagion* has endorsements from Richard Dawkins and Douglas Hofstadter on its cover.

It is true that the full title of the book is "Thought Contagion: How Belief Spreads Through Society: The New Science of Memes." While this may seem to claim a far wider territory than the book actually covers, I should explain that the subtitle "How Belief Spreads Through Society" is only intended to identify the subject area in general terms to people who have never heard the word "meme." The line "The New Science of Memes" is only intended to place the book in the subject area of memetics for those who *have* already heard of memes. Yet the body of the book makes clear that thought contagion memetics is a limited subdomain of memetics generally (p. 25). That may trouble those readers who hold a grand vision of memetics as accomplishing everything for culture that Darwinism did for biology, but I remain committed predominantly to the specialised realm of thought contagion memetics.

As Marsden asserts, *Thought Contagion* is indeed filled with hypotheses awaiting empirical investigation and the book warns the reader of this in advance (p. viii-ix). In the preface, I express the hope that publishing hypotheses will stimulate the research needed to test them. Likewise, the publication of hypotheses about evolution, biological contagion, quarks and other phenomena has historically played an essential part in stimulating empirical studies. In fields ranging from biology to physics, works written for non-specialists must often forego the most technical definitions of terms to achieve broader accessibility. Hence, *Thought Contagion* does not contain my most formal and precise definition of the word "meme." Yet Marsden, despite knowing my formal technical definition, seizes upon the limitations of a book written for general audiences to suggest an underlying imprecision and confusion in my use of the word. For instance, in his eighth paragraph, he refers without page reference to my statement "Because the information resides more at the community than the individual level, ownership qualifies as a kind of 'transcendent meme,' but not as an ordinary meme" (p. 19) to persuade readers that they should be "confused." In keeping with his overall pattern of presentation, Marsden distorts what I

said in a way that makes it look ridiculous: "transcendent meme" in my book becomes "*transcendental* meme" (emphasis added) in Marsden's review and out of context. (In context, the word "transcendent" is not the least bit mysterious: it simply indicates that ownership resides not in the individual, but in social entities such as communities and states that transcend the individual.) Marsden then goes on to announce that he was "no more enlightened" by reading my technical paper "Units, Events, and Dynamics in Memetic Evolution" (Lynch 1998). All of these suggestions of confusion, mystery and unenlightening exposition on my part calls for a presentation of the technical definition of "meme" from Lynch (1998):

"MEME: A memory item, or portion of an organism's neurally-stored information, identified using the abstraction system of the observer, whose instantiation depended critically on causation by prior instantiation of the same memory item in one or more other organisms' nervous systems. ('Sameness' of memory items is determined with respect to the above-mentioned abstraction system of the observer.)"

Removing the philosophy of science about abstractions (explained in the paper), this becomes more simply:

"MEME: A memory item, or portion of an organism's neurally-stored information, whose occurrence depended critically on causation by prior occurrence of the same memory item in one or more other organisms' nervous systems."

This definition identifies the minimum conditions needed to achieve the recursive process (or algorithm) that forms the basis of evolution by natural selection in interpersonally transmitted brain-stored information. It becomes the basis of transmission event diagrams and differential equations (Lynch 1998) useful in developing computer simulations of the meme transmission patterns discussed in the book *Thought Contagion*.

Filled as it is with misinformation about both the book *Thought Contagion* and the technical memetics paper cited in its preface, Marsden (1999b) fails spectacularly as a book review. What Marsden has "reviewed," is, in effect, his own series of misrepresentations. Those looking for fresh methods and topics in quantitative social simulation would therefore do better to ignore Marsden's contentious, misleading "review" and read *Thought Contagion* and its supporting technical papers directly.

SYNTACTIC STRUCTURE IN BIRDSONG: MEMETIC EVOLUTION OF SONGS OR GRAMMARS?

By

William Majoros

Celera Genomics

45 West Gude Drive

Rockville, MD 20850, USA.

Abstract

In order to ascertain whether the units of memetic transmission and recombination in the birdsong of a particular species of finch exist at the level of individual songs or instead at the level of grammar models, a large number of songs were subjected to grammar induction techniques and the resulting grammars analyzed for key structural properties considered indicative of the existence of an underlying grammar. The weight of evidence provided by this approach was judged by applying the same analyses to the results of a genetic algorithm applied to a synthetic repertoire of songs and comparing the results. Memetic evolution applied directly to song elements, as simulated by the genetic algorithm, was found to generate models very similar to those inferred from the House Finch song, thereby demonstrating that the problem of discerning between these two competing hypotheses for explaining the syntactic structure observed in House Finch song is not easily solved using the limited data obtainable in the field. This underscores the importance of experimental rigor when studying memetic systems, and leaves open the question of how to confidently determine the actual level at which memes are operating in a particular system.

Introduction

Beginning with an informal description of House Finch song and a brief review of the studies of that species' vocal behavior to date, we attempt to motivate the question of whether the units of memetic transmission and recombination in this species exist at the level of individual songs, or whether they may instead take a more abstract form, at the level of grammar rules restricting the allowable sequences of syllables within individual songs (section 1). We further point out that selective pressures for the evolutionary emergence of grammar models in bird song are entirely conceivable, based on arguments involving female preference and the advantages of data compression (section 2). We then describe the justification for the experimental technique employed in this study (section 3) and we describe that technique in detail (section 4). After presenting the results of the experiments (section 5), we attempt to interpret those results and provide motivation for further studies (section 6). This is followed by a brief conclusion (section 7).

1. Anecdotal Evidence for Syntactic Structure in House Finch Song

Much of the literature on bird song emphasizes the importance of individual songs, both in the production of acoustic behavior and in the transmission of cultural information via that behavior. Implicit in this song-oriented conception of avian vocal behavior is apparently an assumption

that the underlying representation for that behavior in the bird's brain is in fact some suitable neural encoding for the individual songs which can be produced by that bird; i.e., a simple time-ordered enumeration of the syllables comprising a song. This impression is given by the frequent use of the term "repertoire" by the authors in this field. The usual (but perhaps unfortunate) connotation of this term is of a set of songs each of which has been memorized in completeness and which is performed nearly identically every time.

It is reasonable to inquire, however, whether singing behavior may have a more algorithmic basis than the simple recitation of fixed songs. In particular, linguists have devised a standard hierarchy of so-called "grammars," called the Chomsky hierarchy [8], which classifies increasingly sophisticated methods for the generation of strings of symbols [note 1]. For species exhibiting considerable complexity in the structure of their songs, it is tempting to speculate on the possible existence of grammar-like mechanisms in their behavioral programming [note 2].

The House Finch (*Carpodacus mexicanus*) is clearly one of those species. Various authors have noted the complex and variable syntactic features of the song of this Fringillid. Munding [12] observed that in one region of his study area, "each male sang a wide variety of patterns, and individual variation in a given pattern was high." He also pointed out that "the precise mechanism of song learning in the wild is unknown" [note 3]. Bitterbaum and Baptista [1], working in California, noticed that "not only do no two birds sing exactly alike, but even a single bird seldom repeats himself precisely." Pytte [14] likewise observed in Wisconsin that "rarely is the same song repeated exactly" and concluded that "song types reported in this study appear to be largely an artificial construct."

Various authors have reported having the strong impression that many songs had been formed through the recombination of portions of other songs ([1, 14,16,18]). Tracy and Baker [18] speculate that "birds may be memorizing song components (syllables or phrases) that are strung together into complete songs at a later time" and Pytte [14], in relating the work of Bitterbaum and Baptista [1], explains that "juveniles learn individual syllables as units, which they segregate and recombine independently during song production."

However, these statements apparently refer only to subsong production by juveniles. As Lynch and Baker [10] stated more explicitly regarding recombination of song elements in the Chaffinch (*Fringilla coelebs*), "As song development proceeds, songs become less variable; by the time they reach 'crystallization,' they are highly stereotyped, and hybrid songs tend to disappear from the birds' repertoire."

Smith [16], on the other hand, offered the following intriguing proposal: "It is possible that house finches do not even choose songs or song elements, but choose a model(s) to imitate. Variation would then come from the 'mutations' of the model." Although he provides no further elaboration on the type of model that he has in mind, the fact that his work involves the construction of Markov chains from House Finch songs is highly suggestive; Markov chains are a simple form of grammar model [note 4]. However, Smith's models were inferred not from the songs of individual birds, but from the songs of all the birds in the local population in a given year, so it is not clear that these models are intended to describe anything other than the overall structure of the local dialect. Furthermore, the models were inferred in a highly subjective way; phrases do

not appear to have been selected systematically, and "hybrid" phrases were excluded from the model.

2. Evolutionary Advantages of Grammar-Based Song Generation

It is unfortunate that the hypothesis of grammar-based song generation has received only modest attention in the literature. In addition to providing a proximate explanation for the complexity observed in the song of some species, such models also suggest an ultimate explanation in those species where females have been shown to prefer males with larger repertoires; a grammar model with an appropriate cyclic structure can generate a potentially infinite number of distinct strings, though the model itself may have a fairly compact representation [note 6]. Thus, they provide a form of data compression, which natural selection may favor were such a mechanism to arise [20]. Such models also have interesting implications for the form and rate of cultural evolution in systems utilizing them, because the accurate induction of grammars from only positive example strings is known to be combinatorically difficult [4] [note 7].

3. Overview of the Experimental Approach

For the above reasons, I decided to apply grammar induction techniques to a large sample of House Finch song in order to investigate systematically the syntactic properties of this species' song, and to test the hypothesis that adult House Finches actually utilize such models while singing.

In order to test this hypothesis, I further posited that memetic evolution applied directly to songs represented as fixed syllable sequences would be incapable of generating certain statistical properties expected to occur in actual House Finch song. In particular, I posited that contingency tables constructed from pairs of states in the inferred grammar models would provide support for independence between the choices made at those pairs of states as the birds transitioned out of those respective states during song generation. Intuitively, one would not expect such independence to obtain in grammar models inferred from songs that had instead been generated via simple string recombination, because there is no obvious reason to expect random crossover between songs to respect phrase boundaries in such a way as to maintain the symmetry necessary for independence at pairs of states in the corresponding inferred grammar.

Although such independence may be expected to occur in extreme cases where extensive recombination has produced nearly all possible syllable combinations, such an extensive shuffling of syllables would seem to obliterate certain forms of order observed in actual House Finch song. For example, the models inferred in Smith [16], as well as unpublished analyses of data from Pytte [14] performed by myself reveal persistent multi-syllable themes that one would not expect to survive in the presence of high levels of random crossover.

4. Methods

4.1 Sound Recording

Recording took place between February 18th and July 12th, 1998, and was conducted in eighteen distinct suburban neighborhoods in Pennsylvania and Maryland, USA.

Recording equipment consisted of a 31-inch Telinga Pro Universal parabolic reflector fitted with a Sennheiser ME62 microphone, and a Marantz PMD222 portable cassette recorder. Songs were recorded onto Maxell high-bias (CrO₂) cassettes in the field and then digitized using 18-bit A/D conversion hardware and written to compact disk (CD-R).

Male House Finches were located by walking along a road and listening for song. When a singing finch was encountered, recording of that bird began immediately and continued until the bird ceased singing, the end of the current tape was reached, or another singing House Finch intruded upon the session. Thus, a single recording on the tape consisted of song from only one bird. Although the same bird may be represented in multiple recordings taken at a single site, this will not affect the grammar induction process, which was performed only within individual recordings.

4.2 Selection and Transcription of Recordings

Each session was indexed according to media location and recording quality. Quality values consisted of a subjective assessment of recording clarity, with an emphasis on the expected sonogram quality. The 263 recordings in the highest quality category were then selected for analysis.

Individual songs in the selected recordings were separated based on a subjective assessment of inter-song delay. House Finch songs are generally separated in time by a delay much longer than that between the individual syllables of a song (pers. obs.), so this process is largely unambiguous and replicable. Each song was stored in a separate file in ".wav" format. Recordings consisting of fewer than fifteen songs were omitted from the analysis.

Sonograms were produced using the Spectrogram 2.3 software [9] and printed out on a 1440 dpi photo-quality printer for manual analysis. Individual syllables were subjectively identified by spacing. Although a syllable often consisted of a single "trace" in the sonogram, some syllables consisted of multiple traces which were positioned very close together (in time) and which consistently occurred together in all sonograms. Thus, the process of separating syllables is rather more subjective than that of identifying individual songs, but a relatively high degree of reproducibility should be expected nonetheless.

Syllables were compiled into site-specific "alphabets," with a single alphabet being associated with all of the birds recorded at a single site. Each syllable was assigned a unique symbol, and songs were then translated into sequences of these symbols. These steps were all performed by a single person, in order to eliminate any inter-observer differences.

4.3 Grammar Induction

All of the songs produced by a single bird during a single, continuous recording session were used to infer a grammar model for that bird. The class of grammar model chosen for this study was the Moore machine, a type of finite automaton [8]. A Moore machine consists of a set of labeled states and transitions between those states, with the state labels prescribing the output of the machine upon entering that state. Moore machines are similar to hidden Markov models [3] except that there are no explicit transition probabilities, and each state has a label with an associated emission probability of 1 [note 5].

The first step in inferring a model was to identify common subsequences with which to label the states. This was accomplished by computing a multiple alignment between songs [note 8], using techniques developed for molecular biology. Beginning with the first pair of songs in the session, pairwise alignments were computed using the Needleman-Wunsch global alignment algorithm [3] between each successive song and the overall consensus sequence of the foregoing alignments, with individual syllables being treated as *residues* for the purpose of alignment. The alignment algorithm was parameterized as follows: gap open penalty = 1.5, gap extension penalty = 0.66, match score = 100, and mismatch penalty = 1000. This parameterization effectively precluded the alignment of nonidentical syllables [note 9].

Gaps in the alignment were used to infer breaks in the consensus sequence, with a break being established immediately left of the beginning of each gap and immediately right of the end of a gap. The consensus sequence was then segmented into the substrings delimited by these breaks, with an implicit break occurring at the beginning and end of the sequence. Each such substring was then assigned as the label of a state, with identically labeled states being merged into a single state.

Because of the manner in which breaks were inferred, songs could be unambiguously recoded as sequences of states, based on the positions of their constituent symbols in the multiple alignment relative to the breaks. These state sequences were then used to establish the state transitions by observing which states immediately followed which others in the recoded songs, much the way one goes about training a Markov chain [3]. Start states and final states were identified by their occurrence at the beginnings and ends of songs, respectively.

Grammar models were visualized using the daVinci program [19].

4.4 Contingency Table Analysis

A basic assumption of the class of grammar models employed is that the choice of transition made while in one state is independent of the choice of transition made in any subsequent state during the generation of a song. Complete failure of syntactic structure in House Finch song to exhibit any such independence would preclude generation of song according to this class of grammar models, but occasional violations of independence may indicate only that distinct states had been erroneously merged during the grammar induction process. Thus, the results of any independence tests that we apply must be interpreted within the wider context involving these imperfect model induction techniques.

In order to test for independence between the choices of transition made at pairs of states within individual songs, a contingency table was constructed for each such pair of states. In particular, for each pair of states $\langle X, Y \rangle$ such that Y follows X (potentially after some number of intervening states) in at least one song and such that both X and Y offer transitions to at least two successor states (fig. 1a), a 2×2 contingency table was constructed by tabulating the occurrences of the four combinations of transitions leaving X and Y ($\langle \text{left}, \text{left} \rangle$, $\langle \text{left}, \text{right} \rangle$, $\langle \text{right}, \text{left} \rangle$, $\langle \text{right}, \text{right} \rangle$) in all of the songs from the current recording session (i.e., for a single bird). In cases where more than two transitions left a state, all pairs of outgoing transitions from that state were considered separately, so that only 2×2 contingency tables were constructed. As an additional constraint on which of these state pairs would be considered, it was required that state Y be reachable from state X by at least two different paths.

Figure 1: (a) Contingency tables are naively assumed to arise from the depicted topology. Solid lines are transitions and broken lines indicate arbitrarily long paths. (b) A four-entry table could result from the merging of identically labeled states Y and Y' , but only if both have transitions to A and B . (c) A single-entry table could result from the merging of states Y , Y' , and Y'' , where Y' is a final state. (d) One form of two-entry table can be formed by merging Y and Y' . (e) Another form of two-entry table can be formed by merging X and X' . (f) Yet another form of two-entry table can be formed by merging Y and Y' in the topology shown. (g) A three-entry table can be formed by merging Y and Y' , but only if both have transitions to A .

Because it was supposed that a bird might perform a song several times in succession after generating it, and because my interest was in the generation of songs rather than their performance, any song which was identical to the song immediately preceding it in time was omitted from this part of the analysis.

Probabilities were assigned to contingency tables using the Fisher Exact Test [21] under the assumption of independence. Because a potentially large number N of such tests were to be conducted, an adjusted critical value was computed as follows:

$$1-(1-\alpha)^N=0.05,$$

or, equivalently,

$$\alpha = 1-0.95^{1/N}.$$

Using this computed α as the critical value sets the probability of committing at least one Type I error during the N tests to 5%.

Any particular statistically significant table is evidence only of a single instance of erroneous state-merging during model induction. A large number of significant tables would suggest that no state merging is appropriate, thereby seriously calling into question the applicability of this class of models. As previously mentioned, a small number of significant tables suggests only that the grammar induction algorithm commits occasional state-merging errors.

However, tables with four nonzero entries would seem to constitute positive evidence for the validity of this class of model, because a spurious four-entry table (regardless of P-value) would require not only erroneous state merging, but also the coincidental matching of transitions leaving such erroneously merged states (fig. 1b). Such a high level of coincidence is not required for the spurious generation of tables having one or more zero entries (fig. 1c-1g), with the possible exception of single-entry tables (fig. 1c). However, single-entry tables were deemed less informative than four-entry tables for the current application, because statistically nonsignificant single-entry tables tend to have very small entry sums, and they are therefore indicators primarily of inadequate sample size. Obviously, statistically significant tables with any number of nonzero entries were considered informative.

A large number of four-entry tables would therefore seem to be highly unlikely without the existence of an underlying grammar model of the type proposed, unless those tables were judged statistically significant by the Fisher Exact Test.

Unfortunately, the complexities of these grammar models make reliable estimation of probabilities for various types of grammar induction errors exceedingly difficult without adequate sample sizes. Because the number of possible paths through a model grows exponentially with the number of transitions, sample sizes obtained in practice can be expected to be woefully inadequate; therefore, a rigorous analytical treatment was not deemed practical.

My approach to compensating for this lack of rigor was to apply the same contingency table analysis to sets of simulated songs generated without the use of a grammar model (see below); any support for the existence of a grammar model obtained from this simulated data would nullify the value of any corresponding evidence found in the House Finch data.

4.5 Simulation of Memetic Evolution of Songs

In order to investigate whether memetic evolution applied directly to songs (rather than to grammar models) could generate syntactic structure similar to that observed in House Finch song, a steady-state genetic algorithm was applied to strings of artificial syllables. Genetic algorithms are described in detail in [6].

Briefly, an initial population of 14 to 25 strings of 13 to 24 unique symbols drawn from nonoverlapping alphabets was subjected to between 14 and 40 generations of panmictic and selectionless evolution. During each generation, 15 new strings were generated by applying two-point crossover to pairs of strings selected uniformly at random from the current population. Each new string then replaced an existing string at random. A two-point crossover operation combines the beginning and ending portion of one parent string with the middle portion of another parent string, to produce a new child string. The crossover points are selected at random. Note that differently-sized parents were allowed to recombine, and crossover points were allowed to vary between the two parents, thereby facilitating the creation of repetitive elements and further variation in string length. The final population at the end of each run was then subjected to the grammatical inference algorithm described above to infer a grammar model which was in turn subjected to contingency table analysis. Several thousand runs were performed under varying parameterizations until several grammar models were obtained which adequately matched those inferred from House Finch song according to various criteria.

In particular, the following quantities were required to differ by no more than one (sample) standard deviation from the expected values established by the House Finch data: number of states, number of transitions, transition density, mean state label length, mean in-degree, mean out-degree, number of start states, number of final states, number of cycles, mean cycle length, number of unique syllables, and mean song length. In-degree and out-degree are the numbers of transitions entering and leaving a state, respectively. Transition density is the proportion of combinatorically possible transitions realized. Cycles were identified by observing back-edges during a depth-first-search originating at each start state [2]; no attempt was made to identify composite cycles, so cycle sizes and counts are somewhat underestimated.

To summarize the intent of these experiments, my prediction was that four-entry contingency tables would be common in the House Finch data, with no more than a few of these being statistically significant, thereby demonstrating independence between transition choices made at different states during the generation of a song, and thus supporting the possibility that House Finches actually use some form of grammar model to generate their songs anew at each performance. In contrast, I predicted that the simulated data would produce either very few four-entry tables, or that most of these would be statistically significant, thereby supporting the intuition that syntactic structure of the type observed in House Finch songs would be highly

unlikely to occur by chance if House Finches were simply reciting fixed songs that changed only through transmission "errors" during cultural evolution.

4.6 Regression Analysis

Least-squares regression was used to fit a model of the form $y = mx + b$ to the number of transitions in a grammar as a function of the number of states. This analysis was applied to the grammar models induced from the field data and separately to those derived from the simulated data. Coefficients of determination (r^2) were computed to assess the quality of the regressed line, and t-tests were used to determine statistical significance. Regression analysis was performed using SPSS for Windows Release 8.0.0 [17]. Except where noted, all analyses were performed using unpublished software written by the author. Means are given \pm SD.

5. Results

5.1 Properties of House Finch Data

The 44 birds used for the analysis each sang 15 to 104 songs (mean 27.3 ± 19.4), for a total of 1,172 songs. Table 1 provides summary statistics for various other quantities. *State sequence length* refers to the length of a song when recoded as a sequence of states. Sample standard deviation is denoted by s.d. *Transition density* is the number of transitions divided by the total number possible in a complete graph. *In-degree* and *out-degree* are the numbers of transitions entering and leaving a state, respectively.

Variable	mean	s. d.	min	max
number of states	28.21	14.38	9	75
number of transitions	32.47	17.7	8	88
transition density	0.10	0.04	0.03	0.22
song length	14.64	4.91	4	47
state sequence length	9.23	4.03	1	34
state label length	1.89	1.62	1	13
number of songs per bird	27.3	19.4	15	104
unique syllables per bird	39.28	15.29	21	97
number of cycles	4.16	4.41	0	17
cycle length	5.22	4.82	1	21
number of start states	4.79	2.60	2	12
number of final states	10.30	4.03	4	21
in-degree	1.47	5.86	0	69
out-degree	1.47	1.02	0	7

Table 1: Summary statistics for House Finch data. Terms are defined in the text.

An example model inferred from the field data is shown in figure 2. There was considerable diversity in the overall structure of the topologies observed. In particular, not all of the models were long and narrow like that shown in figure 2, some had states with longer labels, and some had larger cycles than shown in the example.

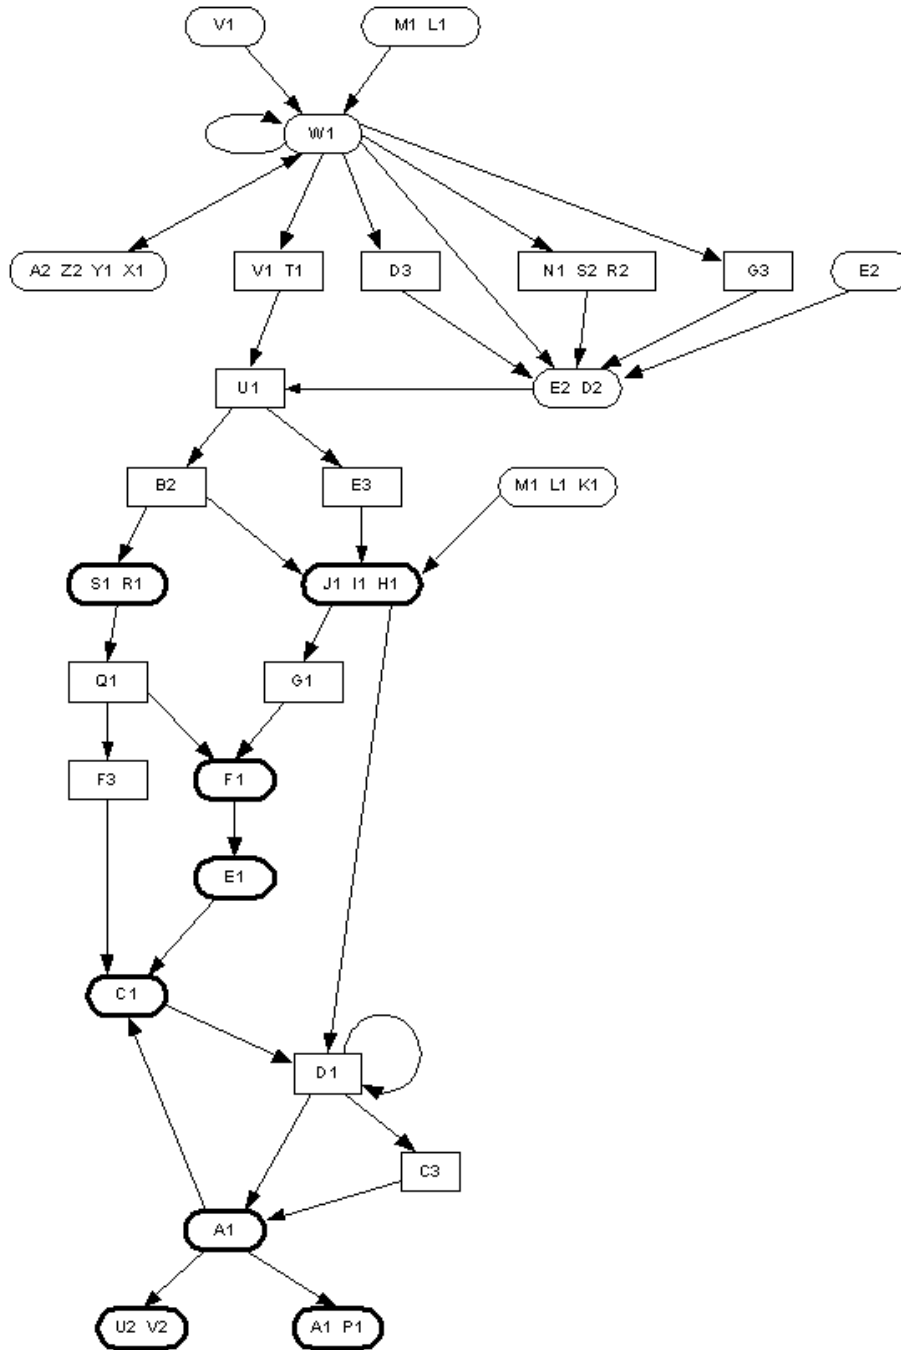

Figure 2: An example of a grammar model inferred from songs produced by a House Finch. Rectangles denote states, thin-lined ellipses denote start states, and thick-lined ellipses denote final states. Transitions between states are shown as directed arrows.

A total of 3,282 contingency tables were constructed from the inferred models. However, 3,176 of these (97%) contained two or more zero entries, and only four tables (0.12%) had four nonzero entries. These were:

1	1	1	1	31	13	25	12
1	3	2	1	1	2	3	2
P=0.53		P=0.60		P=0.207		P=0.35	

Of the 3,282 tables, only one (0.03%) had a P-value less than 0.05. This was:

0	12
5	3
P=0.0036	

However, due to the large number of tests conducted, an event with this probability could be expected to occur several times; the adjusted critical value given $N=3,282$ is 0.000016. Even if tables that extreme could not possibly be obtained with the given sample size, the fact that far fewer than 5% of the tables had a P-value of less than 0.05 supports the decision not to reject the assumption of independence.

The number of transitions in the inferred grammar models was found to vary linearly with the number of states ($m=1.22$, $b=-1.81$, $r^2=0.97$; $t=38.816$, $P<0.001$), as shown in figure 3. Because the number of transitions combinatorically possible between n states varies with n^2 , this linear relationship places appreciable constraints on the topological structure of the models.

Figure 3: Number of transitions (vertical axis) as a function of the number of states (horizontal axis) in grammar models inferred from House Finch songs.

5.2 Properties of Simulated Data

The models inferred from the simulated data appeared remarkably similar to those inferred from the House Finch songs. An example is shown in figure 4, which can be seen to be qualitatively like figure 2 in many respects. All of the relevant quantities for this run fell within one standard deviation of the mean values for the corresponding House Finch data, as shown in table 2.

Figure 4: An example of a grammar model inferred from simulated songs produced by a genetic algorithm.

Variable	field data	simulation
number of states	28.21	27
number of transitions	32.47	48
transition density	0.1	0.07
song length	14.64	13.79
state sequence length	9.23	11.50
state label length	1.89	1.35
number of songs per bird	27.3	14
unique syllables per bird	39.28	33
number of cycles	4.16	4
cycle length	5.22	1
number of start states	4.79	3
number of final states	10.3	7
in-degree	1.47	1.78
out-degree	1.47	1.78

Table 2: Results of an example run of the genetic algorithm.

This particular run produced a single four-entry contingency table:

A total of approximately 300,000 contingency tables were obtained during approximately 5,200 runs. Of these tables, 3,128 (1.04%) had four nonzero entries, and only 47 (0.02%) were significant at the 0.05 level. Thus, the simulations produced proportionally more four-entry tables and proportionally fewer statistically significant tables than analyses of the House Finch data.

As with the field data, the models inferred from simulated data exhibited a wider variety of topologies than can be communicated by a single example such as that given in figure 4. Like the House Finch songs, the simulated data gave rise to topologies with varying numbers and sizes of cycles, varying numbers of states and transitions, and clearly discernible variation in overall structure.

Table 3 gives the mean values of the previously-identified key quantities from a sample of 1000 runs. With the exception of the number of final states, all of the values are within one standard deviation of the mean values observed in the field data. Although this numeric agreement resulted from a conscious effort to match these quantities to the field data via refinement of the parameters to the genetic algorithm, the fact that such agreement could be achieved between these two systems is notable.

variable	field data	simulation
number of states	28.21	28.31
number of transitions	32.47	48.49
transition density	0.10	0.06
song length	14.64	15.04
state sequence length	9.23	12.92
state label length	1.89	1.32
number of songs per bird	27.30	19.63
unique syllables per bird	39.28	32.11
number of cycles	4.16	3.79
cycle length	5.22	1.58
number of start states	4.79	2.41
number of final states	10.30	4.85
in-degree	1.47	1.72
out-degree	1.47	1.72

Table 3: Mean results for 1000 runs of the genetic algorithm.

As with the field data, the number of transitions was found to vary linearly with the number of states ($m=1.57$, $b=4.19$, $r^2=0.75$; $t=17.240$, $P<0.001$), as shown in figure 5.

Figure 5: Number of transitions (vertical axis) as a function of the number of states (horizontal axis) in grammar models inferred from simulated data.

6. Discussion

Contrary to my predictions, simple string recombination was found to be capable of generating structures highly similar to those observed in House Finch song. Although considerable diversity was observed in both the models inferred from the field data and those inferred from the simulated data, suitable parameterizations were readily found for the genetic algorithm which would constrain various key measurements of structural complexity to within one standard deviation of the mean values obtained from the field data. Furthermore, the contingency table analysis failed to uncover more convincing evidence for transition independence in the House Finch data than in the simulated songs; indeed, the trend was in the opposite direction, with the genetic algorithm producing proportionally more four-entry tables (1.04% vs 0.12%) and proportionally fewer tables significant at the 0.05 level (0.02% vs. 0.03%) than the field data.

Lacking clear and compelling evidence for the existence of grammar rules in House Finch singing behavior, one might be tempted to invoke the principle of parsimony to establish rote memorization as the preferred hypothesis. However, it is not clear that either of the two hypotheses considered here (rote memorization vs. grammatically constrained improvisation) is significantly more parsimonious than the other. Although rote memorization would appear to be a simpler task than grammar induction, the potential for data compression afforded by a grammar model can lead to significantly greater space efficiency. Thus, while grammar models may be more complex in acquisition and operation, they are generally less complex in memory requirements and might therefore demand preference under a Minimum Description Length philosophy [15].

Thus, the question of whether House Finches generate their song using some form of grammar model remains unanswered, and it is questionable whether data collected in the field can definitively resolve the issue. What is likely needed is a set of controlled laboratory experiments, where large samples can be obtained from each bird and where training material can be specifically designed to create various informative testing scenarios.

An important point which has heretofore not been emphasized is that the hypothesis being considered is not simply that House Finches utilize some grammar model in generating their song, but that they specifically adopt a model which accounts for patterns that they identify in training songs. Thus, it is conceivable that controlled experiments might be designed which were capable of detecting a bird's ability to identify and recreate syntactic structures in the songs of an artificial tutor. The task is essentially one of distinguishing between concept learning versus rote memorization in a complex adaptive system.

Failure to foresee the results of the memetic simulation is perhaps attributable to the interaction between the shuffling effects of random crossover and the propensity of sampling error to create spurious order. The same susceptibility can be expected whenever a grammar induction algorithm is applied to moderately sized samples. Even for a collection of strings known to have been generated using a grammar model, one should not expect a black-box algorithm to reconstruct that model with complete accuracy in even the majority of cases. Not only are sample sizes generally limited in practice by the difficulties of working in the field, but grammar

induction algorithms are truly only heuristics, and are guaranteed to correctly reconstruct the original grammar only under special circumstances ([4, 5, 13]), which may not obtain in practice. If it can be demonstrated that House Finches do indeed employ syntax rules in the generation of their song, then a next step would be to characterize the range of complexity possible in those rules. This would require analysis of bird song from a diverse range of geographical locations, because the structural properties of song recorded in one locale can be highly sensitive to the evolutionary history of the local song tradition. That significantly different conclusions could be drawn from different populations of House Finches can be clearly seen by comparing the results of research conducted in different regions of the U.S. (Mundinger [12] in New York and Connecticut, Bitterbaum and Baptista [1] in California, Pytte [14] in Wisconsin, and Tracy and Baker [18] in Colorado).

Alternatively, if direct song recombination is ultimately established as the mechanism behind the evolution of, and apparent order observed, in House Finch song, then it is conceivable that syntax analyses may still be useful in elucidating some of the parameters of that evolutionary process. Furthermore, the recombination mechanism need not be as simple as the two-point crossover approach used here. The details of this recombination remain to be determined. All of this would require large-scale analyses.

There does not appear to be any logical way to distinguish between the use of grammar models by juveniles which later crystallize their song into fixed syllable strings versus the direct use of syntax rules by singing adults without resorting to invasive techniques such as neuronal monitoring of singing birds, and it is doubtful that current technology and neuroanatomical knowledge are adequate for such an undertaking [11].

Finally, Lynch and Baker [10] predicted that a "general theory of cultural evolution in bird song" would eventually emerge. Before this can happen, the actual nature of memes in bird song must be determined. Lynch and Baker [10] defined memes as syllables and sequences of syllables, but they did not consider higher-level structural elements, such as state transitions or syntax rules. Only a greater understanding of bird song generation will determine whether such extensions to their quantitative theory of cultural evolution are necessary. As stated recently by Greene [7], "We currently lack a coherent conceptual model that explains the diversity of singing behavior and song learning programs in an evolutionary framework."

7. Conclusion

Statistical analyses were conducted to test the hypothesis that House Finches generate their song using a simple form of grammar model similar to a hidden Markov model. Results failed to convincingly show that such models are necessary to explain the syntactic structure observed in House Finch song. However, it was argued that this hypothesis cannot be dismissed simply on the grounds of parsimony.

Although song-centric models are perhaps the most natural and convenient way for human researchers to conceptualize vocal behavior in birds, until we have a more thorough understanding of song learning and performance in species having complex song, more sophisticated models of song structure such as those considered here should be viewed as valid

avenues of investigation. Given the potential complexity of these models, addressing such important issues as the selective advantage they confer, their impact on the form and rate of cultural evolution, and the bias they exert on observed syntactic structure in bird song should make for challenging and fascinating topics of future research.

Acknowledgments

Carolyn Pytte kindly provided sequence data for preliminary analyses which inspired this study, and provided copies of several relevant papers. Mark Yandell and Daniel Edelstein provided valuable comments on a previous version of the manuscript, as did the anonymous reviewers; I am indebted to them all for their suggested improvements.

Notes

Grammar models generally consist of an *alphabet* of symbols and a mathematical construct specifying the way in which those symbols can be combined to generate *strings*, or finite symbol sequences. For birdsong, we can take the individual syllables comprising a song to be the symbols and the entire song to be the generated string. Two prominent classes of grammars in the Chomsky hierarchy are the *regular grammars* and the *context-free grammars*. Context-free grammars are the more powerful of the two, and involve the use of *productions*, or *rewrite rules* (such as "X can be replaced by ABC") that may be recursively applied to transform an initial string of variables into the final observed form of the string. Context-free grammars are in general implicated in processes that generate matching pairs of symbols, and palindrome-like patterns. Regular grammars, which constitute a proper (and less powerful) subset of the context-free grammars, are equivalent in their computing power both to *regular expressions* and *finite automata* (also called *finite state machines*), which consist of *states* and *transitions*, and which are often depicted as small circles with arrows connecting them into allowable paths.

This is in no way meant to imply, however, that all, or even most, bird species utilize grammars for song generation. Many species have song which is too simple or too stereotyped to suggest utilization of a grammatically-constrained, stochastic song generation procedure. On the other hand, it is not unreasonable to consider grammar-like mechanisms that may be at play as songs change over evolutionary time, or to consider the use of grammatical theories to describe the syntactic structure of songs produced by birds which are not themselves using grammars to generate their song. However, this work is concerned only with the possible use by birds (House Finches in particular) of grammar models during singing behavior.

Mundinger [12] refers to an unpublished manuscript that deals with song learning in this species, but the manuscript in question actually describes experiments involving the training of House Finches in the laboratory by another species of bird [pers. communication], and I know of no other work to date that examines song learning in this species, either in a controlled setting or in the wild.

Markov chains and hidden Markov models (*HMM's*) are generalized forms of stochastic finite automata which provide explicit *transition probabilities* and (in the case of HMM's) *emission probabilities*. The model begins in the start state and moves at random from state to state, according to the transition probabilities, emitting a symbol or string of symbols upon entering each state, until a final state is reached. In this way, the model generates a string consisting of the concatenated symbols emitted by the states that were visited during operation of the model. In HMM's, the emission probabilities of a state determine what symbol is emitted when that state is entered, whereas in a Markov chain, there is only one choice of symbol for each state, and the symbols labeling different states are unique.

A Moore machine operates much like a Markov chain. The machine starts out in one designated *start state*, transitions stochastically from state to state according to the allowable transitions, and emits the symbol or string of symbols labeling each state when that state is entered. The computation can end only when the machine is in one of the designated *final states* (although transitions out of final states are permitted), and the result of the computation is taken to be the concatenated labels of the states visited during operation of the machine.

In general, the more compact models tend to generate larger, less constrained, sets of strings, so if natural selection were to favor either higher-entropy signals or more compact models, one might expect the ultimate outcome to be a species which generates its song by simply emitting syllables entirely at random, without following any grammatical constraints. However, other selective pressures operating simultaneously may prevent the reaching of this extreme condition (as may lack of evolutionary time or insufficient genetic variation), so it is not unreasonable to expect that we may observe a species producing grammatically-constrained song.

This assumes, of course, that the grammars are learned rather than innate. There are certainly species for which this is not a good assumption, as mentioned above in note 2.

An alignment between two strings of symbols, or *residues*, is a representation that explicitly shows the subsequences common to both strings. Short runs of spaces, or gaps, may be inserted into one or both sequences in order to shift portions of the sequence to the left or right in order to maximize the number of matching symbols which are aligned between the two strings and minimize the number of nonmatching symbols which are aligned. A *multiple alignment* is an alignment between three or more strings, whereas a *pairwise alignment* includes only two strings.

The Needleman-Wunsch algorithm utilizes a dynamic programming approach to pairwise alignment by filling in an alignment matrix indicating the cumulative scores of all the different possible partial alignments up to the current position in the two strings. By specifying different parameters, such as the *gap open penalty* or the *mismatch penalty*, one can adjust the behavior of the algorithm in various ways to suit the task at hand. Although the Needleman-Wunsch algorithm computes only pairwise alignments, it can be used iteratively to incorporate another sequence into an existing alignment, thereby producing a multiple alignment. This is similar to the popular CLUSTALW program, which first computes a *guide tree* in order to determine the order in which the pairwise alignments should be performed. Although a guide tree was not used

in this study, future work may wish to do so, in order to account for evolutionary relationships between the strings to be aligned.

DAWKINS BAD IDEA: MEMES, GENES, AND THE METAPHORS OF PSYCHOLOGY

By

P.O. Box 29445, New Orleans, La. 70160

Lanna@bellsouth.net; and drmezmer.com

In times past, if the devil didn't get you, the vapors would, and if they didn't, humours, poisons, bile or any number of fanciful entities would do you in. With Pasteur and 19th century biology, these agents of illness were replaced with microscopic organisms, and the invention of the disease model made it easy to attribute your aches and pains to malicious bacteria, viruses, or other little microscopic buggers. Of course, then as now, few people understand the actual biological processes that are responsible for disease, but the *metaphors* for disease do just fine, and have been duly incorporated into the common vernacular. Some may say that these metaphors have worked a bit too well, since they have made a Procrustean stretch to cover all sorts of behaviors, from alcoholism to gambling. Nonetheless, the incorporation of metaphors from the syntax of science does provide a correcting influence to common sense, which earlier had only recourse to metaphors that engaged evil spirits and deadly vapors to help explain the world.

Nowadays, man has access to a wealth of metaphors from modern science. Cancers, black holes, laser beams, and computer viruses have replaced the vitalistic metaphors that assigned causes to ethereal spirits, evil demons, or invisible ethers. Of course, the incorporation of the metaphors of the biological and physical sciences into common language does not entail the ability to map actual processes, but only *suggest* those processes. The metaphorical description of a cold and its viral causes does not equate with a biochemical or biological description that requires a strict syntax and data language all its own. Thus when we mix our metaphors by talking about rampaging viruses spreading like wildfire from person to person, we know that our description only suggests what viruses are doing in the large, not the actual processes that cause them to propagate and harm.

The mixing of metaphors from different data languages can be poetic insofar as it suggests the juxtaposition or correlation of causes and events, or it can be interpreted as *literal* insofar as it presumed to denote actual processes. But how do we know if 'rampaging viruses' are a literal or a figurative representation of the truth? The ability in science to distinguish the literal from the alliterative is the mark of good science, and good science writing. A physicist may talk about matter using the metaphors of billiard balls, time warps, and cosmic string, but the literalness of those concepts is intentionally undermined by a continuous restatement of the mathematical metaphors that belie their literal reality. So why does a physicist engage two sets of metaphors when he can participate in his science quite well without the need to postulate billiard ball atoms and the like? It is simply because 'understanding' requires it. On the one hand, common sense metaphors are easily understood through their appeal to conceptual domains that we readily perceive (e.g. up, down, fast, slow, hot, cold), but mathematical metaphors (e.g. $E=mc^2$) correct

for the tendency to make their existence literal. Well-written books that popularize ‘hard’ physical science all recognize the necessity to utilize two different sets of metaphors that correct the deficiencies of the other. Thus an understanding of the physical world can engage metaphors that are derived from our native experience and those that are derived from the abstract language of mathematics. Understanding consists in our ability to move from one set of conceptual metaphors (e.g. green grass, hot suns, and expanding universes) to another (e.g. the calculus, non-Euclidean geometry). It is no less than our ability to shift between different languages that enables us to envision the world.

Sometimes however, two entirely different sets of conceptual metaphors may be quite similar in terms of the processes they describe, and proceed to confirm rather than contrast with one another. Newtonian ideas of acceleration, mass, gravity, force, etc. have long been assimilated into our popular lexicon because a Newtonian view of the universe coheres with our own naïve experience. The mechanical universe of Newton corresponds with common sense theories of the physics of cars, boats, apples, and other physical objects, and is much easier to understand and accept than other more accurate physical theories that are reflected in the conceptual metaphors of Einsteinian relativity and Quantum theory. However, the conceptual metaphors associated with relativity and the invisible quantum correct for the literal interpretation of Newtonian mechanics as a representation of reality, and have entailments (e.g. time travel, multiple universes, quantum indeterminacy) that are dramatically at odds with the Newtonian conception of a clockwork universe.

In the biological sciences, the Darwinian principles of natural selection have an import comparable to Newton, and the conceptual metaphors of evolution find an equal correspondence with common sense theories of human psychology. Common sense or ‘folk’ theories of psychology tell us that we are motivated by ordinary objects (e.g. cars, jewelry, money, sex) whose value we determine consciously, and either impel (as in eliciting drives and reflexes) or compel (as in rewards, reinforcers, or punishers) behavior. In a Newtonian sense, our lives revolve around the collection of ordinary objects that push and pull us to them from a distance, and populate but scarcely our psychological universe.

This common sense explanation of how behavior is selected bridges quite easily to conceptual metaphors that describe how biological entities are selected, and by implication to the behavior that is instantiated by those entities. Thus patterns of behavior that are elicited by instinctive events can be ultimately attributed to individual genetic influences that are objectified in the metaphors of the activities of individual genes. Similarly, the common sense notion that ideas are selected by some obscure competition between objective alternatives also finds an equal bridge to selectionist principles that are derived from biology. Thus, just as Newtonian physics and common sense physics seem to confirm each other, common sense psychology and Darwinian biology share similar metaphorical principles that explain respectively how behavioral and biological selections are made.

As with the blending of metaphors that saw the adoption of Newtonian terms into common sense physics, metaphors from biology and ‘folk’ psychology have also become commingled, and thus form a new explanatory framework for behavior that explains behavior as a Darwinian process. Thus genes become ‘selfish’, and ideas or memes become ‘contagious’. But these are only two

different levels of thinking, and do not implicate the metaphorical schemes that explain the actual neurological processes that underlie behavior.

Darwinian or sociobiological explanations strongly imply that the molar processes of cumulative selection that led to bumblebees and human beings are isomorphic with neural or 'molecular' processes of the mind that lead to the selection of behavior. But an implication is *not* a demonstration, as a sociobiological explanation merely establishes a similarity between the *metaphors* of common sense and natural selection. The overriding question is not whether genes and memes represent a good metaphorical bridge between common sense and biological explanations for behavior, but whether they provide an equally good metaphorical representation of the *biobehavioral* processes that instigate behavior. The question is analogous to that posed by Quantum physicists to the common sense and academic views that extended the metaphors of Newtonian physics to the molecular world of the atom. The answer to that question was not a reaffirmation of the perspective of atoms as mere baby solar systems, but of the creation of an entirely new science that was equally rooted in the empirical tradition of science. That science was quantum physics.

A biobehavioral explanation of behavior represents the mapping of the actual neurological processes that comprise behavior to the patterns of information or environmental contingencies that parallel and elicit them (Donahoe and Palmer, 1993). This information is in turn mediated by somatic events that are perceived as emotion (Damasio, 1996), activating neurological events that comprise attentional processes (Donahoe and Palmer, 1993), and nativistic (i.e. inborn or genetic) sensitivities to certain abstract patterns of information (Bolles, 1976). Whereas a biobehavioral explanation is neurally realistic because it ties behavior to actual neural and informative events, a sociobiological explanation is neurally unrealistic, and merely substitutes neurological processes with Darwinian metaphors.

Biobehavioral science, which is also known as 2nd generation cognitive science (Lakoff, 1999), or theoretical behaviorism (Staddon, 1990), is, like evolutionary psychology, entirely informed by evolutionary principles. However, it is more rigorously empirical because of its insistence on ultimately observing or reliably inferring the neural processes that intervene between information and behavior. Biobehavioral and evolutionary psychology are represented by entirely different sets of conceptual metaphors that are respectively entailed by molecular (small scale processes and time frames) and molar (large scale processes and time frames) processes. The polarity of these metaphors is remarkable, and can be reduced to the following contrasting principles. Evolutionary psychology and folk psychology share the implicit presumption that decision making is generally based on the conscious and disembodied appraisal of ordinary objects that lead to the maximization of our self interest. In contrast, biobehavioral psychology has demonstrated that most reasoning is not conscious but nonconscious (Lewicki, 1992; Greenwald, 1992), and is guided by embodied non-verbalized somatic (Damasio, 1994) and neural activation events (Donahoe and Palmer, 1997) that are 'just as cognitive as any other perceptual image' (Damasio, 1994). Because nonconscious embodied reasoning is computable but not directly accessible by conscious reasoning, we often find that our conscious reasoning about what is a 'best outcome' conflicts with our nonconscious determination of 'best outcome'. Thus there is no univocal or self-consistent locus of value (Lakoff and Johnson, 1999). (Remember this next time you reluctantly try to get up in the morning.) Values are due to the binding of many information

streams that are mediated by disparate neural and somatic processes, and motivate behavior in real time as they are perceived, and not when the physical or objective entity that denotes such information is attained. (In other words, it's the thought that counts) Thus value is not found in some conceptual object like a meme, but in separate threads of information that are mediated by the mind and body that individually have salience to an individual and are perceived presently, independently, virtually, and for the most part nonconsciously. In other words, the concept of ideas as compartmentalized memes leads us to find value in the obvious topographical or 'surface' aspects of an idea, whereas it is the non-obvious abstract properties that are actually selected. Because value resides in information that is often incognizant to us, it cannot be subject to the economic models that are based on the rationing of value according to some single utilitarian measure, or the mathematical decision models such as game theory that conceptualize value simplistically as being no more than material wealth.

The definition of a meme as an independent conceptual object is ultimately not simple, but simplistic, since it does not denote the web of informative relationships between behavior and the environment that is denoted by consciously and nonconsciously by the mind and body proper. For example, the concept of the sport of football is a well traveled meme to be sure.

Football represents a rather involved information pattern that has infected the minds of young men nationwide, and football games, commentary, and assorted chatter has parasitized not only the minds of people, but the network airwaves, the written media, and many unwilling housewives. But is a football game an indivisible meme like entity, or is it somewhat different than the sum of its parts? Actually, the 'meme' of football is not a singular information pattern that replicates like a strand of DNA, but rather emerges from a web of separate patterns of information that are mediated not only by consciously perceived information but by neural and somatic activating processes that we otherwise call emotion. The meme of football is not just a compendium of rules, but comprises the memory of the somatic responses that occur while watching (excitement, depression), the natural feeling of elation that occurs with a high state of alertness, the virtual extension of control over all those partisans of the losing team, the constantly changing and stimulating prediction error that occurs as one play after another unfolds, the smell and taste of hot dogs and beer, the camaraderie of friends, and so on. The meme of football is in other words a web of perceptual relationships that is volatile and constantly changing. Moreover, different aspects of the meme football may be present in one circumstance, and not present in another. Watching your team lose at a hostile stadium on a rainy day is a whole lot less rewarding than if you were watching your team at home while among friends. And what is a meme when it becomes frayed around the edges?

The most important distinction contrast between evolutionary psychology and bio-behavioral psychology is that bio-behavioral psychology denotes value not in the assimilation of ideas or memes, but in changes in the *relationships* between memes, or behavioral discrepancies (Donahoe and Palmer, 1993). To explain this, we must understand first how a meme does *not* reproduce. Although a meme represents a self replicating packet of information, unlike a virus it possesses no internal instructions that secure its influence on behavior, let alone its retention in memory. Memes or ideas take root in memory because they are rehearsed, and they are rehearsed because of their contingent relationship to a myriad other ideas that comprise the stimulus context of a behavior. This idea of contingency is critical to the methodology of modern

behaviorism, and underlines the fact that it is not ideas alone that motivate, but the dependencies between ideas. The meme of a fishhook for example hardly comes to mind until it is perceived as part of a means-end (memes-end?) expectancy. We think of fish hooks because of the fish it can catch, but to even think about fishing one must also think about the time, place, and equipment that allows one to fish. If any of these events fail to take place, there is hardly a need to think about fishing, or for that matter the meme of fishhooks. An atomized universe of memes does not implicate the contingent relationship between ideas that secures the rehearsal and retention of a 'good idea'. Behavior is elicited not by individual memes but by global maps of means-end expectancies that are constantly changing, and are in general non-consciously perceived.

However, what causes us to think about fishhooks, fishing trips or other ideas is the fact the relationships they denote are selected and are mentally rehearsed. We constantly think about a fishhook as it winds its way from our tackle box to the end of our fishing line because in every moment the relationship between the fishhook and the line changes, and it is the change that gains our attention. Thus, we select not only memes, but also the abstract *relationships* between memes as they are moderated by our thoughts and overt behavior. Ultimately, as Alexander the Great found out when he wept upon having no more new worlds to conquer, what motivates is not the end, but in the traveling.

Unfortunately, Darwinian and common sense models can no more describe the molecular 'environment-behavior' relationships that comprise human motivation than a weatherman's description of an impending cold front describes how a snow storm forms over your head. We would err in using a molar analysis (cold fronts) to describe molecular process (the formation of clouds) because the inherent processes implied by storm systems and storm clouds are different. Likewise, the human brain is a massively parallel biological computer, and metaphors from information processing are far more apt than biological metaphors that liken ideas to viruses and their spread to contagion, let alone the metaphors from common sense that posit a disembodied objectified reasoning. The lack of 'fit' of Darwinian and common sense metaphors to bio-behavioral science does not invalidate the selectionist principles that inform all of the sciences. But it does point out the level confusion that occurs when a set of principles from one level of understanding (biology) are invoked not just to explain another (an in the juxtaposition of the metaphors of cosmic string and mathematics) but to *embody* another. In other words, because the uses of memes and genes is not corrected by an understanding of how the brain as a neural system actually works, the metaphorical conception of memes and genes can easily be seen as not just figuratively real, but literally real.

The ultimate danger in assigning a literal reality to the means-end rationality imposed by utilitarian memes and genes is that it implies that we implicitly know what is in our best interest. Furthermore the convergence of the metaphors of common sense and Darwinism reinforce the idea that value is objectified and is a limited commodity, and must be allocated to those who are most fit to achieve it. In this way, a meme world becomes 'mean' world, wherein our memetic impulses robotically drive us forward to achieve our goals, with the long term survival of our genes and memes being the only necessary outcome.

In contrast to this cold and sterile vision, bio-behavioral psychology defines value not as a scarce commodity, but in the creation of information that is consumed virtually. That is, if value is

denoted in abstract informative relationships between ideas, then it is prospectively unlimited, and is constrained not by our inability to manufacture physical things, but by our ability to create and perceive information. But perception requires the skills that enable us to mentally model the world, from the implications of the cheers of a crowd in a football game to the thoughts of a proud parent. To experience the world is to model it, and that is nothing more than empathy. Universal empathy allows us to expand and enhance the rewards we perceive, but it also constrains our behavior due to the virtual penalties (e.g. shame, embarrassment) we perceive.

Cultures that understand that value derives from the development of empathy will take an entirely different course than the materialistic societies that posit value as the accumulation of objects. Indeed, information is more economically produced by a societal exaltation of sports, art, literature and music than by the manufacture of a new prestige automobile. Ironically, the lasting legacy of a psychology that is informed by evolutionary principles is not the amoral world driven by the erroneous metaphors of selfish genes and infectious memes, but by the evolutionary mandate of an expanding empathy, and our innate interest in the cultivation of beauty.

(The best introduction to bio-behaviorism comes from Shull's article on the website of the Journal for the Experimental Analysis of Behavior, and the scholarly commentary also at the JEAB website that discussed this new school of behaviorism. An understanding of metaphor and how it heavily influences ideas in evolutionary psychology can be found on the many web sites that discuss the work of the cognitive linguist George Lakoff, and in particular his new book: *Philosophy in the Flesh: The Embodied Mind and its challenge to Western Thought*)... and of course there is my own site, drmezmer.com, which is pure irony.)

CRASH CONTAGION

Abstract

Using a memetic interpretation of the events following the death of Diana, this paper introduces memetics, by way of example, to social scientists and social researchers. It is argued that standard social scientific interpretations of human behaviour are overly rational and may ultimately be quite unhelpful in understanding human behaviour. The paper explores the possibility that memetics may provide researchers with a viable non-Cartesian conceptualisation of the human individual and behaviour. Substantively, the paper argues that much human behaviour may be a product of non-rational imitation and suggests that such an interpretation may help explain the mass hysteria following the death of Diana, Princess of Wales.

"It gives you a scare. Initially it just looks like a white mass."

"A shiver went down my spine. It was Di... Seriously top right hand corner. It's just there"

"Princess Diana's face is looking out of it. Everybody's seeing her face looking out"

"We saw it, as clear as day. You know the pose, the one with her head cupped in her hands. She's got the tiara on"

These people are referring, of course, to the visions of Diana that appeared to mourners waiting patiently in line to sign one of the Books of Remembrance at St James Palace in September 1997. A vision, we were told by these tearful mourners, that was a copy-conform of Diana's Vogue cover pose. The visions started the same day, in the middle of the planetary Diana'thon, that an Iraqi newspaper, the Babel, reported that Princess Diana had been assassinated by the British secret service.

Di' mentia had seized the world's press. The morning following Diana's death, the Observer newspaper didn't have time to cancel the article on Diana which concluded that "if her IQ were five points lower (she) would have to be watered daily". The Sunday Mirror which following her death was creased with grief had just a few weeks earlier described Diana as "trivial and brain-dead". But the accident changed all that.

From Sunday morning, news-readers, sounding increasingly like narrators of a badly written romantic tragedy, delivered hour upon hour of repetitive commentary, only punctuated from time to time by solemn, ashen-faced "experts" who would advise us "grieve in our own way" the death of this, the People's Princess.

The media may have been suffering from Di'mentia, but the world was suffering from Di'mania. The deification and the arguments for canonising the icon Diana began well before the visions. With Diana's death, a cult has been born; a secular saint had been created by popular acclamation. Britain's own Mother Theresa Lite, with the option on good legs included, was perfectly packaged for the age of the video-clip and the sound-bite. "The Queen of Hearts" became "the light of our life", "a candle in the wind" who possessed, as a member of the British House of Lords confirmed, a "genuine gift of healing".

Saturday 6th September 1997 was a world first; half of the human inhabitants of Planet Earth were wired up and tuned in to witness the most widely experienced event in our history. The funeral of Diana, Princess of Wales. The funeral was broadcast live to over 60 countries in 44 languages with an estimated audience of 2.5 billion people.

Television stations dropped their scheduled programmes and replaced them with tributes to Diana. Pop radio stations decided that pop music was inappropriate, some stopped broadcasting altogether whilst others threw themselves into weeklong session of mournful "sombre music only..." One London radio station even offered free counselling to those in distress. The event temporally but fundamentally modified peoples' behaviour. Elton John even took out his earrings, and the Union Jack was flown at half mast over Buckingham Palace for the first time. Millions of people converged on London for Diana's funeral, more people were present than had been at the celebrations in London at the end of the Second World War.

It is our interpretation, as social scientists, to the reaction to the death of Diana that I would like to pause for a few minutes and reflect upon. Now, one obvious line of social scientific enquiry would be to try to provide an account of why people responded in such a way to the death of Diana. We could explain their behaviour by referring to notions of self and identity, to internal states, to attitudes and dispositions. We could interpret the mass mourning as an example of how our inner human selves can sometimes break out of the iron cage of rationality in an alienating capitalist (post) modernity. We could look for the real, true and underlying reasons for the Diana phenomena interpreting it from within one of the plethora of theoretical paradigms that we as social scientists have at our disposition.

To take a brief example of how we can use inner states to explain our behaviour to the Diana phenomenon, I want to concentrate just on our immediate reaction to the news of her death. Clairvoyance and other X-Files-type phenomena aside, the death of Diana must have been temporally antecedent to our reaction to it. For each one of us, there must have been one fascinating moment between the time that the patterns of information reporting the death of Diana entered our heads and the time that we reacted or responded to the news. That fascinating moment was the moment when the electrochemical signal travelling up the axons of neurons in our heads became conscious thought. Cartesian psychology would have that in some dark corner of our brains where consciousness presumably 'happens', the signals were translated into the language of thought, a sort of '*mentalese*', and were then projected as subjectively meaningful internal representations in our heads, to a special audience - the conscious self. (That same conscious self that "sees" the image of Diana when you shut your eyes and imagine her.) The incoming signal became conscious experience and we finally realised that Diana is dead. In this way, we, *ourselves*, the real, conscious selves, could then evaluate this shocking new fact from

the control centre of the mind and send out instructions to our bodies and brains about how to react to it. And just how did we react to the news when we became conscious of it?

Some of you may have responded with emotional upset, some of you even may have taken your earrings out as well, whilst others may have just carried on eating breakfast. Your reactions will have been rich and varied, fascinating stuff for social scientists, but I am willing to bet that all of you, every single one here today, reacted identically in one very special way. Despite our preciously individual inner selves, I suspect you all reacted in a slavish, machine-like fashion to the news of Diana's death with a response that doesn't need the Cartesian crutch of that inner self to explain it.

You just had to talk about it. You had to communicate the news in some way or another to someone else. You may have phoned somebody in order to talk to them about it, or the subject may have come up in conversation at a later time, but the information that you received got itself passed on, copying itself, infecting another brain. It was almost as if the words in your head wanted to get themselves said, rather as if your mind had been infected with a virus, much like a flu virus, which in spite of yourself, spread themselves in a fit of verbal sneezing.

I think there is an alternative to positing homunculi, mysterious internal agents or selves endowed with all sorts of intentional, evaluative and emotional capacities in our brains to explain the Diana phenomenon. In any case, these sort of 'explanations' don't really explain anything at all, they just take us down the tedious road of infinite regress: If you argue that we can evaluate information, and respond intentionally because we have selves, then how is that selves come to be intentional and have rational capacities in the first place? If our selves are looking on in the inner theatre of consciousness, who is looking in on their inner theatre consciousness? Do our selves have their own selves?

No, our reaction to the death of Diana does not need the theoretical and often circular crutch of the self. I think we need to understand our reaction as a symptom of having been infected with a virus; a mind virus. The death of Diana can be explained by the epidemiology of a contagion, a crash contagion that leapt from mind to mind infecting new brains. A virtual virus that hijacked the copying machinery in our brains to copy itself onto other brains through a process of communication. In this way the crash contagion spread through the population through a process of replication in a global game of Chinese Whispers, as if it was a virus.

Our behaviour following the death of Diana owes much more to epidemiology than it does to the reaction of some inner self. Just as virtual pets, Gameboys and Rubik's Cubes sweep through, and leap between, schools in a manner virtually identical to measles or chicken pox, so did the Diana Crash Contagion. Whether the symptoms are spots, sneezes or the fixed motor behaviours associated with feeding your virtual pet or reacting to the news of Diana's death, we need epidemiology and not internal agents to explain our behaviour.

A key issue in the spread of the Diana crash contagion was the role of the mass media as a vector. More generally, the mass media has been responsible for an explosive proliferation of all sorts of mind viruses that exist in today's infosphere spread via radio, television, the press, intranets, internets, fax machines, e-mail and voice mail. Every year, your brain is assaulted by

thousands of designer mind viruses trying to infect you in the form of advertisements. Our minds today are suffering from a chronic case of information overload, our brains are clogged up by virtual parasites, mind viruses that spread around the world at the speed of light, replicating at rates that make AIDS and meningitis appear quite unthreatening in comparison. And mind viruses can be just as deadly as their biological cousins, leaping promiscuously from vehicle to vehicle, and from medium to medium, coding for all sorts of behaviour, whilst proving to be virtually unquarantinable (Dennett 1990).

The study of mind viruses is known as memetics, and the unit of replication, the mind virus is called a meme. The term was coined by Richard Dawkins, author of *The Selfish Gene*, a successful popularisation of a gene-centred Darwinian understanding of evolution. In addition to his now familiar metaphor of the human body as a gene-machine, Dawkins argued that we were hosts not to just to one replicating entity (the gene) but also another, virtual mind viruses that he called memes.

"A meme is a unit of cultural transmission, or a unit of imitation. 'Mimeme' comes from a suitable Greek root, but I want a monosyllable that sounds a bit like 'gene' . . . it could alternatively be thought of as being related to 'memory' or to the French word *même*. . . Examples of memes are tunes, ideas, catch-phrases, clothes fashions, ways of making pots or of building arches. Just as genes propagate themselves in the gene pool by leaping from body to body via sperm or eggs, so memes propagate themselves in the meme pool by leaping from brain to brain via a process which, in the broad sense, can be called imitation." (Dawkins 1989)

A meme is a unit of cultural replication, a cultural instruction if you will, that codes for the cultural equivalent of sneezing. Berman's famous quote, "An idea is something you have; an ideology is something that has you" illustrates the logic in a memetic understanding of human behaviour. For memetics, the human agent can be understood as a system of co-adapted meme-complexes that have infected or been inherited in the brain. Our behaviour is determined by an innate disposition for mechanically and automatically executing and thereby replicating these instructions. From this perspective, a prerequisite for understanding this sort of imitative behaviour is being able to audit and understand the infection strategies of the particular mind viruses resident in our brains. According to memetics, the legitimate focus in the study of human behaviour is the message not the source. We, *ourselves* are held to be emergent properties of an infectious and interacting complex of replicating mind viruses, and our bodies are but vehicles that have evolved to help these replicators, replicate.

Daniel Dennett has summed up the memetic paradigm succinctly

"A scholar is just a library's way of making another library". (Dennett 1990)

From this perspective, memes have us, we don't have them. We are simply user illusions, a neat shorthand for the emergent property of memes competing for space and salience so that they can get replicated. Returning to our reaction to the death of Diana, we have to understand that first rules of memes, or mind viruses - as it is for genes, is that replication is not necessarily *for* anything: Good replicators or good ideas are not necessarily true, good or beautiful ideas, they are simply good at replicating. There need be no rational reason *why* there was such a massive

collective reaction to the death of Diana, it was simply because the Diana crash contagion was particularly infectious, we were predisposed to imitating it. The challenge for memetics is to understand what it is that makes certain mind viruses more contagious than others, by understanding their structure and dynamics.

I know that it is more comforting to think that there are reasons behind our behaviour, that we consciously decide on how to respond to a stimulus, but often it just isn't the case. Memetics argues that we don't have to look for internal explanations for why we behave in certain ways; sometimes we can provide explanations by shifting our focus to the nature of the message itself. How is it that certain mind viruses are more infectious than others, for example, the meme or mind virus whose primary unfortunate symptom is an instruction for the host to go and jump off a cliff? What is the mechanism of infection? How do we develop immunity to some mind viruses and not to others? This is the focus of memetics: Understanding the epidemiology of mind viruses and their associated symptomatologies. Rather than ask why so many of us believe x, or why so many of us behaved in a certain way following say, the death of Diana, memetics asks what is it about our behaviour that made it so infectious, and how did it spread?

Mind viruses spread through a (Darwinian) process of imitation. We know for example that if a suicide is reported in the mass media, the suicide rate will rise in the following month. (Phillips 1986) A few people with poor immunity to this mind virus will become infected and display similar symptoms to the original victim - they will commit suicide. This is called the Werther effect, after Goethe's novel *The Sorrows of the Young Werther*, which was banned in several countries after readers started imitating the hero's suicide (Phillips 1974). We have all heard of copy cat riots, copy cat murders and various other "non-rational" behaviour such as mass suicides of the members of Heaven's Gate and the People's Temple. Conscious choice or contagion? The amount of violence that seen on US television screens correlates positively with US homicides (Phillips 1983). We know as well that suicide victims following a publicised suicide story will more likely than not resemble the reported victim (Phillips 1974). They are victims in very real ways, victims of virulent mind viruses, with symptoms much more deadly than a sneeze. Following the death of Diana, an event witnessed by nearly half of this planet, we can reasonably predict that some immuno-deficient individuals will imitate her behaviour and push up the car fatality figures for September 1997. The relevant statistics are not yet available but I would predict an increase in imitative behaviour among non-married couples. So watch out if you're driving home with you partner tonight - you may suffer from one of the rarer but deadly symptoms of the Diana crash contagion.

And just as we are beginning to see the fruits of genetic engineering, the possibility of memetic engineering is emerging. Because of their substrate neutrality, memes may evolve in computers just as well as human minds, and the Prediction Company in Santa Fe, New Mexico, has been sponsored by US affiliate of the Swiss Bank Corporation to evolve memes that make predictions useful for currency trading (J. Doyne Farmer in Brockman 1996). Memes based on Darwinian algorithms have also helped design fibre-optic telecommunication networks, detect enemy targets in infrared images, improve mining operations, and facilitate geophysical surveys for oil exploration (Cziko 1995). And myself, I make my living out of memes. I am at the grubby end of social science, I get my hands dirty with industry - I develop marketing campaigns and advertising campaigns for multinationals. I build and engineer designer mind viruses, and my

hope today is that I have infected you with a new meme, a meme that could be a useful tool in your new social scientific careers, the meme meme.

Abstract

One of the major challenges currently facing memetics is the issue of how to successfully *operationalise* the emerging paradigm. In other words, how can we exploit the innovative analytical framework of memetics in order to generate a body of theoretically informed empirical research? Whilst there are some important *theoretical* issues that have yet to be resolved, the future success of memetics, qua academic discipline, may depend not so much on elaborate theoretical developments, but on the results of *empirical* research findings. Operationalising memetics will not only involve subjecting memetic theory *itself* to empirical testing, but it will also mean assessing the usefulness of the paradigm in describing, understanding and explaining the sociocultural patterns and phenomena that are the *traditional foci of the social sciences*. To this end, the following paper will explore the operationalisation of memetics by reviewing the work of the David P. Phillips, a sociologist who has been publishing empirical research on social contagions since 1974. Although Phillips has not explicitly referred to memetics, it will be suggested that a number of practical lessons and guidelines may be drawn from his research, and a possible outline for operationalising memetics will be proposed based on his approach.

Summary of empirical research on social contagions conducted by Phillips

The Werther Effect: Fact or Fiction - Summary of Research by D.P. Phillips	
Key findings and Conclusion	Source
Suicide rates increased significantly after suicide stories were reported newspaper stories. The increase was proportional to the amount of newspaper coverage devoted to the suicide stories	American Sociological Review 1974 Vol. 39:340-54
Car accident fatalities increased following media representations of suicide implying that some car accident fatalities were in fact imitative suicides	Science 1977 196: 1464-65
Car accident fatalities, particularly those resulting from single-car accidents increased significantly three days after a suicide story was publicised in the newspaper press. The increase was proportional to the intensity of the publicity, and the age of the accident victim was positively correlated with the age of the suicide story victim. There was also a corresponding correlation between murder-suicide stories and	American Journal of Sociology 1979 Vol. 84 No.5: 1150 -1174

multiple car crashes involving passenger deaths.	
Publicised murder-suicides were followed by an increase in aeroplane crashes (airline and non-commercial). The increase in aeroplane crashes was proportional to the degree of coverage that these stories received	Social Forces 1980 Vol. 58 (Jun): 1001-1024
Daily US suicide rates increased significantly (for a period of less than ten days) following the appearance of highly publicised suicide stories on television evening news programmes.	American Sociological Review 1982 Vol. 47: 802-809
Suicide rates, motor vehicle fatality statistics and non-fatal accidents all rose immediately following the transmission of fictional televised suicide stories in 1977	American Journal of Sociology 1982 Vol. 87 No. 6: 1340-1359
Homicides in the US increased following heavyweight championship prize-fights in a relationship that persisted after correction for secular trends, seasonal and other extraneous variables. The increase was found to be largest following heavily publicised fights.	American Sociological Review 1983 Vol. 48 (Aug): 560-568
Between 1973 and 1979 teenage suicides increased significantly following 38 nationally televised stories of suicide. The intensity of publicity devoted to the suicide stories was significantly correlated to its effect on teenage suicide rates	New England Journal of Medicine 1986 Vol. 315 No.11: 685-9

"No fact is more readily transmissible by contagion than suicide." -- Emile Durkheim (Le Suicide [1897] 1951:141)

In the mid-1770s a peculiar clothing fashion swept across Europe. For no immediately apparent reason, young men started dressing in yellow trousers, blue jackets and open-necked shirts. This mildly eccentric fashion spread from region to region in a manner strangely similar to the epidemics that were continuing to plague the Old Continent. It turned out that these 18th century fashion victims all had one thing in common; they had all been exposed to first novel of Johann Wolfgang von Goethe, *The Sorrows of Young Werther*. Goethe's novel recounted the desperate plight of Werther, a young man hopelessly in love with a happily married woman called Charlotte. In this intense and romantic tale, Goethe describes Werther's rather peculiar penchant for wearing a colourful mélange of blue jackets, yellow trousers and open-necked shirts.

Shortly after being published in 1774, Goethe's novel was banned in several areas across Europe. This was not because certain authorities held it responsible for the spread of a fashion of rather doubtful taste, but because there were signs that the book was also the vector for an altogether more serious contagion. The tale recounted how Werther's clumsy, but painfully sincere, attempts at winning Charlotte's heart ultimately failed. Destroyed by rejection, Werther saw no way out of his desperate plight other than suicide, and using a pistol, he dramatically put an end to his sorrows.

For a memeticist, the social consequences of the publication of Werther's tragic story are entirely predictable: Not only was Werther's dress code the object of imitation but so was his somewhat extreme code of behaviour. Anxious authorities around Europe received reports of

increasing numbers of young men imitating Werther's desperate act. Goethe himself became convinced that his tale was responsible for a continental wave of suicides.

"My...friends thought that they must transform poetry into reality, imitate a novel like this in real life and, in any case, shoot themselves; and what occurred at first among a few took place later among the general public..." (Goethe quoted in Phillips 1974:340)

In an attempt to prevent the suicides from reaching epidemic proportions, a number of authorities banned *The Sorrows of Young Werther* in the hope that the imitative behaviour would cease.

Two hundred years later, in 1974, the sociologist David Phillips coined the term "the Werther effect" to describe imitative suicidal behaviour transmitted via the mass media. Phillips devised an empirical research programme to establish whether media reporting of suicide stories really did affect suicide rates. In over a decade of research, Phillips produced important evidence that supported the hypothesis that behavioural patterns in society can in fact operate as contagions. Methodologically speaking, Phillips' research was interesting because it described one possible solution to the general problem of operationalising the memetic paradigm which, to date, has been dominated by anecdotal evidence.

Phillips' methodological approach could be described as *quasi-experimental* in that his analysis was based on an experimental protocol, but he worked with exclusively historical data sourced in the real, uncontrolled, world. Using newspaper records and official suicide statistics, he identified a number of 'control periods' defined by the absence of front-page newspaper suicide stories. Using the suicide statistics from these control periods, he generated a number of expected suicide rates for a pre-defined selection of 'experimental periods' during which front-page suicide stories were published. Working with a null hypothesis that the front-page newspaper reporting of suicide stories had no effect on aggregate suicide rates, he compared the expected rates with the actual rates. After controlling for seasonal and other spurious effects, Phillips tested for significance between the two values, and by comparing a number of different experimental periods he was able to test for a correlation between suicide rates and the intensity of media representations.

Phillips' technique was unusual in that other experiments on imitation and the mass media have tended to be conducted under artificial laboratory conditions. Whilst some of these experiments have yielded results that point to a correlation between media representations and imitative behaviour (e.g. Bandura, Ross and Ross 1963), they have been largely discounted for failing to accurately replicate the conditions and environment under which memes are transmitted in the heterogeneous and multifaceted social world.

The results of Phillips' quasi-experimental research could not be subjected to this "non-relevance" argument precisely because he was testing for a correlation between media representations and actual social behaviour *in* the social world. Importantly, Phillips was not testing for the relationship between individual behaviour and media representations; rather he was testing for a relationship between suicide rates and media representations. Put differently, Phillips was attempting to provide an explanation of social facts (suicide rates and media representation levels) through social forces (imitation) mediated via the communication

infrastructure of society. Such a macro-level of analysis is of important theoretical significance to memetics since it adds a structural element to a theory otherwise open to the charge of methodological individualism. Severe limitations on space preclude the development of this more theoretical tangent, but it is important to recognise that Phillips was testing for the replication of structural patterns in society rather than investigating the individual process of replication/transmission per se. In this way, his approach is an example of what might usefully be called macro-memetics, in contradistinction to the equally valid micro-memetic approach that currently dominates our paradigm.

Following Phillips' research protocol, such a macro-memetic analysis can be broken down into a certain number of stages that together might outline a possible method for investigating the structural epidemiology of memes:

1. Define the phenotypical expression/symptomatology that will be used to measure levels of meme infection (suicide)
2. Measure the prevalence of meme infection over time within a given population (suicide rates)
3. Measure the exposure rate within a population to this meme through a particular (mass) medium over time (circulation/viewing figures)
4. Calculate an index of exposure intensity (exposure level multiplied by the share of total medium content (column length/no. of days on front page))
5. Define a series of control periods where media transmission intensity = 0
6. Define an experimental period where media transmission intensity > 0
7. Regress meme infection levels during control period(s) to generate an expectation for the experimental period based on the null hypothesis that media representations of the meme have no effect on the incidence or prevalence of that meme
8. Test for significance between the expected and actual results
9. If expected and actual results are significantly different, test for further relationships (host similarity/correlation of intensity and suicide rates)

Figure 1: A New Approach for Memetics?

Such a research programme might yield results providing evidence to support the hypothesis that meme exposure partly determines the incidence and prevalence of meme infection. Put differently, Phillips' macro-memetic approach would help determine whether patterns of behaviour in society do in fact operate in a manner similar to that of contagions. This would provide the empirical foundations for the development of a fuller memetic account of behaviour, providing not only evidence for replication/transmission but also incorporating the processes of variation and selection. If it can be established that social facts may sometimes operate as

contagions, meta-studies of the epidemiologies of various different traits and practices (symptoms of meme infection) might yield clues as to what it is that makes a social contagion infectious, and which factors influence immunity/susceptibility.[1] Further, it might then be possible to measure both the fidelity of sociocultural replication as well as the average time-lapse between exposure and replication (the incubation period). Thus we could begin to generate results around a complete evolutionary loop of variation, selection and replication operating within the (infra) structure of various lines of communication. Mapped over time, structural lineages of mediated traits and practices could provide the basis for a memetic phylogeny of society. This would raise the interesting possibility of an innovative memetic typology of societies derived from the various modes, and relationship to the means, of cultural reproduction. Again, this is a theoretical theme that falls outside the scope of the paper, but such a typology might usefully draw on the social evolutionary theory developed by Jürgen Habermas (Habermas 1979).

Turning now to the empirical results of this 'macro-memetic' research Phillips has provided evidence to support the claim that suicide does indeed behave as a social contagion. Specifically, he demonstrated that exposure to suicide in media stories was a significant variable in accounting for UK and US suicide rates (Phillips 1974). He was also able to show that the intensity of meme transmission correlated positively with suicide rates. In a similar way, Phillips also correlated aeroplane and car accidents, murder and violent crime rates to mass media reporting. (Phillips 1977, 1979, 1980, 1982a, 1982b, 1983, 1986).

The implications of Phillips' research findings were radical; suicide appeared to behave as a contagion mediated via, and dependent upon, lines of mass communication.[2] However, despite consistent findings in favour of this replication/imitation thesis, the Werther effect has not been widely integrated into a comprehensive social scientific understanding of suicide. The reason for this is particularly relevant to memetics and thus merits a brief review.

There are certainly some important methodological problems in Phillips' research that could partly explain why replication/imitation is not a now central concept in contemporary suicide research. In interpreting the results, Phillips appears to make individual-level inferences from aggregate findings (ecological fallacy), he is uncritical of the reliability of official suicide statistics, and he completely ignores the key issues of definition, intention and performance (suicide as opposed to para-suicide (Platt 1984), suicidality (Thorlindsson and Bjarnason 1998), attempted suicide and more generally, risk taking behaviour (Taylor 1982)). These problems have led to an inevitable discounting of his findings in social scientific circles (e.g. Baron and Reiss 1985). The key lesson for memetics here is that it will be important for empirical research to take cognisance of, and address these issues of validity, reliability and meaning. The heterophenomenological approach adopted by Dennett (Dennett 1991) may go some way to address the problems of definition, intention and performance, and the problems of official statistics may be obviated by directly recording prevalence rates. However, the greatest problem for the replication/imitation thesis is theoretical; the Werther effect fundamentally undermines the still dominant Cartesian understanding of the human subject that underpins much social scientific explanation. Social contagions are fundamentally at odds with such an understanding that generally presupposes an irreducible source of intentionality and rationality (economic and cognitive) behind human behaviour. This homuncular understanding of the human subject is part

of what Barkow et al. (1992) have called the Standard Social Scientific Model (SSSM), and its domain assumptions virtually preclude taking evidence of the Werther effect seriously. Whilst the SSSM might accommodate evidence to the effect that the media acts as gate-keeper and agenda setter in the process of communication, any evidence suggesting that we, *ourselves*, are emergent properties of this communication process, rather than vice versa, is incompatible with the 'dogma of the ghost in the machine' that still dominates social science. An alternative understanding of human consciousness, perhaps similar to Dennett's 'Multiple Drafts' functionalist model, will probably have to become firmly established in social science before memetics starts to be taken seriously. Put differently, until Cartesian materialism/dualism ceases to underpin social scientific explanation, the obvious parallel between Darwin and the Creationists will continue to run deep.

However, I do think that Phillips' research has highlighted a weakness in the SSSM, which might provide a more direct opportunity for the establishment of a memetic understanding of suicide and other social behaviour within "respectable social science". This opportunity lies in the very inability of the SSSM to account for the phenomenon of replication/imitation from within its own homuncular paradigm. The more concrete evidence that memetics can provide to support the hypothesis that traits and practices in society do evolve according to principles of variation, selection and replication/transmission, then the more, I believe, the SSSM will be subjected to an increasingly acute crisis of legitimation. This is why I believe the operationalisation of memetics is so crucial to the development of the paradigm.

Interestingly enough, the memetic challenge to the sociology of suicide does have an historical precedent, dating back a hundred years to the competing analytical frameworks of Gabriel Tarde (Tarde [1903] 1962) and Emile Durkheim (Durkheim [1897] 1952). However, Tarde's proto-memetic framework was largely abandoned by sociologists in favour of the approach proposed by Durkheim. In his seminal text, *Le Suicide*, Durkheim explicitly discounted the effects of imitation on suicide rates, arguing that any effect of imitation would be precipitative, minor, and local, and thus insignificant at aggregate level. Whilst the social scientific understanding of suicide has certainly evolved since Durkheim's time, theoretically informed research has tended to either develop out of his original regulation/integration thesis (e.g. Thorlindsson and Bjarnason, 1998), or limit itself to a largely interpretivist critique of his method (e.g. Douglas 1967). However more recently, *empirical* research has begun to include evidence on replication/imitation. This third approach, sometimes known as risk factor analysis, is characterised by the absence of any organising or explanatory principle (Hood-Williams 1996). More of a collection of statistical correlations between antecedent conditions and suicidality than a theory per se, risk factor analysis provides explanations for variations within and between populations that are couched in terms of differential exposure to risk factors (Charlton et al. 1993), *including social contagions*.

This theory-neutral territory is perhaps the ideal ground for developing a comprehensive memetic understanding of suicide. Recent research has tended to confirm the replication/imitation thesis, and has concerned itself with measuring the effects of this phenomenon (Gould et al. 1989 1990). Stack (1990), in a review of research results, concluded that the degree of suicide content in the mass media is indeed an important variable in accounting for varying suicide rates. Further research has been undertaken in order to demonstrate the

circumstances under which the suicide contagion is particularly infectious (Stack, 1987, Bjarnason and Thorlindsson 1994). It is now generally accepted that a spatio-temporal clustering of imitative suicidal behaviour does occur, and that the Werther effect may account for a significant proportion of youth suicides in the US (Gould et al 1989). In consequence, a US Government endorsed programme on suicide contagion has now been set up to provide guidelines and recommendations for minimising the Werther effect,[3] and a similar Government project also exists in Australia.[4]

However, as critics of Phillips' research have pointed out (e.g. Baron and Reiss 1985:361), without a credible theory of contagion or imitation upon which hypotheses may be tested, quasi-experimental research findings, such as those of Phillips, may invite ex-post reinterpretations as to the nature and existence of these putative social contagions. This means that until a comprehensive theory of replication/imitation is developed, evidence will probably be simply ignored because it doesn't 'fit' the SSSM. This, of course, is where I believe the opportunity for memetics lies, through the *theoretically informed provision* of empirical evidence of contagion and imitation from an alternative non-homuncular paradigm.

The purpose of this paper has not been to develop a memetic theory of suicide, (a central task of my DPhil thesis) but to demonstrate the pertinence of Phillips' research for the memetic paradigm methodologically, empirically and politically. Health authorities, if not academia, already accept the central tenet of our paradigm, and this important fact may provide memetics with a key opportunity for developing academic respectability and funding. A memetic approach, operationalised as *the epidemiology of social contagions in society* could build on research such as that conducted by Phillips, and could capitalise on the inability of current paradigms to adequately deal with the phenomenon of replication/imitation. Operationalising memetics as epidemiology suggests that one of the central tasks of our discipline may be to map the structural evolution and spread of social patterns of behaviour within society in terms of the familiar evolutionary loop of variation, selection, and replication. This macro-memetic approach could be complemented by, and conceptually integrated with, the micro-memetic analysis of differential infection as proposed by Lynch (1997) and Brodie (1996). These complementary approaches might provide the basis for a comprehensive analytical framework for generating a body of theoretically informed evidence relating to social contagions, which in turn might lay the foundations for the long overdue Kuhnian paradigm shift that will finally see the integration of social science within a broader evolutionary paradigm.

Notes and References

[1] This research might perhaps draw on the research of McGuire (1964) who has developed an inoculation model in the social psychology of persuasion.

[2] Other researchers have subsequently adopted Phillips' quasi-experimental approach to demonstrate that other traits and practices may operate as social contagions transmitted via the mass media (e.g. Mazur 1982 on bomb threats)

[3] The suicide contagion thesis has impacted on public policy in the U.S. following a recent CDC (Center for Disease Control and Prevention) endorsed national workshop (CDC 1994).

MEMETICS ON THE EDGE OF CHAOS

A Review of:

Shifting the Patterns: Breaching the Memetic Codes of Corporate Performance

by If Price and Ray Shaw, (1998). Management Books 2000 Ltd, UK. ISBN 1-85252-253-4

By

Paul Marsden

PaulMarsden@msn.com

Shifting the Patterns (STP) is the first of a new generation of books that attempts to apply a memetic stance to describe, explain, and suggest solutions to real-world issues and problems. The memetic stance involves taking a 'meme's-eye view' of the social world, and analysing social phenomena as if human agents were vehicles for these replicating cultural traits (Marsden). The authors apply such a memetic stance to corporate culture and management theory, and in doing so develop a broadly memetic understanding of organisations.

Essentially, STP is an excursus into the idea that companies are both constructed and constrained by the patterns of beliefs and rules (memes) that produce behaviour, and ultimately determine commercial performance. To change the patterns of performance, it is necessary to change the patterns of beliefs and rules (both explicit and implicit) that determine that performance. To this end, the authors argue against the application of quick fix management fads, and for a deeper understanding of the patterns that code for performance.

According to Price and Shaw, company performance is largely the product of the unchallenged and blind application of past patterns of behaviour. The authors urge us to realise that we are not simply narrators or passive victims in this process; rather we are creative actors in the ongoing production of these patterns. We have the power to shift the patterns. The authors promote a velvet revolution in corporate culture where managers rebel against the proverbial "*tyranny of the replicators*" (Dawkins 1976/1982), see the strings by which they are moved, and take the first step to freedom (and, of course, improved performance).

STP is both engaging and stimulating, drawing together many themes of contemporary management theory and presenting them in one broadly memetic framework. In doing this, the authors demonstrate the flexibility, power and potential of the memetic stance. The book provides useful chapter by chapter summaries as well as comprehensive listings of sources for further reading. Whilst the specific recommendations in STP for corporate strategy and management theory are interesting in their own right, the focus of this review will restrict itself to an assessment to the authors' particular application of meme theory.

Importantly, STP is not a book about memetics; rather it uses the memetic stance as a vehicle for providing a critique of companies that can become mindless structures replicating themselves through time and space, and where employees can become largely passive cogs in the corporate machine. In Chapter 4: The Pattern's Eye View, the authors borrow from meme theory by

"set[ting] out an unconventional perspective on companies, arguing that they are best interpreted as vehicles, or hosts, for a meme's - or pattern's - replication."

Rather than adopting the conventional view that individuals are the hosts for memes, this *"unconventional perspective"* holds that companies should be understood as the proper hosts for memes. Embracing 19th Century organicism (Spencer 1969), the authors suggest that organisations can be understood *"as 'living', self-organising, self-maintaining entities"*, and these entities are the proper hosts for memes. Specifically, the meme concept is introduced as a heuristic device for understanding the components (sets of beliefs and rules) of the patterns which define the organic company.

Memes (beliefs and rules), both explicit and implicit, are held to coalesce into paradigms that can be understood as *"memomes"*, that produce the phenotypic expression of the company; its pattern and performance. This unorthodox understanding of the relationship between meme and organisation such that *"as the organism is to the gene, so the organisation is to the pattern or meme"* is not without problems, particularly when compounded with the organism/company (dis)analogy. (Organisms are not physically bonded, rather relations between their constituent parts are purely informational: Organisations themselves do not reproduce whereas organisms do: Unlike organisms, organisations have phylogenies: Organisations do not have needs themselves, unlike organisms.)

Just as the company/organism analogy is problematic, the authors seem to exacerbate problems in the already partial gene/meme analogy by conflating 'pattern' and 'meme': It is not clear whether they understand memes as the nodes of patterns or relations between them, or indeed, both. However, the problem becomes yet more confused when the authors employ a more conventional understanding of memes, as socially inherited cultural instructions. Finally, the authors' blanket statement that memes are also the stuff of *"mental models, paradigms, languages, traditions, habits and rules; inter-related units of a cultural or economic code; widely shared patterns of perception, communication, understanding, appreciation and tradition"* stretches the meme concept to such an extent that it loses not only explanatory power and heuristic provocativeness, but also meaning. Importantly, the authors seem to confuse the issue of whether individual brains or companies are hosts to memes. In arguing that companies are both sets of rules, and hosts of those rules, the authors appear to be arguing that a set of memes somehow constitutes a host. This is deeply confusing and results in the loss of any potential clarity and coherence that the memetic stance might have.

The ambiguity over what the authors mean when they are referring to memes is further exacerbated by a tendency to switch freely between loose gene and virus analogies. Memes are held to code for organisations, whilst at other times they are presented as viral *"antibodies to change"* that hijack the organisation for their own reproduction. This confuses both the unit and the level of evolution. It is not at all clear whether rules evolve, organisations evolve, or more amorphously, patterns (of rules, behaviours and organisations) evolve. The definition of the meme as proposed by the authors does little to clear this ambiguity.

"An organism is coded via chemical strands of DNA, sections of which form genes, the smallest units capable of being copied. An organisation is coded via 'ideas and images of the mind',

abstract strands of thinking, perception and language, the smallest units of which can be thought of as memes which may be interpreted as: the smallest element capable of being exchanged, with an associated sense of meaning and interpretation, to another brain."

'Abstract strands of thinking' aside, the cogency of STP only holds together if memes are conceptualised as rules or instructions that code for an organisation. This would render the framework presented by the authors broadly compatible with Cloak's cultural ethology of i-culture and m-culture (Cloak 1975). Indeed, the authors might have usefully exploited the clarity of Cloak's framework in the development of their own position.

The authors' central tenet is that that these rules/patterns/organisations/memes/abstract-strands-of-thinking evolve selfishly to their own, rather than their human hosts', agenda, a 'fact' that is posited more by partial analogy to genes/viruses as opposed to supported by evidence. However, it is not at all clear why or how these cultural critters should evolve selfishly, since the environmental conditions (resource insufficiency) necessary for evolution to occur are not made explicit. In fact, whilst this is a central theme of the book, virtually no consideration is given to how patterns evolve within the framework developed. A simpler and more credible explanation would be to account for alienation in terms of conflicts of interests; anonymising exploitation using convenient selfish memes is a cheap trick. If the authors wished to develop a truly memetic approach to organisations, they might have usefully drawn on Allison's (1992, 1993) work on the spread of non utility-maximising rules through populations.

Whilst it is unfair to criticise STP for ideas that are not developed, it is nonetheless surprising that the authors chose not to develop, or even refer to, the leading proponents of their own understanding of organisations, that is, the neo-Darwinian theory of institutions developed by Burns and Dietz (1992, 1996, 1997a, 1997b, Dietz and Burns 1992, Dietz, Burns and Buttell 1990). Similarly, the absence of any reference to the established field of ethnomethodology (Garfinkel 1967, Zimmerman 1971) whose central concern is the understanding social behaviour in terms of the maintenance and evolution of the rules (written and unwritten) that code for that behaviour, is somewhat surprising. Had the authors chosen to develop insights from these perspectives, STP might have gained in coherence and clarity.

As it stands, the coherence of STP is apparent only when it is understood that the authors are simply borrowing elements from evolutionary thought and meme theory, and employing these elements to make a number of specific points not necessarily related to either evolution or memetics. Evolutionary and memetic concepts are simply used as metaphors full of pregnant analogies for the corporate world. It would be unfair to criticise the authors for being selective, uncritical and unrepresentative in this use of these bodies of thought, because they did not set out to be comprehensive, critical and representative in the first place. However, readers unfamiliar with the central ideas of evolutionary thought and meme theory are likely to come away from STP with a somewhat misleading understanding of the two bodies of thought. For example, the authors authoritatively state that evolution is characterised by long periods of stasis punctuated by crisis and rapid change, and that "*evolution is either revolution or it is nothing*". Perhaps, but reports of the death of gradualism have been greatly exaggerated, and Gould is not the only evolutionist around.

The most controversial aspect of STP for memeticists is probably the authors' insistence that we, ourselves, can step miraculously outside the memetic evolutionary process and, by virtue of our non-memetic independent freewill, rebel against the tyranny of the cultural critters. In other words, the dualist homunculus is left untouched by the authors' conceptualisation of memetics. Memes are considered alien parasites that infect companies (but oddly, also code for them at the same time) but which are nevertheless dependent on our willingness to replicate them. Thus, according to the authors, we can direct the evolution of companies through the selective transmission and the creation of new memes derived from our new understanding of the patterns that code for performance.

"The key difference is that this does not have to be left to accident or random variation. We can, by human intention and creative act, wilfully change the basis upon which any pattern of company is built."

"People can choose to break the grip of a prevailing pattern. Punctuating organisational equilibria intentionally, shifting patterns rather than waiting for history to shift them for you, is the key to the self-generative system."

This homuncular-speak sits uneasily with meme theory, which has largely been concerned with deconstructing pervasive homuncularism in understanding human behaviour (Blackmore forthcoming, Dawkins 1976/1982, Dennett 1990, 1991, 1995, Rose 1998, Marsden). If the authors wish to argue for empowerment and change, and against the blind following of socially inherited rules that perpetuate past patterns of individual and corporate behaviour, then they do not need memetics; indeed the use of the memetic stance is positively confusing in this respect. Neither do they need memetics to argue that companies, or indeed the rules that code for companies, evolve in ways that are alienated from the concerns of those that perpetuate them. Standard conflict theory and the introduction of the notions of power, coercion and exploitation to the analysis would make for adequate explanation of this phenomenon within the safe homuncular framework that the authors seem to wish to retain. By shying away from the deconstructive implications of the memetic stance, and by refraining from developing their theory in terms of the evolutionary loop of replication, variation and selection, STP gets a raw deal from memetics and evolutionary thought, inheriting many of the weaknesses and ambiguities, without capitalising on the strengths.

The final chapter of STP concludes with a heady cocktail of chaos theory and memetics couched in hyperbola under section headings such as *"When butterflies flap their wings: The shifting patterns of our time"*, *"Slaves to, or shifters of, patterns?"*, *"Where butterflies flap their wings, people infect minds!"* *"Breaking out of the cocoon: Existential fears to existential breakthroughs"*, and *"Bringing forth a world: letting the genie out of the bottle"*. The message here is one of empowerment, that whilst we are the products of our memetic inheritance, we also have the power to shift the patterns, to rebel against the tyranny of the memetic replicators, in a world where small changes can have major effects. This truly is memetics on the edge of chaos.

MEMETICS AND SOCIAL CONTAGION: TWO SIDES OF THE SAME COIN?

By

Paul Marsden

Graduate Research Centre in the Social Sciences

University of Sussex

PaulMarsden@msn.com

Abstract

Following a thematic overview of social contagion research, this paper examines the question of whether this established field of social science and the nascent discipline of memetics can be usefully understood as two sides of the same coin. It is suggested that social contagion research, currently lacking a conceptual framework or organising principle, may be characterised as a body of evidence without theory. Conversely, it is suggested that memetics, now over two decades old but yet to be operationalised, may be characterised as a body of theory without evidence. The article concludes by proposing a memetic theory of social contagion, arguing that social contagion research and memetics are indeed two sides of the same social epidemiological coin, and ends with a call for their synthesis into a comprehensive body of theoretically informed research.

1 The Contagion Phenomenon

Two centuries ago, a wave of suicides swept across Europe as if the very act of suicide was somehow infectious. Shortly before their untimely deaths, many of the suicide victims had come into contact with Johann von Goethe's tragic tale "The Sorrows of Young Werther," in which the hero, Werther, himself commits suicide. In an attempt to stem what was seen as a rising tide of imitative suicides, anxious authorities banned the book in several regions in Europe (Phillips 1974, Marsden 1998).

During the two hundred years that have followed the publication and subsequent censorship of Goethe's novel, social scientific research has largely confirmed the thesis that affect, attitudes, beliefs and behaviour can indeed spread through populations as if they were somehow infectious. Simple exposure sometimes appears to be a sufficient condition for social transmission to occur. This is the social contagion thesis; that sociocultural phenomena can spread through, and leap between, populations more like outbreaks of measles or chicken pox than through a process of rational choice.

The term contagion (kan-tā'jan) itself has its roots in the Latin word *contagio*, and quite literally means "and from touch". Contagion therefore refers to a process of transmission by touch or contact. The Microsoft Dictionary (Microsoft 1997) defines contagion as the

"transmission of a disease by direct contact with an infected person or object; a disease or poison transmitted in this way; the means of transmission; the transmission of an emotional state, e.g. excitement; a harmful influence."

From this definition, contagion refers to 1) the social transmission, by contact, of biological disease, and 2) the social transmission, by contact, of sociocultural artefacts or states. The contagion concept first became popular as both a descriptive and explanatory device for social, as opposed to biological, phenomena in the late 19th century France, notably through the work of James Mark Baldwin (1894), Gabriel Tarde (1903) and Gustave Le Bon (1895). Empirical research into the phenomenon did not, however, begin until the 1950s. This more recent research has unequivocally established the fact of the social contagion phenomenon, and has identified its operation in a number of areas of social life. The implications of this social contagion research are radical: The evidence suggests that under certain circumstances, mere 'touch' or 'contact' with culture appears to be a sufficient condition for social transmission to occur.

Despite this promising start, social contagion research has evolved into a field that is now unorganised, disparate and incoherent, lacking both an organising principle and a conceptual framework (Levy and Nail 1993). There is, in fact, a complete absence of agreement among researchers as to the particular mechanism that underlies social contagion. This lack of consensus has led to a proliferation of definitions of the phenomenon which range from the vague to the plain contradictory. For example, the Penguin Dictionary of Psychology (Reber 1995) defines contagion simply as the "*spread of an activity or a mood through a group*". The Concise Oxford Dictionary of Sociology (Marshall 1994) adopts a similarly vague definition of "*ideas moving rapidly through a group*." Other definitions, whilst more extensive, provide little in the way of increased clarity or utility. The Macmillan Dictionary of Psychology (Sutherland 1995) defines contagion as "*the spread of ideas, feelings and, some think, neuroses through a community or group by suggestion, gossip, imitation etc.*" Some definitions attempt to clarify the concept in terms of a putative uncritical and non-rational mode of inheritance/infection. Thus, The Encyclopaedic Dictionary of Psychology (Furnham 1983) defines contagion as a process and form of collective excitement "*in which emotions and behavioural patterns spread rapidly and are accepted uncritically by the members of a collective*." In contrast, other definitions make no mention of this uncritical nature of inheritance but specify instead the perception of non-intentionality in transmission (e.g. Levy and Nail 1993) such that contagion becomes the "*spread of affect, attitude or behaviour from Person A ("the initiator") to person B ("the recipient") where the recipient does not perceive an intentional influence attempt on the part of the initiator*." A very different definition of contagion has also been proposed, referring to neither the non-intentional nature of transmission, nor the uncritical nature of inheritance, but rather to a putative phenomenon of disinhibition. Thus, Wheeler (1966) states that:

"If the set of test conditions T1 exists, then contagion has occurred if and only if Person X (the observer) performs behaviour N (BN) where T1 is specified as follows: a) A set of operations has been performed on Person X which is known to produce instigation toward BN in members of the class to which X belongs; b) BN exists in the response repertoire of X, and there are no physical restraints or barriers to prevent the performance of BN; c) X is not performing BN; d) X observes the performance of BN by Person Y (the model)." (p. 180)

Together, these very different definitions of contagion have been operationalised to produce studies that have little in common except the observable phenomenon of spread by contact. Most of these insist on the presence of a number of internal states and mechanisms (intentionality, approach-avoidance, conflict etc.) for the process to count as 'true', as opposed to merely 'apparent' contagion. However, these various qualifications have not only contributed to the confused nature of social contagion research, but they have also undermined the central rationale of the metaphor; that observable culture spreads as if it has contagious properties.

One of the clearest and most inclusive definitions of social contagion is that proposed by The Handbook of Social Psychology (Lindzey and Aronson 1985). This definition refrains from positing as necessary internal states. Instead social contagion is held to be "*the spread of affect or behaviour from one crowd participant to another; one person serves as the stimulus for the imitative actions of another.*" Such a definition has the advantage of focusing and clarifying the observable contagion phenomenon, whatever internal states may or may not be present. It should be noted however that there is no reason for the contagion phenomenon to be restricted to the crowd scenario, to be sure, the mass media allows for the possibility of contagion through dispersed collectivities.

2 Social Scientific Research on Social Contagion

Despite the varied definitions of contagion, the empirical research has tended to confirm that the hypothesis that human behaviour clusters in both space and time even in the absence of coercion and rationale. This tendency towards homogeneity has been identified in a number of types of behaviour using one or more of three basic approaches. In the case of dispersed collectivities or masses, evidence for and against the social contagion phenomenon has been typically drawn from correlational studies where aggregate statistics on exposure and infection are correlated, such as media reporting on suicide stories and suicide rates (e.g. Phillips 1974, Marsden 1998). In the case of local collectivities such as crowds, research methods have included field studies using participant or non-participant observation (e.g. Reicher 1984 on Bristol riots), or formal experimental studies under laboratory conditions (e.g. Freedman, Birsky and Cavoukian 1980). Bringing the disparate data from the various methods together, meta-analyses of the contagion phenomenon have also been conducted (e.g. Levy and Nail 1993).

Substantively, social contagion research can be broken down into two major areas, studies investigating emotional contagion (the spread of mood and affect through populations by simple exposure) and studies investigating behavioural contagion (the spread of behaviours through populations by simple exposure). Behavioural contagion research can itself be broken down into six broad areas, based on the nature of the behaviour that is spread; hysterical contagions, deliberate self-harm contagions, contagions of aggression, rule violation contagions, consumer behaviour contagions, and financial contagions.

A hysterical contagion is "*the dissemination of a set of symptoms among a population in which no manifest basis for the symptoms may be established.*" (Kerckhoff and Back 1968). Also known as contagious psychogenic illness (Cohen, Colligan, Wester II and Smith 1978), hysterical contagions involve the spread by contact of reported symptoms and experiences usually associated with clinical hysteria (hallucinations, nausea, vomiting, fainting etc.) in the

absence of a biological contagion. The paradigmatic example of hysterical contagion is the "June Bug" incident that occurred in a US textile factory in 1962, where 62 factory workers reported having been bitten by a mythical bug that 'caused' symptoms such as numbness and nausea (Kerckhoff and Back 1968). More recently, Colligan and Murphy (1982) have analysed a further 23 examples of hysterical contagion - "*the collective occurrence of a set of physical symptoms and related beliefs among two or more individuals in the absence of an identifiable pathogen*", and found that it was the verbal reporting of the symptoms that spread in a contagious-like manner rather than the symptoms themselves. Their research also largely confirmed Kerckhoff and Back's theory that those susceptible to hysterical contagion were suffering from intra-psychic stress. More recently still, Showalter (1997) has suggested that chronic fatigue, Gulf war and multiple personality syndromes might spread by contagion, and Pfefferbaum and Pfefferbaum (1998) have argued post-traumatic stress disorder also spreads by contagion. The hallucinatory component of hysterical contagion may also account for the spread of supernatural phenomena such as the sightings of Diana ghosts following the death of the princess in 1997 (Marsden 1997), as well as reports of UFO sightings and alien abductions (Houran and Lange 1996, Showalter 1997).

A second class of behaviour that appears to spread through populations by contagion is rule breaking or rule violation behaviour. Evidence has tended to support the thesis that an individual's exposure to rule violations increases their likelihood of engaging in similar or identical behaviour. Such rule violation contagions have been identified in teenage smoking (Ritter and Holmes 1969, Rowe, Chassin, Presson, Edwards and Sherman 1992), speeding (Connolly and Aberg 1993), substance abuse (Ennett, Flewelling, Lindrooth and Norton 1997), delinquency (Jones 1998), youth sex (Rodgers and Rowe 1993) and criminality (Jones and Jones 1995).

A third class of behaviour, which has been the focus of empirical social contagion research, is deliberate self-harm (DSH), of which suicide is the paradigmatic example. Specifically, research has shown that suicide rates and other examples of DSH vary proportionally to the extensity, intensity and content of exposure, both in local and dispersed collectivities (Phillips 1974, 1980, 1982, Stack 1987, 1990, Higgins and Range 1996, Gould 1990, 1996, Gould, Wallenstein and Kleinman 1987, Gould, Wallenstein and Davidson 1989, see Marsden 1998 for a 'memetic' overview). Contagion is now an accepted risk factor in suicide research, and the overwhelming evidence has prompted the establishment of several government programmes to minimise the effects of suicide contagion.

Another, very different focus of social contagion research has been the financial contagion phenomenon, manifested in the behaviour of stock markets which lurch from state to state as a result of selling panics and buying frenzies that sweep across the globe. Financial contagion research has tended to investigate the various factors that may exacerbate and contribute to the phenomenon such as analysis techniques, the level and nature of information available to dealers, and social communication networks (e.g. Orlean 1992, Temzelides 1997, Lux 1998).

A fifth area of contagion research has investigated the contagious properties of consumer behaviour which sometimes results in the spread of consumer fashions and fads through populations in a manner more indicative of an influenza epidemic than rational behaviour

(Marsden, forthcoming b). This phenomenon has prompted the development of deterministic and stochastic models with good predictive power that forecast both sales realisation and new product adoption patterns based on the 'infectiousness' of consumer goods (Bass, Mahajan and Muller 1990, Rashevsky 1939, 1951, Rapoport 1983, Rogers 1995).

A sixth focus of social contagion research has been the contagion of aggressive behaviour, a phenomenon that has been shown to operate in both local and dispersed collectivities. Whilst much of this research has been of a descriptive nature within transitory and unpredictable angry crowds (mobs) (Bandura 1973, Reicher 1984, Lachman 1996), results have been supported with experimental evidence (Bandura, Ross and Ross 1963, Wheeler and Caggiola 1966, Wheeler and Levine 1967, Wheeler and Smith 1967, Goethals and Perlstein 1978). In dispersed collectivities, where the contagion of aggression is mediated by the mass media, research has focused on measuring exposure and infection rates and then testing for correlations. (Atkin, Greenberg, Korzenny, and McDermott 1979, Sheehan 1983, Phillips 1983).

Finally, social contagion research has not only restricted itself to the spread of behaviours, a significant number of studies have identified a variety of emotional contagions. The emotional contagion phenomenon was originally defined by McDougall (1920) as "*the principle of direct induction of emotion by way of the primitive sympathetic response*" and more recently by Sullins (1991) as "*the process by which individuals seem to catch the "mood" of those around them*". The proposed mechanism for this spread of mood is an automatic and continuous human tendency to synchronise facial expressions, voices, and postures with others in the immediate environment (Hatfield, Cacioppo and Rapson 1993). These behavioural cues then appear to trigger the appropriate emotions in a system of feedback. The Emotional Contagion Scale (Doherty 1997) has been recently developed and validated to assist further research in this area, which has already identified various examples of emotional contagion including mood (Hsee, Hatfield and Chemtob 1992), anxiety (Behnke, Sawyer and King 1994), fear (Gump and Kulik 1997), appreciation (Freedman and Perlick 1979) and enjoyment (Freedman et al. 1980).

3 The Social Contagion Phenomenon Explained (Away)?

Whilst the vast majority of social contagion research has demonstrated the existence and voracity of the empirical phenomenon, the theoretical implications of the results have not been addressed. The results of contagion research suggest that just as we do not choose to be infected with, and pass on, biological contagions, we often behave as if we have little control over the culture we become infected with and consequently spread. Such an observation undermines the traditional understanding of the human subject as an autonomous agent whose action is defined by individual intentionality and rational evaluation. Whilst we may like to believe that we consciously and rationally decide on how to respond to situations, social contagion evidence suggests that some of the time this is simply not the case. Rather than generating and 'having' beliefs, emotions and behaviours, social contagion research suggests that, in some very real sense, those beliefs, emotions and behaviours 'have' us.

The failure of mainstream social science to take this implication of social contagion evidence seriously is certainly in part due to the above-mentioned disorganised and incoherent state of the field. However, the failure is also probably due to a fundamental incompatibility between the

concept of social contagion and the Cartesian voluntarism implicit in much social science. In fact, standard explanations of social contagion can be characterised by an almost desperate attempt to restore irreducible individual agency and rational action to the phenomenon. In trying to explain away the social contagion phenomenon, two types of theory have been developed. Firstly, a number of theories suggest that the spread of homogeneity is a consequence of conscious and deliberate imitation in situations usually defined by uncertainty or ambiguity. Secondly, contagion has been accounted for by putative latent homogeneities in terms of prior motivations that antecede the observable phenomenon.

An example of the first type of explanation is Emergent Norm Theory (e.g. Turner 1964) which states that the spread of behaviour through a population is not by contagion (contact) but is the result of conscious and deliberate attempts to adhere to norms and rules emerging out of complex and subtle interaction within collectivities. Similarly Social Learning Theory (e.g. Bandura 1971, 1986) holds that homogeneity is the result of the conscious and deliberate imitation that takes place when individuals are presented with uncertain and ambiguous situations. When we are unsure of how to react to a stimulus or a situation, these theories suggest that we actively look to others for guidance and consciously imitate them.

An example of the second type of explanation is Convergence Theory (e.g. Turner and Killian 1987) which suggests that homogeneity and clustering is not a result of contagion but the result of prior shared motivations that cause collectivities to converge in the first place. From this perspective, similarities cause collectivities and not vice versa. A similar explanation is provided by Disinhibition Theory (e.g. Freud 1922, Redl 1949, Wheeler 1966, Ritter and Holmes 1969, Levy and Nail 1993) which states that contagion is "*essentially imitation mediated by restraint release due to observing another perform an action that the individual is in conflict about performing himself*" (Freedman 1982). In other words, from this perspective, behaviours are not transmitted by contact; rather inhibited behaviours (sometimes unconscious and "primitive") that are already held in an individual's behavioural repertoire are simply released. Thus, homogeneity spreads as a result of the intra-psychic conflict resolution that occurs through social evidence. Another variation on the 'prior motivations' theme is Deindividuation Theory (e.g. Diener 1976, 1979, Festinger, Pepitone and Newcombe 1952, Zimbardo 1969). This theory holds that the anonymous nature of collectivities can engender a restraint reduction in individuals. This sense of anonymity is held to cause a reduction in the individual's sense of personal accountability and responsibility, allowing them to engage in behaviour from which they might otherwise abstain. When anonymity leads to restraint reduction of similar behaviours within individuals within a collectivity, this produces the appearance of contagion.

Both the 'conscious choice' and 'prior motivations' theories may explain the social contagion phenomenon in some circumstances, but none of them can comprehensively explain the phenomenon. Indeed, it is difficult to see how any of the theories could provide a credible explanation of either emotional or hysterical contagion, except by maintaining that we either choose illnesses or emotional states based on those that are around us, or worse we have hidden desires to be ill, angry or anxious! Social contagion stretches Cartesian rational action theory to such a degree that the latter becomes an untenable explanation of the former. Valiant attempts at squeezing irreducible individual agency and rational evaluation into the phenomenon are simply at odds with data. The evidence shows that we inherit and transmit behaviours, emotions, beliefs

and religions not through rational choice but contagion. Does this rejection of rational choice/action theories mean that social contagion is a homeless body of research, a body of evidence with no theoretical home to go to? No, I think there is an alternative paradigm that has the potential to explain more of the data more of the time. That paradigm is memetics.

4 The Memetic Stance

Social theorists often use the language of architecture, they speak of theory building, laying theoretical foundations, or constructing theoretical edifices. This is useful language; it indicates the step by step, laborious nature of their enterprise. Meme theory is no different in this respect; many problems still have to be resolved within the new paradigm (Rose 1998). However, meme theory is developed enough to be operationalised conservatively by adopting what could reasonably be called a memetic stance. Not a fully blown theory, the memetic stance is more of a way of looking at the world, a set of guiding principles, a useful heuristic, based on some hopefully important insight into the nature of the social world. Whether the memetic stance turns out to be an explanatory device in an evolutionary extension of folk psychology, or a proper theory of mind where memes are internally instantiated in the neural networks of our brains, is an issue that will one day have to be resolved empirically. For now, by adopting the memetic stance, these issues may be bracketed, and research can proceed based on the utility of this ontologically minimalist heuristic.

So what exactly is the memetic stance? The memetic stance states that human condition is minimally defined by two selective processes operating in two different substrates, the biological and social (Marsden forthcoming a). This is because the necessary conditions for the evolutionary loop of replication, variation and selection are present in the two substrates. This is not contentious in itself, what is more contentious is that the memetic stance sees these processes operating at the level of what is being replicated, that is, the gene and the meme. Thus, the memetic stance involves taking a meme's-eye perspective and understanding of the social world, thinking not in terms of selfish genes, but selfish memes. Taking this memetic stance has allowed researchers to explain the spread of non-rational behaviour in terms of the fitness of that behaviour itself. Examples include altruism (Allison 1992, 1993, Blackmore forthcoming) chain letters (Goodenough and Dawkins 1994, Hofstadter 1995, Allison 1993), chain e-mail (Jones 1995) religions and cults (Dawkins 1993, Lynch 1996 and Cowley 1997), political revolutions and war (Vajk 1989), religious scriptures (Pyper 1997) Usenet content (Best 1997), management practices (Price and Shaw 1996, 1998), media representations, (Rushkoff 1994), urban legends (Gross 1996) and consumer behaviour (Marsden forthcoming b, Brodie 1996).

The memetic stance suggests that design in the social world is at least partly a product of the evolutionary loop of replication, variation and selection operating on culture, or more specifically cultural instructions coding for behaviour (Cloak 1975, Marsden forthcoming a). It is not necessary to invoke conscious choice or rational evaluation by an entity - homuncular, divine or otherwise - standing miraculously outside evolution to explain design; given enough iterations, natural selection will inexorably and inevitably give rise to design.

Once we take the memetic stance, features of the world that are difficult to explain from the orthodoxy of traditional social science become non-miraculous and eminently explicable. The

memetic stance can explain not only apparent design in the social world, but importantly it can also explain phenomena that seem to negate the omnipresence of individual agency in human affairs. Put simply, the memetic stance states that the reason why some social behaviour doesn't seem to make sense from the perspective of the individual is because we are looking at that behaviour at the wrong level. We are taking an anthropocentric or homuncular view of a social world that was created at least in part at a memetic level. Trying to explain the social world from the perspective of the individual is like trying to explain the movements of a car without reference to the driver. The movements of a car can be rationally described, explained and understood in terms of the car's own needs as (somewhat circuitous) trips from petrol pump to petrol pump. However, by ignoring the driver much of what is observed makes no sense at all. The same argument holds for the social world, just as we can explain much of our (somewhat circuitous) social behaviour in terms of the needs of the meme-vehicle (individual), much of what is interesting about that behaviour is overlooked. By taking the memetic stance we can account for what happens when the needs of an individual cannot explain behaviour, the equivalent of all the non-petrol seeking activity of a car, and this stance provides an evolutionary rationale for explaining why the social contagion phenomenon occurs.

5 Social Contagion from the Memetic Stance

Taking the memetic stance involves, to use an overused concept, a true Kuhnian paradigm shift; just as evolution in the biological world evolves according to what is better (not best) for the gene in its environment, so too does the social world evolve according to what is better for the meme. The memetic stance involves describing, explaining and understanding social behaviour from this meme's-eye perspective. From the memetic stance "What makes this person want to do x?" becomes "What is it about x that makes people want to do it?" Social contagion can be explained by the memetic stance because culture has an independent evolutionary dynamic that is derived from the genetically evolved human capacity and predisposition to replicate culture (see Flinn 1997 for a review). Because social learning is an evolved psychological trait, it follows that we have an evolved predisposition to replicating the behaviour of those around us. Successful social contagions are those elements of culture that operate as both stimulus and response, and that are adapted to the evolved architecture of the human brain. No homunculus need be invoked, only evoked imitation.

In this way, the memetic stance deconstructs the homunculus into what can be understood as replicating cultural instructions (memes). This opens up an exciting research programme for memetics, as contagion is no longer understood as a metaphor but an evolutionary process. Social contagion research, from the memetic stance could focus on the particular characteristics that render behaviours and emotions infectious. It could also investigate why certain people are immune to certain contagions, or how they develop resistance to contagion, or conversely what makes certain people particularly susceptible to contagion, and others not. Similarly, memetic research could look for the limiting factors of the contagion phenomenon in both time and space. How, for example, is social contagion bounded? Can social contagion epidemics burn themselves out and if so, how? How does a contagious epidemic become an endemic trait in the social world? Is it possible to quarantine areas exposed to contagion, or quarantine those who have been infected? Can individuals be vaccinated against contagion? How long is the incubation period, that is, the time from exposure to infection? What are the primary vectors of

contagions, that is, what are the primary channels of infection? Are contagions specific or diffuse? These are all questions that are more or less precluded in a traditional paradigm dominated by a Cartesian homuncularism and rational action theory which essentially deny the existence of the social contagion phenomenon. By deconstructing the homunculus into a web of replicating instructions, the memetic stance allows the social contagion phenomenon to become a theoretically informed research enterprise.

6 Memetics and Social Contagion: Two Sides of the Same Coin?

Taking the memetic stance allows research to proceed with the objective of explaining the spread of non-rational behaviour in terms of the fitness of that behaviour itself. Until recently, such memetic research has been of a largely non-rigorous and anecdotal nature. Despite offering the exciting prospect of being an autonomous social theory that is compatible and coherent with, but not reducible to, our knowledge of the biological world, the emerging discipline of memetics has yet to produce any concrete results. This is essentially because the issue of how to successfully operationalise the emerging paradigm has yet to be addressed; memeticists have yet to exploit their innovative analytical framework to build a body of theoretically informed empirical research. It is here that the body of social contagion research may be of particular use to memetics, offering itself up as a rich source of empirical evidence, whilst offering important methodological lessons and inspiration for future research. For example, the emotional contagion scale developed by Doherty (1997) could be used by memeticists, as could the field studies, correlational and experimental methods that have been exploited by social contagion researchers.

More generally, memeticists could develop the social contagion research tradition of using the substrate neutral tools of epidemiology to assist their research programme. These tools could be adapted to provide useful information about differential incidence and prevalence of evolving cultural traits, as well as structure of endemic and epidemic features of society.

The use of epidemiological tools would have the advantage of allowing memetic research to proceed without making any ontological claims as to the nature or status of what exactly is being spread. Epidemiology is not the study of the inheritance of particular diseases or pathologies per se; rather it is the study of the distribution and pattern of the measurable effects of infection. Memetics qua social epidemiology might aspire to a similar goal. In the same way that causal mechanisms in the epidemiology of disease depend on, and vary with, the particular pathology that is being studied, taking the memetic stance does not require that social patterns be reduced to any one particular selective mechanism. Epidemiology may proceed independently of the aetiology of social products being researched; no assumptions about the heterogeneity or homogeneity of causal mechanisms are necessary.

7 Conclusion

The emerging paradigm of memetics and the established tradition of social contagion research do not simply have much to learn from each other, they are in fact two sides of the same social epidemiological coin, the former a theory-rich version of the latter, and the latter an evidence-rich version of the former. Taking the memetic stance is a radical move, but there are some wheels, particularly of the methodological variety, that just don't need to be reinvented by

memeticists, because they can already be found in social contagion research. Equally, memetics brings to the social contagion table an innovative conceptual framework with an important evolutionary component that the latter currently lacks. By integrating social contagion research and the memetic paradigm we would allow for the development a robust body of theoretically informed empirical research. In doing this we will be laying one more foundation for the long overdue Kuhnian paradigm shift that will finally see the integration of social science within a broader evolutionary paradigm.

A STRATEGY FOR MEMETICS: MEMES AS STRATEGIES
A Commentary on Gatherer's paper: Why the 'Thought Contagion' Metaphor is
Retarding the Progress of Memetic

By

Paul Marsden

PaulMarsden@msn.com

Gatherer's (1998) demolition tour of mental memetics and the thought contagion metaphor is convincing and is to be applauded. Memetics organised around the interactions of thought contagions (e.g. Lynch 1996, 1998) is problematic because that interaction is neither observable nor measurable. This simple fact renders the thought contagion metaphor both conceptually vacuous and empirically redundant. It is certainly not by performing arbitrary mathematical manipulations and endowing the objects of introspection with contagious properties that will improve the status of a partial and misleading metaphor.

As Gatherer notes, the thought contagion metaphor persists largely because of what could charitably be called a 'disregard' for linguistics and cognitive science. To this I would add a dangerous 'disregard' for the corpus of social science in general, *and evolutionary social science in particular* (Dietz, Burns and Buttel 1990, Flinn 1997, Durham 1990, Sanderson 1990, and Runciman 1998 provide good primers on this research area).

At least two further elementary points can be added to demonstrate why the thought contagion metaphor should be definitively buried. First, a 'thought' (if memeticists could ever isolate a single thought) has meaning, like a letter in a word, only by virtue of its specific position within an environmental context. Therefore, there can be no general laws of combination and permutation. Secondly, the essentialism implicit in the thought contagion metaphor is incompatible with the very selectionist paradigm within which memetics is grounded (Palmer and Donahue 1992).

Dawkins has recently declared that he is "alarmed" that his readers have taken his memetic speculations at face value as a theory of culture (Dawkins forthcoming). Dennett (1995, 1998), Plotkin (1997) and a number of leading evolutionary psychologists (e.g. Pinker 1998, Flinn 1997) have also made known their scepticism as to the scientific viability of the whole memetic enterprise. Of course, the fact that the founding fathers of memetics have doubts about memetics, qua scientific enterprise, is no reason in itself to abandon research. But surely we should be addressing their specific concerns, and those of other evolutionary theorists, rather than burying our heads in outmoded pseudoscientific introspectionism (see Rose 1998 and Clewley 1998 for an exposition of some of problems underlying these concerns).

A further more practical point, not underlined by Gatherer, is that meme theory built on the thought contagion metaphor is simply bad strategy for the establishment of memetics as a respectable and respected research enterprise. If memetics wishes to be taken seriously, it must first explicitly address the established theories that already seek to explain the object of

memetics' own enquiry and demonstrate *theoretically and empirically* how the new memetic approach is superior. Growing memetics in an intellectual vacuum on a staple diet of partial metaphors is not only foolhardy, it is intellectual suicide. An alternative and more successful strategy might be to emulate the one taken in the establishment of evolutionary psychology (e.g. Barkow, Cosmides and Tooby 1992) as a credible alternative to the Standard Social Scientific Model. Current paradigms were attacked and undermined, their weaknesses exposed, and then an alternative proposed which was then tested to demonstrate its utility.

For Gatherer, a viable strategy open to memetics would be a return to the 'Dawkins A' conceptualisation of a meme, and to adopt a research programme broadly similar to that of the established field of social contagion research. (Note that Gatherer is *not* advocating the rejection of the contagion part of the thought contagion metaphor, indeed there is a wealth of evidence supporting the behavioural contagion hypothesis; Marsden 1998b, 1998c, Levy and Nail 1993). In other words, by focusing on the epidemiology of behaviours, which would of course include verbal behaviour, Gatherer is advocating a reconceptualisation of memetics as behavioural ecology.

Whilst I agree with Gatherer's diagnosis, and whilst I also agree that memetics has much to learn methodologically from social contagion research (Marsden 1998b), I find his prescription for memetics ultimately unsatisfactory. It is not that there would be anything intrinsically wrong with such an approach, it is merely that it is difficult to see what it would offer in terms of increased understanding of the social world. Gatherer's approach would reduce memetics to an, albeit innovative, counting exercise. To be sure, if trends and correlations were to be identified over time, such an approach would have explanatory and predictive power, as I have previously shown elsewhere with the case of suicidal behaviour and media representations of suicide (Marsden 1998a). However, non-memetic research can generate the same correlations and predictions quite adequately without the application of the selectionist paradigm (e.g. Phillips 1980), and it is unclear what Gatherer's behavioural stance would add to these approaches. Further, whilst counting behaviours may be more scientific than counting thoughts, neither is particularly useful in a social world which is defined by structure and context.

Gatherer asks at the end of the 'focus' whether there is a viable third approach for memetics, to which I would reply in the affirmative. As I assume Lynch and Gatherer would agree, memetics involves the application of the selectionist paradigm to the sociocultural world. However, unlike Lynch and Gatherer, I maintain that the appropriate unit of analysis in this application should be neither the 'thought' nor the 'behaviour', but rather the *strategy*. A meme conceptualised as a culturally transmitted behavioural strategy has a number of advantages.

First of all, an approach characterised by a focus on the differential replication of strategies would allow for a more comprehensive memetic theory of culture. Social learning and socialisation cannot be reduced to localised imitative behaviour; strategies are copied and executed differentially across space and time. Replicating (conditional) strategies, rather than behaviours, could account for such differential and contextual behaviour (see Cloak 1975 and Cohen and Machelek 1988 for early attempts at such a project).

Secondly, by conceptualising memes in terms of functional and conditional strategies, a possible path between thorny methodological and ontological problems can be navigated. A strategy is an abstract concept, a heuristic device that (unlike thoughts) may be taken to link observable stimuli and responses. By focusing on the populational dynamics of strategy selection, memetics could leave open the question of how strategies are actually instantiated in the brain, yet still retain explanatory power and falsifiability by employing a methodological (as opposed to ontological) social behaviourist stance. All such an ontologically minimalist approach would involve would be the positing of a heuristic device (strategies) to explain and predict behaviour; this is what I call taking the memetic stance (Marsden 1998b).

Thirdly, meme theory thus conceived would allow for a theory of institutionalisation and structure emerging non-miraculously out of the reciprocal execution of strategies (see Burns and Dietz 1992 and Runciman 1998 for a similar approach). The reciprocal execution of strategies, by producing reciprocal action, would result in the establishment of practices and the foundations of institutions including, importantly, institutional power.

Further, by grounding memetics in the evolution of culturally transmitted behavioural strategies our enterprise could be a) conceptually integrated with behavioural ecology (e.g. Krebs and Davies 1981), b) draw usefully from evolutionary game theory (e.g. Maynard Smith 1993), and c) carve itself a legitimate and coherent investigative niche within the field of evolutionary theory.

Finally, by understanding the social self as web of memes, qua culturally transmitted behavioural strategies, meme theory may provide a useful non-reductionist alternative to a naïve folk psychological conceptualisation of social agency. The self could be deconstructed into networks of contextually dependent strategies that evolve according to the familiar evolutionary loop of variation replication and selection (Dennett 1991, 1998). Herein lies the exciting potential of memetics, a potential that is alas being retarded by the partial and ultimately vacuous metaphor of thought contagion.

Social contagion theory is not new. In fact, it has been an established explanation for the clustering and spread of human behaviour for nearly two centuries. In his classic study of suicide at the turn of the century, Emile Durkheim (1897) critically reviewed a century of 19th century contagion theory, from Lucas' *Imitation Contagieuse* to Despine's *Contagion Morale* to the then influential and contemporary theory of Tarde (1903). In another landmark study, Le Bon (1895) used contagion as the central mechanism to explain crowd behaviour, and Baldwin (1894) used the concept, *qua* imitation, as "... the law and the only law of the progressive interaction of the organism and its environment." (Baldwin 1894, p. 54) Both Bagehot (1869) and James (1880) provided an evolutionary dimension this ecological framework by arguing that differential propagation could be accounted for in terms of selection processes. Similar evolutionary-ecological approaches to culture were subsequently (re)-proposed and developed by various authors including Zipf (1935), Lovejoy (1936), Medawar (1959), Siegfried (1960), Sperry (1965) and Monod (1971). More recently, Dawkins (1976) coined the term meme - in preference to Zipf's *actemes* or Lovejoy's *unit-ideas* - to denote the unit of focus for such an approach.

The differential replication and selection of non-genetic information (culture) over *time* has been the specific focus of evolutionary epistemology (Popper 1974, Campbell 1974, Hull 1988, Plotkin 1982), whilst the differential replication of culture through both *space* and time has been the focus for contemporary innovation diffusion (Rogers 1995) and social contagion models (Levy and Nail 1993, Marsden 1998) of culture. The evolutionary-ecological approach today competes with rational choice theory as the most useful approach for understanding and predicting the spread of human behaviour.

Recently, a number of models exploring different aspects of the evolutionary dynamics and biases of culture have been developed under the broad umbrella of evolutionary culture theory (ECT). These include the coevolution model (Durham 1991), the dual inheritance model (Boyd and Richerson 1985), the cultural transmission model (Cavalli-Sforza and Feldman 1981), the gene-culture transmission model (Lumsden and Wilson 1981), the i-culture and m-culture model (Cloak 1975) and an emerging memetic model (Dawkins 1993, Dennett 1990, 1991, 1995, Plotkin 1994, Marsden 1998, Blackmore 1999).

Although ECT has tended to focus on the ideational aspect of culture, including the epidemiology of representations (Rindos 1985, 1986, Sperber 1994, 1996), a number of alternative conceptualisations of culture have been proposed, including those emphasising

behaviour (Langton 1979, Gatherer 1998), norms (Allison 1992), practices (Runciman 1998), rules (Burns and Dietz 1992) and strategies (Marsden 1999).

Enter Aaron Lynch's *Thought Contagion: How Belief Spreads Through Society: The New Science of Memes*, a book which I hoped would provide an accessible introduction, overview and perhaps an assessment of a part of this exciting emergent field. Lynch's express aim in the book was one of "putting memetics on more serious footing in the sciences". (P. vii)

Thought Contagion is accessible and entertaining, and it has two particular strengths. Firstly, it demonstrates clearly the memetic shift in focus from the internal cognitive processing of social agents, to the identification of patterns of cultural information transmission. Secondly, Lynch shows how such a framework or stance can be used to generate new sets of hypotheses which do not intuitively follow from traditional perspectives. In this way, Lynch does a good job of demonstrating how memetics could be used to generate a novel research programme that is both informed and guided theoretically.

However, Lynch's aim is severely handicapped by his decision to ignore over a century of ECT in particular and social science in general. Instead, Lynch declares that he independently reinvented memetics in 1978 (p. vii) and embarks on a confused and largely uninformed account of how, according to him, ideas about masturbation, breast fetishism, circumcision, psychoanalysis, abortion, firearms, dieting and crucifixion are supposed to spread through society.

In this exposition, Lynch draws on little besides Dawkins' "meme" label. He redefines memes somewhat mysteriously, and without elaboration, as "actively contagious ideas". (p. 2) A modicum of clarification is gained 148 pages later when he states: "Though not exactly a contagion of thought, the addiction to a specific drug can become a replicating brain condition, and hence a meme." (p. 150) Confused? Well, things get even more confusing when Lynch talks of 'ownership' as "a kind of "transcendental meme"" (p. 19) and focuses on what he calls thought contagions, a sort of sub genus of memes, which (we are told) are made up of memes that do not spread through "passive adaptation". (p. 25) For the reader who requires further clarification, Lynch points to an "extremely technical" journal article "filled with propagation diagrams and mathematical equations" on his home page at <<http://www.mcs.net/~aaron>>. I have read this paper and, perhaps because of my own shortcomings, I am no more enlightened. A review of this paper can be found in Gatherer (1998).

Lynch goes on to suggest seven modes of transmission (see Appendix) which are largely at odds with (and uninformed by) anything in ECT, social psychology or social science in general. Of these seven modes, Lynch focuses overwhelmingly on what he calls "quantity parental" and "efficiency parental" modes for his analysis. The reasoning goes something like this: Belief B causes the holder of B to have more children than average in a particular population. Given effective parental socialisation, this means that the children of the holder of B are more likely to hold B too, and thus the prevalence of B will increase with each generation. For example, Lynch suggests that a masturbation taboo may result in an increase in sexual intercourse, presumably to reduce frustration, producing an increase in fertility, which (given effective belief transmission down genetic lines of descent) results in more offspring inheriting the masturbation taboo. (If

you find this sort of reasoning too preposterous to swallow, see p. 4 and p. 90 to check it, and note that this is one of Lynch's more sensible, if unsubstantiated claims.)

The problems with this sort of reasoning are manifold and are indicative of the standard of argument throughout the book. Firstly, Lynch provides not one jot of evidence to substantiate the proposed correlation between masturbation taboo holders and fertility rates. In fact, the entire book is devoid of evidence which substantiates any of his wild speculations. Even if there were a correlation between the taboo holders and fertility, an elementary knowledge of social psychology should have suggested to Lynch that publicly expressed beliefs and private behaviour are often completely at odds with each other (LaPiere 1934). Beliefs and attitudes are generally rather poor predictors of behaviour and have been largely abandoned by predictive models in favour of intentions, within an overall logic of utility maximisation (Petty and Cacioppo 1981). So, for Lynch's central argument to hold, he would first have to show that holding a masturbation taboo was predictive of masturbation behaviour and then show that masturbation and fertility were inversely correlated. He does neither. Furthermore, Lynch's argument would only hold if there was evidence of this correlation **and** if effective parent to child belief transmission could be demonstrated. In the case of sexual mores and norms (which change radically between generations), it is naïve in the extreme simply to assume that this is the case. In fact, Lynch ignores the hugely important effect of belief transmission **between** genetic lines of descent, through schooling, peer groups, the mass media and other institutions. The net result of this approach is a tower of unsubstantiated supposition often producing quite incredible conclusions.

Why is the "man on top" sexual position so prevalent? "Memes placing the man on top during intercourse can also boost fertility by giving men more control of the rhythm and pace" (p. 93). This belief can thereby be transmitted to more children, increasing its relative frequency.

Why did the "domestic woman meme" spread? Lynch states (without a reference) that recent research has found a positive correlation between women's fertility and their fat-to-lean ratio. "Vigorous physical work" reduces the ratio and hence fertility, therefore this explains, according to Lynch, why domestic wives and the "domestic woman meme" spread through the population. (p. 55, p. 60)

Why does the "baby doll for girls meme" spread among girls? "Early practice with a doll might foster the gentle nurturing that helps females perform well as real mothers, too. This would also help the meme replicate into more surviving offspring, accounting for still more of its prevalence." (p. 57)

Why is circumcision so prevalent? "Instead, circumcision may have spread by raising reproductive rates. Circumcision eliminates the self-gliding capacity of the penis, channelling more lust (sic) to vaginal intercourse by limiting nonlubricated arousal methods. Activities ranging from masturbation to nearly vaginal sex (sic) become more difficult without an applied lubricant. In ancient times, the need for extra lubricants could have posed some challenge, leading couples to just go ahead and do it (sic) vaginally. The circumcision meme would therefore have flourished parentally." (p. 136)

Why do "breast privacy memes" spread? Breast feeding in private "disrupts the hormonal mechanism behind breast-feeding's contraceptive effects, raising reproductive rates for cultures that hide their breast feeding." (p. 137)

To be fair, Lynch does recognise other cases in which beliefs are transmitted *between* genetic lineages, and he introduces what perhaps is the most interesting concept in the book, that notion that thoughts have a specific "propagative profile" made up of the modes by which they are transmitted. Unfortunately, Lynch does not develop or exploit this theme, choosing instead to continue with a series of examples, including "girlish helplessness" and "family-man finder" memes that challenge the credibility of the book. For example:

What memes deter homosexual behaviour? "For instance, the belief that male homosexuality requires anal sex deters homosexual mating in those males who dread anal sex." (p. 84)

Why do socialistic ideas spread? "... people with little property may expect personal gain by spreading socialist or communist beliefs." (p. 20)

Why is the breast fetish meme so prevalent? "Homosexuality and its taboo affect the "fashionability" of certain sexual fetishes in heterosexual males. Specifically, a "mandatory breast fetish" meme evolves and spreads ..." By verbalising attraction to breasts, men "... imply their exclusive heterosexuality." (p. 85)

Why might progun memes spread better than antigun memes? "Fiercely progun memes can also intimidate hosts of gun-control memes into silence ..." because "Most antigun folks would probably assume that fiercely progun people own firearms and might use them if angered. Yet few people worry about being shot by an angry gun-control advocate." (p. 163)

Why does the family home meme spread? The family home meme means that "... dependent homemakers, in particular, will worry less that a highly employable husband would depart for a new job and a new life far away." (p. 51)

Why does the big house meme spread? "The more money a couple spends on joint real estate, the more confident they can feel in each other's commitment to stay settled together. Extra children resulting from this mutual confidence can partly explain the proliferation of plans to buy as large a house as the income allows." (p. 51)

Now there is nothing wrong in using a memetic or any other framework to generate hypotheses, however wild, but they are of no value until evidence is provided to support them. But even in the absence of evidence, Lynch's speculations seem to be devoid of any rationale. For example:

Why do men talk more about/prefer women's breasts than posteriors? "Indeed, young males may feel inhibited from discussing female posteriors because it reminds them of anal sex and homosexuality ..." (p. 86)

Why is masturbation "prime material for commercial use"? Masturbation is a "prime material for commercial use" because it can make "... people pay attention long enough to hear a

commercial, and then improve recall of the commercial by "downloading" it to an aroused audience." (p. 91)

Why do women want to have children? "As the girl grows up, she learns that she is too old to play with dolls anymore. But the desire for comfort and attachment remains, and translates into a desire for a real baby". This is what lies behind the phenomenon of "baby lust". (p. 57)

The problem I have with all this uninformed speculation is not that there is the slightest risk that anybody could possibly take it seriously, but rather that it might be construed as representative of work that is being done in ECT and memetics, because it is not. Fortunately, suspicion is likely to be aroused in even the most uninitiated reader when Lynch includes a discussion of the science fictional "psychohistory" in his brief misrepresentation of the various social sciences, in the process of claiming that his brand of memetics is "the missing link".

I have argued elsewhere (Marsden 1999), as have others (Gatherer 1998, Flinn 1997) that, when taken literally as Lynch does, the thought contagion metaphor is quite disingenuous. I will not repeat the arguments here, suffice it to say that even if thoughts are anything other than a heuristic description in folk psychology, we know nothing about how they combine or recombine and it is certainly not ignoring cognitive processing and endowing thoughts with contagious properties that makes the memetic approach any more viable. When Lynch conflates the partial metaphor of thought contagion with population genetics by arguing that "Population memetics is the study of how proliferating memes combine and separate in a population", which "roughly parallels" population genetics (p. 12), his whole approach becomes even more confused.

What, for example, is it about the "mandatory breast fetish meme" that qualifies it as a meme? Just in what sense is it "actively contagious"? Or how is it a replicating brain condition? We know that folk psychological concepts do not match specific brain states; there is no breast fetish brain neuron or state that replicates and is identical across different brains. How does this meme recombine and perhaps then separate from a 'non mandatory nipple revulsion meme'? If they actually exist at all, thoughts and their 'meanings' are certainly contextually and subjectively dependent (Heyes *et al.* 1993, *passim*), and this fact alone strongly suggests that there can be no *laws* of combination and separation.

Does *Thought Contagion* demonstrate that an epidemiological or evolutionary-ecological approach to understanding non-genetically transmitted information (culture) is ultimately redundant, vacuous or false? The answer, I suggest, is no simply because exposure to culturally transmitted information clearly does influence the likelihood of an agent (re)-transmitting the information in that or another form. Call it social, vicarious or observational learning, replication or imitation, the fact is that our behavioural strategies are in part determined by the behavioural strategies of those around us. (See Marsden 1998 for a review.) From this simple observation, it is possible to adopt an alternative stance, a memetic stance, for interpreting, understanding, explaining and predicting human behaviour. Just as it is possible to interpret human behaviour *as if* it emanates from a homuncular centre of intentionality, our propensity to copy behavioural strategies, and the behavioural clustering that results, means that it is sometimes useful to understand non-genetic information transmission *as if* it were a contagion. By this, all I mean is

that our production of behaviour is sometimes dependent on the extensity and intensity of our exposure to that behaviour, or at least some representation of that behaviour.

By understanding the social agent as differentially selecting and replicating the information it is exposed to, models such as the Bass equation (Bass 1969) can be used to predict and model the spread of behaviours and products through a population without invoking or relying on homuncular folk psychology. Such an approach does not ignore cognitive processing, it simply shifts the focus to the description of how one subset of non-genetically transmitted input information is *selected* for output over another.

Of course, social agents do not blindly and directly imitate all the strategies they are exposed to, as in a simple game of Tit For Tat. Replication is altogether more sophisticated, temporally and contextually cued, and critically, involving the selection of one strategy instead of another. We are highly discriminating and discerning imitators. Indeed, the evolved structure of our brains has produced a remarkable intentional system out of our learning capacities such that we can usually view our behaviour as if it were produced by a principle of utility maximisation. Social agents are pretty good control systems, selecting various strategies to attain antecedently fixed ends.

However, the frame problem precludes optimality in this utility maximisation process, and this means that the intentional stance sometimes breaks down - we sometimes seem to behave irrationally. This, I suggest, is where memetics may be useful. Just as evolutionary psychologists may focus on how *biases* in strategy selection might result from the evolved cognitive architecture of our brains, memetics might inform us of how the differential exposure to culture influences strategy selection. Just as the evolved architecture of the brain may produce an intentional system with certain biases towards inclusive genetic fitness enhancement (within the environment of evolutionary adaptedness), a memetic stance might legitimately invoke an analogous heuristic of *inclusive memetic fitness enhancement* (within a particular context) to explain non-rational strategy selection. Because differential exposure to stimuli impacts upon how we respond to situations (by increasing the likelihood of replicating that stimuli), the trajectory and evolution of cultural information through a cultural environment will appear as if the information "wants to get itself" replicated.

The principle of inclusive memetic fitness enhancement is simply a heuristic (as opposed to an ontological) claim for interpreting the production of culture as if it were an attempt to enhance the survival chances of that culture, that is, as if the culture itself had a rudimentary intentionality. Crudely speaking, rather than always behave selfishly for what I personally may want (whatever that may mean), I will fight for my ideas and help others who share my ideas. Just as I may lay down my life for more than 2 brothers or more than 8 first cousins, I might also lay down my life for more than 2 brothers in arms, or more than 8 individuals with whom I share more than an eighth of my culture. Note that this memetic stance is neither incompatible with the intentional stance, nor with folk psychology; it simply provides a different stance for analysing human interaction, one that adumbrates certain features of culture and clarifies others. In sum, what I am proposing is that the memetic stance may provide a useful heuristic for interpreting non-rational behaviour, i.e. when the intentional stance breaks down. This memetic stance of course needs to be tested, but if it turns out to be useful in modelling and predicting behaviour,

integrating it with its sociobiological counterpart may one day provide a real alternative to homuncular folk psychology.

Theorists often speak in terms of architecture. They describe their work in terms of constructing theoretical edifices and laying theoretical foundations. This is useful language, it highlights the laborious step by step nature of theory building, where each move forward, whilst a tentative and speculative move into the dark, is both theoretically and empirically informed by what has gone before it, and is designed so as to be open to testing. If Aaron Lynch's intention in writing *Thought Contagion* was to put memetics on more serious footing in the sciences, in this he must be seen to have failed quite spectacularly. Fortunately, memetics has somewhat more secure foundations, as exemplified in the recent publication of Sue Blackmore's *The Meme Machine* (Blackmore 1999), which I commend to you as a useful contribution to ECT.

Appendix: Lynch's Seven Modes of Memetic Transmission

"Quantity Parental" - Have lots of children and use your position of authority to indoctrinate them and increase the prevalence of your beliefs.

"Efficiency parental" - Propagate the belief that parents are good sources of indoctrination, then have lots of children and use your position of authority to further indoctrinate them and increase the prevalence of your beliefs.

"Proselytic" - Convince your non-kin that your belief is both right and urgent so that they will spread it for you. Lynch uses the example of appeals to fear. A belief that spreads will spread ...

"Preservational" - Ideas that protect your ideas from being challenged, such as the belief that one should never talk about religion or politics in polite company.

"Adversative" - A belief involving "selectively killing those who refuse to convert" to your beliefs, or at least sabotaging alternative beliefs. "The Muslim belief" is cited as an example of the adversative mode.

"Cognitive Advantage" - Make sure your belief appears "well founded" and it will tend to spread.

"Motivational" - Make your idea a good idea and it will tend to spread.

FOREFATHERS OF MEMETICS: GABRIEL TARDE AND THE LAWS OF IMITATION

By

Paul Marsden

Graduate Research Centre in the Social Sciences

University of Sussex

PaulMarsden@msn.com

"Meanwhile, let us not forget that every invention and every discovery consists of the interference in somebody's mind of certain old pieces of information that have generally been handed down by others. What did Darwin's thesis about natural selection amount to? To have proclaimed the fact of competition among living things? No, but in having for the first time combined this idea with the ideas of variability and heredity. The former idea, as it was proclaimed by Aristotle, remained sterile until it was associated with the two latter ideas. From that as a starting point, we may say that the generic term, of which inventions is but a species, is the fruitful interference of repetitions."

Gabriel Tarde, *The Laws of Imitation* p.382

One way to conceptualise memetics is as a stance that seeks, using a selectionist rationale, to interpret the human social world in terms of the ongoing differential reproduction of traits describing that social world (Marsden 1999). Reproduction in the social world may occur at many levels; objectified individual acts are replicable and can become typified and habitual, thereby becoming practices, themselves reproducible, and through typified reciprocal interaction, institutions can emerge with roles that serve their own propagation (cf. Price and Shaw 1998). Through this multi-level sociological dance of reproduction, we both produce and are produced by the social world. The idea is that by employing a selectionist rationale, essentially the Law of Effect and perhaps a heuristic of inclusive memetic fitness, memetics may come to provide some purchase on how acts, practices and institutions provide for their own self-emplacement in a world where the products of variation outnumber the capacity for subsequent selection and reproduction.

Such a memetic research focus is not, however, without precedent; a century ago, one of the founding fathers of sociology, Gabriel Tarde, outlined a programme for sociology in his treatise, *Les Lois de l'Imitation* that has much in common with this memetic project (The Laws of Imitation 1890, translated 1903, reprinted in English 1962 to which page references here refer). The purpose of this short research note is to familiarise those participating in the construction of a memetic perspective with Tarde's model, a model that certainly has historical significance for contemporary memetics and possibly theoretical significance as well.

Gabriel Tarde was born in Sarlat, the Dordogne, France in 1843 where he grew up to become a lawyer and juge d'instruction. Early on in his career, he observed that particular crimes appeared to spread in waves through society as if they were fashions. Becoming increasingly interested with how this epidemiological aspect of criminal activity might be just one instance of a more general feature of the social world, Tarde published a number of papers in the *Revue*

Philosophique between 1880 and 1901, including a paper entitled, "Darwinisme naturel et Darwinisme social" (Tarde 1884) which developed this idea and outlined a general research programme for sociology.

Basically, what Tarde proposed was a different way of looking at the social world, not from the perspective of the individual or the group, but from the point of view of the products, acts and ideas that were used to classify those individuals or groups. By focusing on how these features were differentially reproduced, Tarde suggested it was possible to infer certain regularities or laws that appeared to pattern the social world. In 1890, he presented his arguments along with a preliminary set of "laws" in his major work, *Les Lois de l'imitation*, and in doing so provided researchers with model for interpreting the social world. The key point of distinction of Tarde's model, over other emerging sociological models such as the structural sociology of his compatriot Emile Durkheim, was that social organisation and the social relations describing that organisation were understood as a means for the more ultimate goal of propagation.

"Self-propagation and not self-organisation is the prime demand of the social as well as of the vital thing. Organisation is but the means of which propagation, of which generative or imitative imitation, is the end." Tarde 1903/1962: 74

By 'generative imitation', Tarde referred to a process of invention that he conceptualised in terms of the combination of existing imitations, that is, the "fruitful interference of repetitions", whilst he used the term 'imitative imitation' to denote the propagation of inventions and their imitations across time and space. It should be clear that such an inclusive understanding of imitation as denoting general products and processes of repetition in the social world is very different from the more restrictive use of the term adopted by some meme theorists (e.g. Blackmore 1998) who, following comparative psychologists, employ the term to denote only acts socially learned by observation that are then performed. Rather, Tarde wished to stretch the already more inclusive meaning of the French word imitation and imbibe it with a deeper meaning to refer to the general class of objects that were reproduced in society and the various processes that were instrumental in their reproduction, "whether willed or not willed, passive or active" (xiv).

Tarde's basic argument was that human history could be usefully interpreted as a "career" of imitations, trajectories of inherited inventions through populations that differentially survive an ongoing culling process of "counter-imitation", that is, rejection (154).

"All resemblances of social origin in society are the direct or indirect fruit of the various forms of imitation, - custom-imitation or fashion-imitation, sympathy-imitation or obedience-imitation, precept-imitation or education-imitation, native imitation, deliberate imitation, etc. In this lies the excellence of the contemporaneous method of explaining doctrines and institutions through their history. It is a method that is certain to come into more general use." (14)

So central and universal to the human condition was imitation thus conceived for Tarde that he went so far as to suggest that society itself could be defined as imitation insofar as societies could be described in terms of populations of individuals with common imitated traits who are apt to share imitations (68)

"What is society? I have answered: Society is imitation". (74).

The primary task of Tarde's proposed sociology was to identify the variables that appeared to influence whether an object of imitation would become successful, that is, get reproduced, in order to explain how some imitations came to be selected over others (110-111).

"Our problem is to learn why, given one hundred different innovations conceived of at the same time - innovations in the form of words, in mythical ideas, in industrial processes etc. - ten will spread abroad, while ninety will be forgotten." (140)

Tarde's answer to this question was to propose a number of general laws that seemed to pattern the differential reproduction of imitations, which he divided into those that had an apparent logical quality, and those of an extra-logical or less rational nature. Specifically, the "logical laws of imitation" (140-188) proposed by Tarde were that:

The origination of an invention involves the recombination of existing imitations, and this origination will be influenced by the social context and abilities of those involved with the recombination.

The success of an imitation in spreading geometrically from its point of origination will be a function of its fit, that is, compatibility, with the environment of existing imitations.

The selection, that is, adoption of an imitation occurs either through "substitution" involving a "logical dual" and "struggle" between two alternatives, or through "accumulation", a process entailing a logical union of imitations.

Tarde also noted that it was important to understand the success of competing imitations as a function of the power held by those with vested interests in the reproduction of those imitations (169). Although, he did not couch it in such terms, I have suggested that this insight may provide a useful rationale for interpreting the differential propagation of imitations in terms of relations to the means of reproduction (Marsden 1998).

Tarde's principal "extra-logical influences" (189-365) stated the following:

The reproduction of ends generally precedes the reproduction of the means to those ends (194-213). In other words, in Tarde's view, goals tend to be imitated before the actions that serve to attain them are adopted. For example, the imitation of a goal, say to become rich, will generally antecede the adoption of imitations employed to further this goal.

Imitations tend to propagate through a process of stratified diffusion from those perceived as superior to those who perceive them as superior (213-243). For example, traits originally associated with celebrities and otherwise privileged tend to trickle down to those who associate them with such traits.

Tarde also made several observations pertaining to what he suggested were general tendencies in the spread and selection of imitations. For instance, he suggested that in democratic populations

the voice of public opinion increasingly becomes the authority whose example is copied, whilst traditional and expert authority wanes (229). Similarly, he proposed that imitative activity, including generative imitation, tends to be proportional to population density (239), thereby allowing for the faster spread and development of imitations in cities than rural areas. Additionally, Tarde noted a general shift in the mode of social reproduction from custom, that is, endemic horizontal transmission, to fashion - epidemic horizontal transmission (244-255).

In an observation that would be at home with Brodie's memetic reconceptualisation of social influence literature (Brodie 1996), Tarde also raised the possibility of engineering a successful imitation independently of any truth or utility that imitation may have. To engineer a successful imitation, or meme in today's parlance, Tarde suggested that it might suffice to present the invention (mutant imitation) as a descendent of an endemic part of culture into which it is to be introduced:

"...assume the mask of the enemy and besiege existing custom by unearthing some ancient custom long since fallen into discredit and rejuvenated for the needs of her cause..." (261)

Although Tarde's proposed research programme was somewhat eclipsed in sociology by Durkheim's more structural approach, his work comprising over 5000 published pages (Clark 1969) became the inspiration for innovation adoption research in applied sociology, particularly rural sociology (Ryan and Gross 1943) and medical sociology (Katz 1961). Likewise, Tarde's model underpins much that passes for diffusion research in marketing (Bass 1969, Rogers 1995), whilst in psychology his framework influenced the thinking of Baldwin (1894) and more indirectly Mead (1934).

For researchers in memetics, any potential contribution of Tarde has yet to be realised, but it is hoped that this brief introduction to one of the forefathers of memetics might serve as a creative stimulus for the 'generative imitation' that will come to define our enterprise.

IS SUICIDE CONTAGIOUS? A CASE STUDY IN APPLIED MEMETICS

By

Paul Marsden

Visiting Research Fellow

Graduate Research Centre in the Social Sciences

University of Sussex

paul@viralculture.com

Abstract

The phenomenon of suicide contagion is demonstrated experimentally. An interpretation of the results is proposed using an understanding of *memetics as contagion psychology informed by selectionist thinking*. Using the term 'meme' to denote an object of contagion and 'contagion' to denote a process of spread by exposure, a selectionist explanation of why certain people might be susceptible to a contagion of suicide is provided. Specifically, it is suggested that people who have become socially isolated and culturally disenfranchised, i.e. those with reduced residual cultural fitness (compromised access to the means of cultural reproduction), might be at particular risk from suicide contagion. Finally, public health policy implications of this memetic understanding of suicide are briefly outlined.

1 Introduction

In June 1962, the managers of a textile factory in Strongsville, USA, were obliged to close down their factory because of a 'mysterious sickness' that was affecting onsite workers.

On the evening of the closure, a news report described how at least ten women and one man had been admitted to hospital suffering from rashes and severe nausea. The news report also suggested that the cause of the sickness was a poisonous bite from an insect that had arrived in a shipment from England, and had taken up residence in the factory.

Several weeks later, with the plant still closed, a total of 62 workers had sought medical attention, having developed the symptoms of having been bitten by the bug. From initial rashes and nausea, the effects of the poisonous bite appeared to develop into chronic severe weakness punctuated with acute panic attacks.

The US Public Health Service 'Communicable Disease Center' with a team of entomologists was called in to investigate this 'June Bug', and took the expensive decision to fumigate and vacuum the huge textile plant.

After careful investigation, it was concluded that there had been no dangerous bug at all, English or otherwise. Rather, the episode had been an example of a process that social psychologists call 'social contagion', a generic label used to describe the apparent infectious spread of opinions, emotions and behaviour by exposure to similar opinions, emotions or behaviours.

Social contagion usually occurs in contexts of uncertainty and stress, where people make use of information in the actions of people around them to make sense of situations, resolve ambiguity and to inform their own responses (Colligan, Pennebaker and Murphy 1982). Sure enough, when two social psychologists, Kerckhoff and Back (1968), interviewed victims of the mysterious 'June Bug' illness they found that those who had been 'bitten' had been suffering from undiagnosed stress and alienation.

2 Memetics and Social Contagion: Two Sides of the Same Coin

I have argued in a previous paper that for applied memetics, an inclusive and pragmatic working definition of a meme is *the object of contagion* (Marsden 1998a). This is consistent with the popular understanding of memetics as the study of 'infectious' elements of culture. By 'infectious', what is meant is the quality of some acts, emotions and opinions, in certain contexts, to spread by exposure rather than by some deliberate attempt to influence (such as coercion or persuasion).

The purpose of this paper is not to engage in an abstract discussion of the merits of this or that conception of a meme or memetics; indeed the purpose of using the meme neologism to describe objects of contagion is wholly pragmatic; *to provide a rich, substantive research focus, and get on with doing memetics*. Interestingly, contagion psychology shows that a meme, thus conceived, may have no essential properties, and is always a meme in context, thereby defying useful abstract discussion. For example, an act may spread by exposure in one context (and thus be a meme), but spread by coercion in another (and therefore not be a meme). Of course, if the term 'meme' is used as a scientific-sounding basket label for all received ideas or socially learned behaviours, then the notion of a meme as an object of contagion, and *memetics as a selectionist interpretation of contagion psychology*, may seem unnecessarily restrictive. However, the advantage of the more modest conception of memetics is that it is useful *within* established social scientific models of human psychology, instead of being of interest only from *without*.

What follows is an example of how applied memetics might usefully proceed based on this understanding of a meme as an object of contagion, focusing on the peculiar phenomenon of suicide contagion.

3 Suicide Contagion - Infected by a Suicide Meme

Suicide contagion is said to occur when exposure to suicidal acts appears to trigger copycat suicidal acts. This peculiar phenomenon challenges rational interpretation perhaps as much as the notion of suicide, that is, deliberate self-destruction, itself. Now, sense can be made of many memetic phenomena within an established social learning framework; that we use information vicariously available to us in other people's experiences to inform our own adaptive responses to ambiguous situations. However, suicide contagion does not seem to fit this model insofar as suicide is clearly not adaptive from the suicidal individual's point of view. So bizarre is the phenomenon, that despite the consistent finding of elevated suicide levels following suicide publicity (Marsden 1998b), some researchers find the whole idea of suicide contagion incredible. Nevertheless, strict official guidelines do exist on how suicide should be publicly discussed (e.g. CDC 1994) based on the assumption that individuals contemplating suicide who see suicide or

suicidal individuals rewarded (in attention and/or positive evaluation) may infer that suicide is an appropriate response to their distress.

The suicide contagion hypothesis is that exposure to suicide is a suicide risk-factor for people experiencing an unresolved conflict as to whether suicide is an appropriate response to current unresolved distress. Whilst ethical considerations obviously preclude the direct experimental investigation of this hypothesis, one aspect of suicide contagion does lend itself to indirect experimental research. This is the impact of semantic priming.

4 Priming your Mind with Suicide

Priming refers to the idea that the interpretation of situations can be involuntarily patterned by recent and frequently experienced events (Fiske and Taylor 1991). To take a trivial example, a habitual walk home after seeing a frightening movie may result in an increased level of 'feeling spooked' because the themes evoked by the film remain salient in the mind, thereby producing contagion; the spookiness of the movie influences subsequent interpretations of events. More generally, priming suggests that the ways in which situations are interpreted can be influenced by ideas salient in memory that have been the focus of recent and/or frequent attention. Put simply, we tend to use the meanings we have to hand in interpreting situations. Further, because some ideas cue other ideas, this aspect of what is known as social cognition may result in 'spreading activation' whereby exposure to ideas cue not only those ideas but also related ideas.

"Thoughts of which one is consciously aware send out radiating activation along associative pathways, thereby activating other related thoughts. In this way, ideas about aggression that are not identical to those observed in the media may be elicited later. In addition, thoughts are linked, along the same sort of associative lines, not only to other thoughts but also to emotional reactions and behavioural tendencies." (Geen and Thomas 1986: 12)

For example, in one experiment it was found that people became more aggressive following exposure to images of weapons, as aggressive ideas around weapons were primed in the mind of the exposed to them (Leyens and Parke 1975). The idea is that when activated by becoming the focus of attention, a concept and related concepts in the semantic network of an individual's memory are easier to retrieve, that is, the mind is primed with these concepts and will tend to use them to interpret situations (Higgins 1989, Fiske and Taylor 1991, Berkowitz 1984, Jo and Berkowitz 1994).

Applied to suicide contagion, this interpretation would predict that exposure to suicide should have a short-term impact on how a situation is interpreted as being potentially suicidal. To test the plausibility of this model, the following experiment was conducted as part of a D.Phil research project in 1999 (Marsden 2000).

5 Testing the Model - Is Suicide Contagious?

5.1 Research Objectives

To assess the empirical plausibility of the idea of suicide contagion by priming; specifically that mediate exposure over the Internet to the concept of suicide can influence how a situation is subsequently interpreted as being potentially suicidal.

Specifically, the research hypothesis was as follows:

Priming participants with the idea of suicide, by informing them that the topic of research was 'young people and suicide', would result in an increased likelihood of interpreting a distressing and ambiguous situation described by a text as suicidal

5.2 Materials and Method

Standard experimental design of controlled exposure to the concept of suicide over the web was followed by data capture in a self-completion web questionnaire. Piloted in April 1999, the research took place in May 1999. Participants were randomly assigned to either an experimental group or a control group, all invited to first read a short text about a distressed student at university, and then indicate on a standard 5-point Likert scale, the likelihood that they thought that the student would commit suicide (1 = not at all likely, 5 = very likely). The only difference in materials used between the two groups was how the research study was introduced to them; in the experimental group the welcome screen introduced the study by saying that it was about young people and suicide, and in the control group about young people and stress. The texts and HTML questionnaires were published to the Internet at using Microsoft FrontPage and a custom CGI script that randomly directed participants from an initial index welcome page to one of the two texts. The responses were captured in a simple CSV (comma separated variable) database sent from the HTML form.

5.3 Participants and Recruitment

Participants were UK Internet-users over the age of 18 recruited through chain email. Because of the potentially sensitive nature of the research, no incentives were offered, and instructions were given to those recommending individuals that only those over eighteen should be invited. Additionally, attention was called to a hyperlink provided on each page of the web questionnaire to an online support group, (Samaritans - although this was unnamed) to be used if participants found the exercise in any way distressing. Finally, participants were told that they could change their mind about participating, and withdraw from the exercise at any time.

5.4 Results

67 UK Internet-users completed the task (36 male, 31 female, average age 22) over a two-week period in May 1999. The research hypotheses predicted that participants primed with the concept of suicide would be more likely to assess an ambiguous situation as more suicidal than participants not primed with the concept of suicide. An inspection of the mean results was

consistent with this, with those primed with suicide interpreting the likelihood that a distressed individual would commit suicide at 2.42, and this compared to 1.77 in the control group. A one-way ANOVA (analysis of variance) revealed that this difference was statistically significant at the 0.001 level ($F(1,65) = 11.79, p < .001$) indicating a strong patterning of the data in a way consistent with expectations of the model.

Figure 1: Suicide is Contagious

5.5 Discussion

The results of this study were consistent with the idea that exposure to the idea of suicide can prime the concept of suicide in peoples' minds and influence the interpretation of ambiguous situations by facilitating a perception of that situation as suicidal. Although the research hypothesis was confirmed by a strong patterning of the data, thus suggestive of such an influence for the group of participating adult UK Internet-users, the use of non-probability sampling would have precluded any possibility of generalising the results to a more general UK Internet-user population, even if this were considered a legitimate strategy. Further, although the results were continuous with expectations following from the model in terms of interpreting somebody else's situation as suicidal, this does not imply, other than extremely weakly, that participants might also be more likely to interpret their own situations as suicidal following exposure to suicide. Nevertheless, the results of this small study are consistent with such a view.

6 But is this Memetics?

The above experiment is a simple example of applied memetics operationalised as the study of infectious acts, opinions and emotions. Now, the critic could argue that this understanding of

memetics adds little to the already established field of social contagion research, apart from providing a useful label for the object of contagion. However, from the understanding of memetics proposed here, this is not a problem because memetic research is social contagion research.

Further, it may be possible to gain some leverage from the selectionist heritage that underpins Dawkins' neologism, and use it as a creative stimulus for generating hypotheses on why certain people appear to be susceptible to contagion. By way of example, I would like to conclude by proposing a selectionist understanding of why certain people, and not others, may be susceptible to suicide in general and suicide contagion in particular.

As noted above, suicide is problematic because it is clearly not an adaptive act from the perspective of the suicidal individual. This has led some to suggest that suicide might be enabled by a heritable genetic variation that remains in the gene pool over time because it enables suicide when the residual inclusive fitness of an individual is particularly low (e.g. de Catanzaro 1980, 1981).

Whilst a genetic 'enablement' of suicide may well be feasible, it is possible to apply an alternative cultural model using a similar logic. Specifically, if cultural variations, such as those that enable suicide, persist based on their likelihood of being adopted, then the inclusion of suicide in a culture as a meme is only viable over time if it has no systematically deleterious effect on its own reproduction. Now, one way that this could be possible is if those committing suicide were not significant contributors to the propagation of suicide themselves, so that their deaths would not negatively impact on the persistence of suicide. It is this point that provides a selectionist hypothesis for susceptibility to suicide contagion insofar as such susceptibility might be contingent on a reduced residual capacity to pass on culture. In such cases, suicide would not be maladaptive, because the suicidal individual would not be culturally 'viable'.

This model leads to an empirical prediction pertaining to those most at risk from suicide contagion. The model would predict that those susceptible to suicide contagion should be those with a reduced residual capacity to spread culture, that is, those who become socially isolated and culturally disenfranchised. Indeed, over and above the possibility that suicide may be used as a strategy for increasing a waning cultural fitness, the fact that cultures are shared means that the suicide of those whose capacity to reproduce their culture has become compromised could actually increase the overall capacity of cultural relatives to pass on shared culture, including any suicide meme. In fact, if an individual actually represented a cost to the overall reproductive potential of the shared culture to which suicide is a part, then suicide could actually have a positive effect on the likelihood that that some 'suicide culture' gets reproduced. In this model, differential ownership of the means of cultural reproduction, or simply put, marginality, would be a key variable in susceptibility to suicide contagion, and to suicide in general.

This memetic prediction is borne out by empirical research that has consistently demonstrated that low levels of social cohesion are one of the most significant risk factors in suicide (e.g. Durkheim 1970 [1897], Halbwachs 1978 [1930], Henry and Short 1954, Gibbs and Martin 1964, Maris 1981). In these cases, suicide contagion could be seen as a 'fortuitous' cultural mutation

that allows a culture to effectively rid itself of parasites that reduce its reproductive potential to maintain itself.

The tentative support for this memetic model might warrant formalisation for future research using, for instance, Hamilton's (1964) model of inclusive fitness in a cultural substrate. Specifically, as long as overall inclusive capacity of the set of culture that describes an individual is not reduced by suicide (or indeed self-sacrifice, as in the case of war), then any suggestion-by-exposure to suicide occurring within a constellation of pro-suicidal circumstances could be more likely to result in suicide. This is because the benefit of suicide to cultural relatives, in terms of enhancing their capacity to reproduce their shared culture multiplied by a degree of cultural relatedness to the suicidal individual, would be equal or superior to the direct cost to the suicidal individual of suicide in terms of any personal capacity to make such contributions.

Memetic Model of Suicide
$C_d < rB_r$

Figure 2: Hamilton's Rule for the Biological Communication of the Individually Maladaptive Traits. Here: C_d = Cost in cultural reproductive potential of suicide to individual, r = coefficient of relatedness, and B_r = Benefit in cultural reproductive potential of suicide to cultural relatives

With respect to practical public policy recommendations on reducing contagion, this interpretation provides an argument for curtailing any sensationalist media publicity around suicide, because such publicity might effectively increase the cultural fitness of the suicidal individual, that is, the capacity to pass on culture. Rather than merely refrain from the positive portrayal of suicide and suicide victims in the media as per current recommendations, this memetic model of suicide could be used to suggest that there could be a potential benefit (if reducing suicide levels is seen as beneficial) of not covering suicides stories at all, or at least reporting the deaths but not as suicides. Of course, there are important and controversial issues of censorship and free speech that are raised here, and it may be decided that suicide contagion is a lesser evil than what amounts to ideational eugenics.

7 Conclusion

This paper presents one vision of memetics, as an integrated part of applied social science investigating substantive issues of human experience. Understanding memetics as contagion psychology, using selectionist thinking to inform interpretation, is certainly not the only way to conceptualise the nascent discipline, but it is hoped that it is one that will allow memetics, after a quarter of a century of discussion, to start providing useful insight into real-world issues and problems.

THE INTERNET AND MEMETICS

By

Garry Marshall

School of Computing Science, Middlesex University, Trent Park, Bramley Road, London N14

4XS, England.

e-mail: Garry2@mdx.ac.uk

Abstract

The functioning and usage of the Internet are examined in terms of memes and memetics. It is shown that memetic systems can be distinguished at various levels of Internet operation, and that these systems become increasingly simple as they move further from the user level. In this way, memetics provides a unified framework for examining the overall behaviour of the Internet and its users.

1. Introduction

Memetics provides a powerful new way to think about things such as, for example, creativity (Gabora, 1997). The aim of this paper is to use memetics as the basis for obtaining a better understanding of the Internet both in its operation and in the way it is used. A primary purpose of a network such as the Internet is to support communication. In this role, and especially as a carrier of e-mail messages, it serves to disperse memes, spreading them across the network rapidly and accurately. Recently, the principal use of the Internet has moved from e-mail to the World Wide Web. While e-mail is still widely used, the move to the World Wide Web has caused a shift in emphasis from carrying messages to the storage of interconnected documents (Heylighen, 1996). The results of this change are, among others, to ensure the longevity of memes and to link together related memes. The consequence of the availability of both e-mail and the World Wide Web is that the Internet is, for its users, an ideal medium for the spread, replication and storage of memes.

The Internet, like all computer networks, is designed and constructed in a layered fashion, with layers of software added to the basic hardware. The layering facilitates the synthesis of a complex and complicated system but it has always been difficult to describe the operation of the layers in a consistent way so that the activities in one layer could be related directly to those in another. More importantly, the basic rationale for layering is to facilitate meta-system construction, but it has never been entirely clear that this has been achieved in any coherent way. In any event, if a major purpose of the network is to communicate and store memes, one would expect to find memetic ideas present in its design and implementation, even though its designers may not have called on them explicitly.

In fact, as this paper shows in a limited way, the functioning of the various layers can be interpreted memetically. Such an interpretation is of value not only in linking the purpose and operation of the network but also in showing the extent to which the memetic processes the network is intended to support map onto the memetic processes carried out by the underlying

layers. A clear and direct mapping will indicate a well designed network, whereas the absence of any direct mapping will not only indicate shortcomings and inefficiencies in the way that the network operates but also help to identify their causes. This paper, then, is an attempt to expose the memetic systems and processes occurring at different levels of Internet operation. It also shows how the processes in adjacent layers relate to one another which, in turn, exposes the meta-system transitions.

2. Memetics at the operational level

We begin by considering the World Wide Web. Here, a system of connections, or links, is maintained in a data space so that the space can be navigated. But this data space, as with everything else on the Internet, is supported by the underlying network, and the connections of the network do not correspond directly to the connections of the data space. To ensure that the users of the virtual world provided by the data space are unaware of the underlying network, any connection that is to be followed in the data space must automatically be mapped onto a route in the network. This means that routing is an aspect of network operation that is vital to the success of the World Wide Web, just as it is for other Internet services.

Routing is, in essence, achieved with routing tables. Each node of the network has a routing table that determines from the destination of a message how that message should be forwarded from that node. A message is delivered to its destination after being forwarded in this way by a series of nodes. Internet routing, however, not only provides routes, but also provides them in a way that adapts to the state of the network (Parker, 1994). The aim of this adaptive routing is to provide all the users of the network with the best possible common level of service regardless of the pattern of traffic carried by the network. The adaptation is controlled by network management centres that collect status information from network nodes, use this information to construct a representation of the state of the network and then send out messages to change the routing tables as necessary.

This way of achieving adaptive routing can be interpreted as a memetic system. The messages carrying the changes to the routing tables can be seen as memes, since they are, in essence, information patterns. The patterns can be interpreted by nodes in such a way as to bring about the required changes to the routing tables and so to the behaviour of the network. They spread across the network by being transmitted, and can be replicated as necessary, for example, if the same changes are needed at different nodes. A network management centre causes the memes to be modified in accordance with its representation of the state of the network. The aim of the modification is to cause the overall network to remain fit for its purpose despite its changing environment. The system can be redescribed in terms of a society. Nodes can be seen as the members of a 'network society'. Their capability is rather limited in that, as far as routing is concerned, they merely forward the messages that come to them. All the same, they co-operate with each other in an altruistic way to support routes across the network. In fact, a node will have no sense of the overall route of a message, merely passing it on to the next hop of its journey. Further, it will have no knowledge of messages in other parts of the network, and yet the other messages will be delivered to the same performance specification as the ones it handles. The purpose of the memes is to ensure that the routing tables are maintained in such a way that the 'network society' meets its goal no matter how the state of the network changes. The claim that

this is a memetic system must be accompanied by the rider that it is rather a limited one. The memes do not mutate or recombine, but are modified by a central controller in response to its perception of what is necessary. In the terminology used by Wilkins (1998), the memes are instructed.

3. Memetics at the service level

Agent technology is becoming ever more widely used on the Internet as a means of supporting services, notably search engines and 'push' services.

An agent can be defined as a message that can be sent into the network to perform some task and to return with the result. So, to give an example, Jango (to be found at <http://www.jango.com/>) is the name of an agent that can search on-line Internet stores for product availability and price information. Clearly, this agent must be able to locate sites of on-line stores, determine the products available at each site, and find their prices. In other words, it must have access to a program that tells it how to perform the task required of it. As an information pattern that can be replicated and spread across a network, an agent is a meme. Since it carries a program for performing a task, it provides a way of disseminating this program and, when there are different agents for the same task, they provide a basis for the selection of the best way of performing that task. Now consider the situation when several agents arrive at a node to carry out their various tasks. They could simply queue to carry out their tasks in succession so that eventually all the tasks would be done. It would, however, make better use of the scarce resource at their disposal if they co-operated with each other by, for example, sharing common tasks and ordering the tasks to facilitate the execution of the overall set of tasks. In this case, the set of agents can be seen as a meme complex and, when they co-operate, they will, if not exactly recombine, at least re-program one another. In terms of a society, the agents can be seen as the members, each having a single, possibly complex, capability, namely to perform the task required of them. The overall aim of the society is to perform the set of tasks contributed by its members.

The question that arises is: How should the agents co-operate? Memes for co-operation are needed! Co-operation can take place in many ways, including those that are benevolent or selfish, disruptive or co-operative, aggressive or submissive. Agents, as representatives of their dispatchers, should presumably co-operate in the same way as would their dispatchers. This makes it hard to envisage a uniform style of co-operation for agents, and an agent that is disposed to co-operate in a particular style must be able to react appropriately to an agent that attempts co-operation in a different fashion. Further, just as norms and laws govern co-operation in the real world, so, in the field of multi-agent systems, it is appreciated that social norms and laws are required for agent co-operation (Conte and Falcone, 1997). To summarise this, we can say that when services are implemented using agent technology, one agent can be seen as a meme, and a group of agents gathered in the same place as a meme complex. In this context, a meme is, again in the terminology used by Wilkins (1998), an interactor. The individual memes of a meme complex interact with each other, modifying themselves as required to achieve the overall aim of the group, which is to achieve their set of tasks in a way that is to the general benefit.

4. Memetics at the user level

The Internet, as mentioned earlier, supports the rapid and accurate world-wide transmission of the memes of its users. This is a supplement to, and not a replacement for, the traditional means of spreading memes. It is also, clearly, a means which makes use of a different medium. To the extent that the characteristics of the medium differ from those of the traditional medium, so the result of dispersing memes is, in turn, different.

It has been argued that the Internet's capability to spread memes across the world both accurately and instantaneously supports a tendency towards homogeneity in world culture (Heylighen, 1996). Memes can appear at much the same time in different parts of the world regardless of geographical and cultural boundaries to exert their effects. It has also been argued that the speed of transmission, and the resulting rapid cascade of memes across the Internet, makes it more difficult to distinguish between the more and less valuable memes (Taylor, 1996). There is a premium on short, catchy memes as opposed to more complex memes such as lengthy stories. Infectiousness assumes an importance far greater than that of attributes that may well have greater long-term value such as utility and authority.

With these insights, it is possible to sketch the essential differences between virtual and real-world communities. Virtual communities are not structured in the same way as real-world communities. Constraints of geography and status do not come into play: what matters is a common interest. But a diverse collection of people, perhaps drawn from all parts of the world and united by only a common interest, needs to construct its own culture. The network facilitates this with communication and the spread of memes. But, by comparison with the real world, memes are spread rapidly and accurately. This causes virtual communities to develop cultures that are narrow, often extreme and, in consequence, rather precarious (Marshall, 1998). Their precarious nature is re-inforced by the favouring of infectious memes over memes that might bring greater benefits in the long term, in that their adoption can result in a gap between the conceptions of the virtual world and those of the real world that is so great as to become unsustainable (Umpleby, 1996).

The increased use of agents brings another aspect to the situation in that they can be used to control the memes to which their dispatchers are exposed. Agents are a key element in the so-called 'push' technology with which users can specify the sort of information they want to receive, after which the network will 'push' that, and only that, information to them. As with any form of 'narrowcasting' this leads to the reinforcement of existing beliefs and the avoidance of the uncertainty associated with opposing, conflicting or even just different ideas (Salem and Gratz, 1997). This kind of selective attention produces individuals who are unaware of, or even afraid of, other views and of groups holding these views. In turn, this leads to social fragmentation and the production of incompatible social segments.

As a final point, the gulf between those with access to the network and those who do not is amplified by the fact that these groups exchange different memes in different ways. As Internet culture develops and moves farther from real-world culture, it becomes harder, not necessarily to gain access, but to join in effectively once access is gained. Besides this, there is the very real possibility of those with access to the network becoming cut off from their real-world history.

They may have no interest in it: those who do may not share the technical and cultural interests of those with access. The consequence can be a separation of those who spend most of their time on the network from their own history, which can only serve to widen further the gulf between those with access and those without.

5. Conclusions

This paper has shown that activities taking place at various levels in the organisation of the Internet can be interpreted in terms of memes and memetics. This provides a unified framework for examining the overall functioning and behaviour of the Internet. Given that the Internet is widely used for the communication of memes, this unified analysis has the real benefit of providing an account of the operation of the network that is coherent with the usage of the network. To the extent that the Internet is an archetypal network, these conclusions apply equally to any computer network.

The levels have been examined, starting from the bottom (hardware) level and working towards the top (user) level, to reveal their embedded memetic systems. The findings of the previous sections show that the simple memetic system supported at the operational level, in which the memes are instructed, is less complex than the system supported at the service level, where the memes are interactors. Again, the system at the service level is less complex than that at the user level which, with certain reservations, is a full-blown memetic system. Thus, the memetic system supported at a particular level is always less complex, and exerts greater control, than that supported by the level above. This finding is in tune with the rationale for adopting a layered approach to the design of a complex system, which is that the addition of a layer adds further capabilities to the overall system by building on those that already exist. In this way, the network supports the capability that users require by progressively building up this capability in a layered way with clear meta-system transitions. The memetic approach adopted here has made it possible to reveal this consistency of design and operation in a coherent way.

THOUGHTS AS TOOLS: THE MEME IN DANIEL DENNETT'S WORK

By
Kelby Mason

Most people interested in memes know of Daniel Dennett, at least by name; he seems to be the resident philosopher-mascot and is often mentioned in the context of memetics. It is therefore worthwhile to examine more closely his work in philosophy, to see how it relates to his memetics. Originally, I was going to discuss some of the objections to memetics raised by orthodox biologists, and how Dennett's ontology might deal with them. This proved to be beyond the scope of this paper, however, and instead I have chosen to focus specifically on the claim that memetics is reductionistic. I shall examine first Dennett's naturalism, then how this interacts with the alleged reductionism. Next I discuss the apparent threat of memetics to humanity's self-image, and finally some genuine problems posed by Dennett's treatment of memetics.

THREE NATURALIST SLOGANS

Daniel Dennett loves stories, metaphors and thought-experiments, and so it is suitably Dennettian to start this essay with a cartoon. In *Consciousness Explained* Dennett reproduces an illustration from *American Scientist*: two men stand before a complicated mathematical proof on a blackboard. At either end of the proof are the cartoonist's idea of arcane mathematical symbols, but in the middle the words "Then a Miracle Occurs". One of the two gentlemen suggests to the other, "I think you should be more explicit here in step two".

A little further on in the same book, the very first ground rule for Dennett's explanation of consciousness is "No Wonder Tissue allowed"; and a third slogan is provided in *Darwin's Dangerous Idea*: Skyhooks or Cranes? Skyhooks are miraculous forces postulated simply because of a failure to imagine how natural, material forces could produce the object of study. Cranes, on the other hand, are just such natural forces, and thus thoroughly respectable when used in explanation.

The three are equivalent: No Wonder Tissue Allowed, No Miracles, and No Skyhooks. In short, to co-opt a more familiar and less cute slogan, *Natura saltus non facit*; and therefore *nobis saltus facere non licet* in our explanations. Dennett's world-view is explicitly naturalistic; everything, including human consciousness, is to be explained in natural, not supernatural, terms. It may well turn out that science (or, if you prefer, Science) cannot explain everything. Until this is actually *shown* to be the case, however, Dennett will keep working away at his scientific edifice, forgoing miracles and skyhooks for slower yet more reliable cranes.

It is this "Standard Scientific Epistemology and Metaphysics" that Dennett believes to have led to his views on consciousness, intentionality and free will [2]. He supposes that he is simply working out the implications of "everyday science", what any materialist is led to believe. More importantly for present purposes, these implications include the *memetic* stance, as the best non-miraculous explanation of consciousness and culture.

It is also this "scientism" (better called naturalism) that has raised strong opposition to his whole enterprise. Dennett himself puts it well:

Those who see themselves as outside the gates of the scientific culture (which of course includes not just scientists, but all the science-literate, science-friendly people) see it as approximately as threatening to their own sense of power as Martians with advanced technology beyond our ken would seem to us. [9]

Or, as Bo Dahlbom says,

When peddled second-hand...Dennett comes off as something of a villain: a science-crazed mechanist, with a bleak and inhumane world-view, a rather superficial engineer compared to deep and serious thinkers like Thomas Nagel and John Searle" [2]

Indeed Dennett has concocted some disturbing descriptions of the memetic picture. The brain, he says, is "a sort of dung heap in which the larvae of other people's ideas renew themselves" [5]. Now of course the brain is not *really* a dung heap (at least *Dan's* isn't), but the image remains. If Dennett himself, memephile as he is, finds memetics at first "unsettling, even appalling" (*ibid.*), how will memephobes react?

Predictably enough, not well. Consider, for instance, the following from Richard Braddock: The meme theory is yet another attack on human subjectivity. Our complex social development is first simplified into technological progress, then reduced to culture, and finally explained away through the biology of memes. Our creativity and imagination as humans is once again denied. [1]

We can take Braddock as spokesman of a type of opponent not just to memes, but to any materialist account of humanity. Dennett, following Owen Flanagan, calls them "the New Mysterians" [5] because they are effectively arguing that some of the universe (specifically, the bit called "us") will *always* be inexplicable by science. The aforementioned Searle and Nagel are themselves leading advocates of this anti-materialism; and both are long-time foes of Dennett.

As shown by Braddock, the new mysterians generally have two concerns about memetics. The first is epistemological: memetics "explains away" culture and consciousness, and thus is not really an adequate theory. The second is moral/aesthetic: even if memetics were right, it would have such terrible consequences for our sense of creativity and freedom that we are better off leaving that Pandora's Box closed. Both concerns can be evaluated by with reference to Dennett's work.

WHAT'S WRONG WITH REDUCTIONISM, ANYWAY?

Every field has its own peculiar four-letter words that are substituted for genuine argument; once applied to an opponent, they leave no apparent need for further dispute. The list of dirty words in biology includes Lamarckism, vitalism, essentialism and, increasingly, reductionism. Dawkins remarks [4] that "a kind of "holistier than thou" self-righteousness has become fashionable" in

evolutionary theory. Dawkins should know, having been called a reductionist more often than anyone except perhaps Skinner, and Dennett himself.

In *Darwin's Dangerous Idea*, Dennett introduces a distinction between "good" and "greedy" reductionism. Good reductionism is basically materialism, a belief that material causes are necessary and sufficient for any phenomena. This sort of ontological reductionism does not, however, entail a commitment to theory reduction, the view that we should replace biology by physics. The difference between the two is well documented in philosophy of science.

Greedy reductionism, on the other hand, is when explaining is replaced by explaining away, "when overzealousness leads to falsification of the phenomena" and a denial of "the existence of real levels, real complexities, real phenomena" [7]. The explanatory paradigm is *too* simple and, accordingly, the data have to be squeezed and mangled beyond recognition to fit. This is the marrow of Dennett's earlier criticism of Skinner [6], that he mistakes good reductionism for greedy, and reductionism *qua* materialism for theory reduction.

In a sense, the real sin of greedy reductionism is against what Dahlbom calls "Dennett's very modern, very American, belief in hard work" [2]. The greedy reductionist is just lazy, glossing over complications and inconsistencies for the sake of her one simple, better yet simplistic, idea. With these important distinctions in mind, then, we can now ask what is meant by calling memetics reductionistic.

It is fairly clear what is meant by those other biological insults, all of them conjuring up the bad old pre-Darwinian days. Reductionism cannot, however, be such an insult, for while neo-Darwinism is definitely opposed to Lamarckism, vitalism and essentialism, it is by no means so obviously opposed to "reductionism". Neo-Darwinism itself could easily be labelled reductionist, insofar as it "explains away" complex adaptations by "mere" changes of gene frequencies in populations; and Dennett calls "Darwin's dangerous idea reductionism incarnate".

It cannot be therefore that when memetics is called "reductionist", what is meant is simply that it is materialist. We are all, I hope, materialists here, and if anyone wants to argue that we are begging the question by supposing that *some* materialist explanation of culture and mind is possible, then I agree. *Nolo contendere*: just as Dennett begs the question by calling good reductionism *good*, let us beg the question of materialism.

What is interesting is not the extreme claim that materialism itself can never explain mind/culture but the milder claim that *memetics* is not an adequate materialist explanation, that it is *greedy* reductionism. This is at the heart of Braddock's criticism, for he sees memetics as explaining away culture as the result of biology. If this were the case, then we should expect memetic papers such as "The Reproductive Advantages of Sonnet XVIII".

Yet memetics is not that sort of "biological reductionism", and must not be confused with socio-biology in the style of Edward O. Wilson. Rather, it seeks to explain human behaviour largely as the product of a new evolutionary domain which is not biological, although it builds on the biological. Precisely because it involves memes, it does not explain everything as due to biological foundations. Behaviour is explained by its relation, not as in socio-biology to genetic

reproduction, but to memetic reproduction; a crucial message of memetics is that the interests of these new replicators do not always coincide with those of the old.

It is not necessary, however, to confound memetics with socio-biology, to claim that it is greedy reductionism. One still might maintain that the mechanism of natural selection of memes is not powerful enough to explain mind/culture. How *could* memes possibly explain all the diversity of culture, as well as the subjectivity of consciousness?

Dennett sees this sort of argument as simply intellectually bankrupt. It is something he has long fought in philosophy; he calls it "Philosopher's Syndrome: mistaking a failure of imagination into an insight into necessity" [5]. To those who cannot understand how complexity can emerge from a simple process, Dennett replies: "Try harder". His work in philosophy of mind is largely devoted to showing that we can imagine such things, if only we try hard enough. Similarly, in much of *Darwin's Dangerous Idea*, Dennett tries to show that evolution by natural selection can explain natural history, without appealing for divine design.

Dennett likes to compare the mind to a computer, even calling it a "serial virtual machine implemented on the parallel hardware of the brain" [5]. Such comparisons are widespread in cognitive science, and John Searle parodies them by reminding us that similar comparisons were made to hydraulic systems and telephone switchboards when those technologies were new and fashionable [12]. Yet Searle has missed an important point: in all cases, the comparisons have not arisen because the Artificial Intelligentsia see everyone around them as zombie-like robots. Rather, it is precisely because they appreciate just how complex and impressive that technology can be, while having a thoroughly material basis.

Similarly, Dennett does not describe the mind as a meme complex because of a dehumanised view of humanity, but because he recognises the potential of the memetic stance to explain seemingly non-adaptive human behaviour. More importantly, he has learnt from Darwin that simple algorithms can create complex results, or in his own terms, that enough Cranes can simulate a Skyhook. Anyone suggesting that *au contraire* a memetic approach "reduces" or "explains away" mind/culture obviously has both an impoverished sense for the richness of biology and evolutionary theory, and a poor imagination.

IS MEMETICS AN ANTI-HUMANISM?

All this should suffice to show that memetics is not *a priori* greedy reductionism. Whether or not a workable science of memetics is possible is something only to be determined by the efforts of pioneer memeticists. This still leaves unresolved the other concern for the mysterians, that we should be worse off if memetics were successful. They argue that the more our "manifest image" of ourselves, as experiencing and effective agents, is affected by scientific investigation, the more our "creativity and imagination" is denied.

Now this sort of concern was widely voiced against Dawkins' *Selfish Gene*, and prompted a detailed response in Chapter 2 of *The Extended Phenotype*. There Dawkins criticises the "belief that genes are somehow super-deterministic". Even without considering this response, we can see that both Dawkins and Dennett identify with their memes, not their genes. Dawkins says

"We are built as gene machines and cultured as meme machines, but we have the power to turn against our creators. We, alone on earth, can rebel against the tyranny of the selfish replicators." [3]

and Dennett

there is, in the basement, a persisting tension between the biological imperative of the genes and the imperatives of the genes, but we would be foolish to side with' our genes [5]

If we are more closely related to our memes than our genes, then, we might ask with Dennett "Have we broken the tyranny of the selfish genes, only to be taken over by the selfish memes?" [7]

The problem with this question is that it misplaces our selves, where the "we" apparently controlled by our memes is supposed to be. For according to Dennett, "our *selves* have been created out of the interplay of memes" and it cannot be "memes versus us," because earlier infestations of memes have already played a major role in determining who or what we are. The "independent" mind struggling to protect itself from alien and dangerous memes is a myth. Finally, "what makes a person the person he or she is are the coalitions of memes that govern--- that play the long-term roles in determining which decisions are made along the way". [7]

Thus to think that in memetics we hand over our self-control to our memes instead, who then act as the Sinister Puppet Master, is to create an independent self that never has existed. It is as if we were to say "Who is responsible for what I do, is it myself? How, then, can *I* also be responsible for my actions, when myself is?" We *are* our memes, and the memes are running the show; therefore, so are we.

Moreover, the memetic stance is just another aspect of Dennett's broader strategy. In *Elbow Room* Dennett describes how as a student he had intended to be a sculptor and that he has "never abandoned the methods [he] developed in the studio, but simply changed media". He is making a different point, but this is also exactly how he sees ideas, as something to work at and something to work *with*. Ideas are tools and material for those tools. In fact, that whole book deals with the question of free will by studying our intuitions and how they mislead us, or rather how philosophers mislead us and each other by their "intuition pumps".

Dennett is in a general sense pursuing the Wittgensteinian project, revealing how we are trapped by "word games": the title of one chapter in *Consciousness Explained* is "How Words Do Things With Us". Dennett is trying to gain an understanding of ourselves, and to dissolve constructed mysteries. His is also similar to the Freudian project: "our therapeutic aim...[is] to restore the ego...to give it back the command over the id which it has lost" [11].

Far from crippling us with a sense of our own impotence, then, memetics should empower us. For it is not just as a science of thought that Dennett is interested in it, but also as a *technology* of thought. This conception of thoughts is one that encourages us to take control of them, and use them to their full advantage: if we can now get a science (in the form of memetics) of the ideas

that rule us then, according to Dennett, we will have that much more power over ourselves and our environment.

TWO DEBATABLE ISMS

Before concluding, I should like to say a few words on the possible limitations of Dennett's work, or at least indicate the underlying biases that colour his discussion of memes. For in spite of his claims, mentioned above, to be just a believer in traditional science, Dennett holds some unorthodox views on evolution. There is, for instance, what he himself admits to be a "shocking view", that we must apply the intentional stance to evolution in order to understand it; in other words, we need a personified Mother Nature.

Those of us particularly who are not biologists, and thus learn their evolutionary theory second-hand, should be careful not to take Dennett's orthodox credentials at face value. My questioning the two following aspects of Dennett's approach to memetics should not be interpreted as disagreement, but merely as a note of caution. Dennett does not *necessarily* have the right framework, and we need not only to decide for ourselves, but also to realise that there is a decision to be made in the first place.

I. Adaptationism This is neither the time nor place for a dissertation on the pros and cons of adaptationism. It suffices to point out that the debate over it is still a live one. Dennett's book is called Darwin's Dangerous Idea, not evolution's dangerous idea. He has correctly identified the central tenet of Darwinism as natural selection; but we must recognise that natural selection is not all there is to evolution. There may be other important mechanisms of memetic evolution, memetic drift, epimemetic constraints; or perhaps all memetic explanations will be just-so stories. Acknowledging the possibility of the former, however, does not mean abandoning materialism; the recognition of *other* Cranes does not equate to holding out for Skyhooks.

II. Atomism Similarly, gene selectionism is by no means universally accepted in biology. We need not therefore expect that the only fruitful research strategy in memetics will be an equally atomistic one that focuses on individual units of memes. Organism-centred selection worked for a long time in evolutionary biology; by analogy, a memetics centred on meme-complexes rather than single memes might be equally successful, not to mention easier to manage.

There is much that the memeticist can better understand from a familiarity with Dennett's work. In the first place, the firm situation of memetics within the naturalist tradition. Secondly, exactly how memetics is "reductionistic", what this entails, and what it does not. Memetics need not "explain away" anything, or threaten our moral ideas of self-control. While there may also be dangers in reading Dennett as gospel, these are not insuperable and may be overcome. Dahlbom calls Dennett an optimist [2] and ultimately his memetics too is optimistic. Via the technology of memetics, we should be even more able to take control of our selves, the encouragement of which has been Dennett's project all along.

THE FUTURE OF MAN

By
Sir Peter Medawar
(1995)

In this last lecture, I shall discuss the origin in human beings of a new, a non-genetical, system of heredity and evolution based upon certain properties and activities of the brain. The existence of this non-genetical system of heredity is something you are perfectly well aware of. It was not biologists who first revealed to an incredulous world that human beings have brains; that having brains makes a lot of difference; and that a man may influence posterity by other than genetic means. Yet much of what I have read in the writings of biologists seems to say no more than this. I feel a biologist should contribute something towards our *understanding* of the distant origins of human tradition and behavior, and this is what I shall now attempt. The attempt must be based upon hard thinking, as opposed to soft thinking; I mean, it must be thinking that covers ground and is based upon particulars, as opposed to that which finds its outlet in the mopings or exaltation of poetistic prose.

It will make my argument clearer if I build it upon an analogy. I should like you to consider an important difference between a juke-box and a gramophone --- or, if you like, between a barrel-organ and a tape-recorder. A juke-box is an instrument which contains one or more gramophone records, one of which will play whatever is recorded upon it if a particular button is pressed. The act of pressing the button I shall describe as the "stimulus." The stimulus is specific: to each button there corresponds one record, and vice versa, so that there is a one-to-one relationship between stimulus and response. By pressing a button --- any button --- I am, in a sense, instructing the juke-box to play music; by pressing this button and not that, I am instructing it to play one piece of music and not another. But --- I am not giving the juke-box *musical* instructions. The musical instructions are inscribed upon records that are part of the juke-box, not parts of its environment: what a juke-box or barrel-organ can play on any one occasion depends upon structural or inbuilt properties of its own. I shall follow Professor Joshua Lederberg in using the word "elective" to describe the relationship between what the juke-box plays and the stimulus that impinges upon it from the outside world.

Now contrast this with a gramophone or any other reproducing apparatus. I have a gramophone and one or more records somewhere in the environment outside it. To hear a particular piece of music, I go through certain motions with switches, and put a gramophone record on. As with the juke-box I am, in a sense, instructing the gramophone to play music, and a particular piece of music. But I am doing more than that: I am giving it musical instructions, inscribed in the grooves of the record I make it play. The gramophone itself contains no source of musical information. My relationship to the gramophone --- again following Lederberg --- I shall describe as "instructive"; for, in a sense, I *taught* it what to play. With the juke-box, then --- and the same goes for a musical-box or barrel-organ --- the musical instructions are part of the system that responds to stimuli, and the stimuli are elective: they draw upon the inbuilt capabilities of the instrument. With a gramophone, and still more obviously with a tape recorder, the stimuli are instructive: they endow it with musical capabilities; they import into it musical information from the world outside.

It is we ourselves who have made juke-boxes and gramophones, and who decide what, if anything, they are to play. These facts are irrelevant to the analogy I have in mind, and can be forgotten from now on. Consider only that organism on the one hand --- juke-box or gramophone; and on the other hand, stimuli which impinge upon that organism from the world about it.

During the past ten years, biologists have come to realize that, by and large, organisms are very much more like juke-boxes than gramophones. Most of those reactions of organisms which we were formerly content to regard as instructive are in fact elective. The instructions an organism contains are not musical instructions inscribed in the grooves of a gramophone record, but **genetical** instructions embodied in chromosomes and nucleic acids. Let me give examples of what I mean.

The oldest example, and the most familiar, concerns the change that comes over a population of organisms when it undergoes an evolution. How should we classify the environmental stimuli that cause organisms to evolve? The Lamarckian theory, the theory that acquired characters can be inherited, is, in its most general form, an **instructive** theory of evolution. It declares that the environment can somehow issue genetical instructions to living organisms --- instructions which, duly assimilated, can be passed on from one generation to the next. The blacksmith who is usually called upon to testify on these occasions gets mightily strong arms from forging; somehow this affects the cells that manufacture his spermatozoa, so that his children start life especially well able to develop strong arms. I have no time to explain our tremendous psychological inducement to believe in an instructive or Lamarckian theory of evolution, though in a somewhat more sophisticated form than this. I shall only say that every analysis of what has appeared to be a Lamarckian style of heredity has shown it to be **non-Lamarckian**. So far as we know, the relationship between organism and environment in the evolutionary process is an elective relationship. The environment does **not** imprint genetical instructions upon living things.

Another example: bacteriologists have known for years that if bacteria are forced to live upon some new unfamiliar kind of foodstuff or are exposed to the actions of an anti-bacterial drug, they acquire the ability to make use of that new food, or to make the drug harmless to them by breaking it down. The treatment was at one time referred to as the **training** of bacteria --- with the clear implication that the new food or drug **taught** the bacteria how to manufacture the new ferments upon which their new behavior depends. But it turns out that the process of training belies its name: it is not instructive. A bacterium can synthesize only those ferments it is genetically entitled to synthesize. The process of training merely brings out or exploits or develops an innate potentiality of the bacterial population, a potentiality underwritten or subsidized by the particular genetic make-up of one or another of its members.

The same argument probably applies to what goes on when animals develop. At one time there was great argument between "preformationists" and those who believed in epigenesis. The preformationists declared that all development was an unfolding of something already there; the older extremists, whom we now laugh at, believed that a sperm was simply a miniature man. The doctrine of epigenesis, in an equally extreme form, declared that all organisms begin in a homogeneous state, with no apparent or actual structure; and that the embryo is moulded into its adult form solely by stimuli impinging upon it from outside. The truth lies somewhere between

these two extreme conceptions. The genetic instructions are preformed, in the sense that they are already there, but their fulfilment is epigenetic ---- an interpretation that comes close to an elective theory of embryonic development. The environment brings out potentialities present in the embryo in a way which (as with the buttons on a juke-box) is exact and discriminating and specific; but it does not *instruct* the developing embryo in the manufacture of its particular ferments or proteins or whatever else it is made of. Those instructions are already embodied in the embryo: the environment causes them to be carried out.

Until a year or two ago we all felt sure that *one* kind of behavior indulged in by higher organisms did indeed depend on the environment as a teacher on instructor. The entry or injection of a foreign substance into the tissues of an animal brings about an immunological reaction. The organism manufactures a specific protein, an "antibody," which reacts upon the foreign substance, often in such a way as to prevent its doing harm. The formation of antibodies has a great deal to do with resistance to infectious disease. The relationship between a foreign substance and the particular antibody it evokes is exquisitely discriminating and specific; one human being can manufacture hundreds --- conceivably thousands --- of distinguishable antibodies, even against substances which have only recently been invented, like some of the synthetic chemicals used in industry or in the home. Is the reaction instructive or elective? --- surely, we all felt, instructive. The organism learns from the chemical pattern of the invading substance just how a particular antibody should be assembled in an appropriate and distinctive way. Self-evident though this interpretation seems, many students of the matter are beginning to doubt it. They hold that the process of forming antibodies is probably elective in character. The information which directs the synthesis of particular antibodies is part of the inbuilt genetical information of the cells that make them; the invading foreign substance exploits that information and brings it out. It is the juke-box over again. I believe this theory is somewhere near the right one, though I do not accept some of the special constructions that have been put upon it.

So in spite of all will to believe otherwise, and for all that it seems to go against common sense, the picture we are forming of the organism is a juke-box picture --- a juke-box containing genetical instructions inscribed upon chromosomes and nucleic acids in much the same kind of way as musical instructions are inscribed upon gramophone records. But what a triumph it would be if an organism could accept information from the environment --- if the environment could be made to act in an instructive, not merely an elective, way! A few hundred million years ago a knowing visitor from another universe might have said: "It's a splendid idea, and I see the point of it perfectly: it would solve --- or could solve --- the problems of adaptation, and make it possible for organism to evolve in a much more efficient way than by natural selection. But it's far too difficult: it simply can't be done."

But you know that it has been done, and that there is just one organ which can accept instruction from the environment: the brain. We know very little about it, but that in itself is evidence of how immensely complicated it is. The evolution of a brain was a feat of fantastic difficulty --- the most spectacular enterprise since the origin of life itself. Yet the brain began, I suppose, as a device for responding to elective stimuli. *Instinctive* behavior is behavior in which the environment acts electively. If male sex hormones are deliberately injected into a hen, the hen will start behaving in male-like ways. The potentiality for behaving in a male-like manner must therefore have been present in the female; and by pressing (or, as students of behavior usually

say, "releasing") the right button the environment can bring it out. But the higher parts of the brain respond to instructive stimuli: we *learn*.

Now let me carry the argument forward. It was a splendid idea to evolve into the possession of an organ that can respond to instructive stimuli, but the idea does not go far enough. If that were the whole story, we human beings might indeed live more successfully than other animals; but when we died, a new generation would have to start again from scratch. Let us go back for a moment to genetical instructions. A child at conception receives certain genetical instructions from its parents about how its growth and development are to proceed. Among these instructions there must be some which provide for the issue of further instructions; I mean, a child grows up in such a way that it, too, can eventually have children, and convey genetical instructions to them in turn. We are dealing here with a very special system of communication: a *hereditary* system. There are many examples of systems of this kind. A chain letter is perhaps the simplest: we receive a letter from a correspondent who asks us to write to a third party, asking him in turn to write a letter of the same kind to a fourth, and so on --- a hereditary system. The most complicated example is provided by the human brain itself; for it does indeed act as intermediary in a hereditary system of its own. We do more than learn: we teach and hand on; tradition accumulates; we record information and wisdom in books.

Just as a hereditary system is a special kind of system of communication --- one in which the instructions provide for the issue of further instructions --- so there is a specially important kind of hereditary system: one in which the instructions passed on from one individual to another change in some systematic way in the course of time. A hereditary system with this property may be said to be conducting or undergoing an *evolution*. Genetic systems of heredity often transact evolutionary changes; so also does the hereditary system that is mediated through the brain. I think it is most important to distinguish between four stages in the evolution of a brain. The nervous system began, perhaps, as an organ which responded only to elective stimuli from the environment; the animal that possessed it reacted instinctively or by rote, if at all. There then arose a brain which could begin to accept instructive stimuli from the outside world; the brain in this sense has dim and hesitant beginnings going far back in geological time. The third stage, entirely distinguishable, was the evolution of a non-genetical system of heredity, founded upon the fact that the most complicated brains can do more than merely receive instructions; in one way or another they make it possible for the instructions to be handed on. The existence of this system of heredity --- of tradition, in its most general sense --- is a defining characteristic of human beings, and it has been important for, perhaps, 500,000 years. In the fourth stage, not clearly distinguishable from the third, there came about a systematic change in the nature of the instructions passed on from generation to generation --- an evolution, therefore, and one which has been going on at a great pace in the past 200 years. I shall borrow two words used for a slightly different purpose by the great demographer Alfred Lotka to distinguish between the two systems of heredity enjoyed by man: *endosomatic* or internal heredity for the ordinary or genetical heredity we have in common with animals; and *exosomatic* or external heredity for the non-genetic heredity that is peculiarly our own --- the heredity that is mediated through tradition, by which I mean the transfer of information through non-genetic channels from one generation to the next.

I am, of course, saying something utterly obvious: society changes; we pass on knowledge and skills and understanding from one person to another and from one generation to the next; a man can indeed influence posterity by other than genetic means. But I wanted to put the matter in a way which shows that we must not distinguish a strictly biological evolution from a social, cultural or technological evolution: *both* are biological evolutions: the distinction between them is that the one is genetical and the other is not.

What, then, is to be inferred from all this? What lessons are to be learned from the similarities and correspondences between the two systems of biological heredity possessed by human beings? The answer is important, and I shall now try to justify it: the answer, I believe, is almost none.

It is true that a number of amusing (but in one respect highly dangerous) parallels can be drawn between our two forms of heredity and evolution. Just as biologists speak in a kind of shorthand about the "evolution" of hearts or ears or legs --- it is too clumsy and long-winded to say every time that these organs participate in evolution, or are outward expressions of the course of evolution --- so we can speak of the evolution of bicycles or wireless sets or aircraft with the same qualification in mind: they do not really evolve, but they are appendages, exosomatic organs if you like, that evolve with us. And there are many correspondences between the two kinds of evolution. Both are gradual if we take the long view; but on closer inspection we shall find that novelties arise, not everywhere simultaneously -- pneumatic tires did not suddenly appear in the whole population of bicycles -- but in a few members of the population: and if these novelties confer economic fitness, or fitness in some more ordinary and obvious sense, then the objects that possess them will spread through the population as a whole and become the prevailing types. In both styles of evolution we can witness an adaptive radiation, a deployment into different environments: there are wireless sets not only for the home, but for us in motor-cars or for carrying about. Some great dynasties die out ---airships, for instance, in common with the dinosaurs they were so often likened to; others become fixed and stable: toothbrushes retained the same design and construction for more than a hundred years. And, no matter what the cause of it, we can see in our exosomatic appendages something equivalent to vestigial organs: how else should we describe those functionless buttons on the cuffs of men's coats?

All this sounds harmless enough: why should I have called it dangerous? The danger is that by calling attention to the similarities, which are not profound, we may forget the *differences* between our two styles of heredity and evolution; and the differences between them are indeed profound. In their hunger for synthesis and systematization, the evolutionary philosophers of the nineteenth century and some of their modern counterparts have missed the point: they thought that great lessons were to be learnt from the similarities between Darwinian and social evolution; but it is from the differences that all the great lessons are to be learnt. For one thing, our newer style of evolution is Lamarckian in nature. The environment cannot imprint genetical information upon us, but it can and does imprint non-genetical information which we can and do pass on. Acquired characters are indeed inherited. The blacksmith was under an illusion if he supposed that his habits of life could impress themselves upon the genetic make-up of his children; but there is no doubting his ability to teach his children his trade, so that they can grow up to be as stalwart and skillful as himself. It is because this newer evolution is so obviously Lamarckian in character that we are under psychological pressure to believe that genetical

evolution must be so too. But although one or two biologists are still feebly trying to graft a Lamarckian or instructive interpretation upon ordinary genetical evolution, they are not nearly so foolish or dangerous as those who have attempted to graft a Darwinian or purely elective interpretation upon the newer, non-genetical, evolution of mankind.

The conception I have just outlined is, I think, a liberating conception. It means that we can jettison all reasoning based upon the idea that changes in society happen in the style and under the pressures of ordinary genetic evolution; abandon any idea that the direction of social change is governed by laws other than laws which have at some time been subject of human decisions or acts of mind. That competition between one man and another is a necessary part of the texture of society; that societies are organisms which grow and must inevitably die; that division of labor within a society is akin to what we can see in colonies of insects; that the laws of genetics have an overriding authority; that social devolution has a direction forcibly imposed upon it by agencies beyond man's control --- all these are biological judgments; but, I do assure you, bad judgments based upon a bad biology. In these lectures you will have noticed that I advocate a ``humane" solution to the problems of eugenics, particularly of the problems of those who have been handicapped by one or another manifestation of the ineptitude of nature. I have not claimed, and do not now claim, that humaneness is an attitude of mind enforced or authorized by some deep inner law of exosomatic heredity: there are technical reasons for supposing that no such laws can exist. I am not warning you against quack biology in order to set myself up as a rival peddler of patent medicines. What I do say is that our policies and intentions are not to be based upon the supposition that Nature knows best; that we are at the mercy of natural laws, and flout them at our peril.

It is a profound truth --- realized in the nineteenth century by only a handful of astute biologists and by philosophers hardly at all (indeed, most of those who held and views on the matter held a contrary opinion) --- a profound truth that Nature does *not* know best; that genetical evolution, if we choose to look at it liverishly instead of with fatuous good humor, is a story of waste, makeshift, compromise and blunder.

I could give a dozen illustrations of this judgment, but shall content myself with one. You will remember my referring to the immunological defenses of the body, the reactions that are set in train by the invasion of the tissues by foreign substances. Reactions of this kind are more than important: they are essential. We can be sure of this because some unfortunate children almost completely lack the biochemical aptitude for making antibodies, the defensive substances upon which so much of resistance to infectious disease depends. Until a few years ago these children died, because only antibiotics like penicillin can keep them alive; for that reason, and because the chemical methods of identifying it have only recently been discovered, the disease I am referring to was only recognized in 1952. The existence of this disease confirms us in our belief that the immunological defenses are vitally important; but this does not mean that they are wonders of adaptation, as they are so often supposed to be. Our immunological defenses are also an important source of injury, even of mortal injury.

For example: vertebrate animals evolved into the possession of immunological defenses long before the coming of the mammals. Mammals are viviparous: the young are nourished for some time within the body of the mother: and this (in some ways) admirable device raised for the first

time in evolution the possibility that a mother might react immunologically upon her unborn children --- might treat them as foreign bodies or as foreign grafts. The haemolytic disease that occurs in about one new-born child in 150 is an error of judgment of just this kind: it is, in effect, an immunological repudiation by the mother of her unborn child. Thus the existence of immunological reactions has not been fully reconciled with viviparity; and this is a blunder --- the kind of blunder which, in human affairs, calls for a question in the House, or even a strongly worded letter to *The Times*.

But this is only a fraction of the tale of woe. Anaphylactic shock, allergy, and hypersensitivity are all aberrations or miscarriages of the immunological process. Some infectious diseases are dangerous to us not because the body fails to defend itself against them but --- paradoxically --- because it does defend itself: in a sense, the remedy *is* the disease. And within the past few years a new class of diseases has been identified, diseases which have it in common that the body can sometimes react upon its own constituents as if they were foreign to itself. Some diseases of the thyroid gland and some inflammatory diseases of nervous tissue belong to this category; rheumatoid arthritis, lupus erythematosus, and sclerodma may conceivably do so too. [They do. PM] I say nothing about the accidents that used to occur in blood transfusions, immunological accidents; nor about the barriers, immunological barriers, that prevent our grafting skin from one person to another, useful though it would so often be; for transfusion and grafting are artificial processes, and, as I said in an earlier lecture, natural evolution cannot be reproached for failing to foresee what human beings might get up to. All I am concerned to show is that natural devices and dispositions are highly fallible. The immunological defenses are dedicated to the proposition that anything foreign must be harmful; and this formula is ground out in a totally indiscriminating fashion with results that are sometimes irritating, sometimes harmful, and sometimes mortally harmful. It is far better to have immunological defenses than not to have them; but this does not mean that we are to marvel at them as evidences of a high and wise design.

We can, then, improve upon nature but the possibility of our doing so depends, very obviously, upon our continuing to explore into nature and to enlarge our knowledge and understanding of what is going on. If I were to argue the scientists' case, that case that exploration is a wise and sensible thing to do, I should try to convince you of it by particular reasoning and particular examples, each one of which could be discussed and weighed up; some, perhaps, to be found faulty. I should not say: Man is driven onwards by an exploratory instinct, and can only fulfil himself and his destiny by a ceaseless quest for Truth. As a matter of fact, animals do have what might be loosely called an inquisitiveness, an exploratory instinct; but even if it were highly developed and extremely powerful, it would still not be binding upon us. We should not be *driven* to explore.

Contrariwise, if someone were to plead the virtues of an intellectually pastoral existence, not merely quite but acquiescent, and with no more than a pensive regret for not understanding what could have been understood; then I believe I could listen to his arguments and, if they were good ones, might even be convinced. But if he were to say that this course of action or inaction was the life that was authorized by Nature; that this was the life Nature provided for and intended us to lead; then I should tell him that he had no proper conception of Nature. People who brandish naturalistic principles at us are usually up to mischief. Think only of what we have suffered from

a belief in the existence and overriding authority of a fighting instinct; from the doctrines of racial superiority and the metaphysics of blood and soil; from the belief that warfare between men or classes of man or nations represents a fulfilment of historical laws. These are all excuses of one kind or another, and pretty thin excuses. The inference we can draw from an analytical study of the differences between ourselves and other animals is surely this: that the bells which toll for mankind are ---- most of them, anyway --- like the bells on Alpine cattle; they are attached to our own necks, and it must be *our* fault if they do not make a cheerful and harmonious sound.

EVOLUTIONARY PARADIGM FOR GLOBAL POLITICS
INTERNATIONAL STUDIES QUARTERLY
Vol. 40(3), September 1996, pp.321-342

By
George Modelski
Department of Political Science
University of Washington

Abstract: The evolutionary paradigm for global politics here presented consists of four key propositions: (1) The global political system is a population of policies or strategies; (2) Global politics constitutes a complex system that evolves in specifiable conditions; (3) Accounting for global political evolution is a four-phased learning process whose key operators are variation (innovation), cooperation, selection, and reinforcement; (4) Global politics coevolves with global economics, community, and opinion etc. The evolutionary paradigm sheds light on two processes in particular: the formation of institutions at the global level, and the rise and decline of world powers (the long cycle).

Two propositions are central to this paper: (1) the institutions of world politics evolve, that is they undergo change subject to identifiable evolutionary processes, and (2) the rise and decline of world powers (the long cycle) is a mechanism of global political evolution.

By institutions of world politics we mean constitutive and widely accepted arrangements in respect of war and peace, nation-states, alliances, and international organization, and global leadership and international law. If we consider these arrangements in a sufficiently long perspective, say over the span of the past millennium, we cannot but help noticing significant changes that have occurred in relation to these, that continue to affect them, and that therefore need to be understood and explained. We need a structural-historical theory of world politics. The rise and decline of world powers, that has been the lead story of the past few centuries of world politics, also needs to be understood in a wider framework. It is not the case of some eternal struggle for power but rather that of a mechanism that in the recent past has mediated major changes in world political and social organization. We need to see the long cycle not in isolation but as a feature of world institutional growth.

That is why, to better understand world politics in its time dimension in particular, we require an evolutionary framework. What might be the salient features of such a paradigm?

EVOLUTIONARY PARADIGMS

Types of evolution

What is a paradigm? A paradigm is an exemplary pattern that identifies the key questions and the fundamental variables; more generally it is a set of canons for the statement of problems of general significance that is espoused, or shared, by a research community.

What does the pattern exemplify? It represents a conception of the natural order of things, and specifies what, in a particular realm, is to be normally expected. Explanations then amount to showing why actual events diverge from 'normal', that is 'reasonable', expectations. A paradigm defines, for a class of events, what stands to reason.

An evolutionary paradigm is one such pattern. Kenneth Boulding (1981:9, 25), a social scientist, described it as "a pattern of the universe", "a pattern in space-time". Like Herbert Spencer before him /1/, Boulding saw this pattern characterizing not only the biological world, but also the physical universe, viewed on the very large scale of cosmology, and also the social world. If, following Spencer, culture is added to that list as a separate realm, also subject to these considerations, four types of evolution emerge: physical, biological, social, and cultural that can be ranked along a time axis according to the period of their evolutionary processes. Thus cosmology and geology operate on a time scale of billions of years; the story of life, and the animal kingdom on earth is reckoned over tens and hundreds of millions years. Social organization, for humans in particular, does not extend much over hundreds of thousand years, into some million, and culture has an even shorter time span. All of these major processes together make up evolution, but they all need to be kept distinct, too, if only because their periods vary.

That makes evolution a pervasive pattern of some considerable power and generality. It is indispensable in grasping long-range processes even though it is not claimed to be a pattern of everything and does not explain every class of event or process. But does that also mean that the study of evolution necessarily involves a hierarchy of sciences, and that biology, as the science of life, has an inherent or overriding claim on priority of insight in evolutionary theory? Not necessarily. In the evolution of evolutionary theory, all branches of knowledge (that are fields of culture) have participated in the past and continue doing so. In mid-nineteenth century, biologist Charles Darwin captured public attention with an account of the origin of the species, and his name came to be completely identified with the concept of evolution by natural selection. But his own insights and discoveries were profoundly shaped not only by earlier work in geology, such as that of Charles Lyell, whose principle of "uniformitarianism" (that past changes are to be accounted by processes still in operation) is basic to Darwin's work, but also by that formative work in early demography, Thomas Malthus' "Essay on the Principle of Population". What is more, sociologist Herbert Spencer developed his own concept of evolution even before Darwin's work had appeared in print.

That is why each type of evolution may also be regarded as occupying its own domain, and privileged time-space. The knowledge of each contributes to evolutionary theory, and researches mutually cross fertilize work on all others. While evolutionary conceptions have recently had particularly full elaboration in biological theory, no one should forget the role of geology and astronomy in pioneering the understanding of deep time. Claims to priority or one-way influence by any one field of evolutionary study need to be treated with caution.

Social science evolutionary paradigms

The present study is therefore located in social evolution, and in the social sciences, and concerns global politics as one sub-type of social evolutionary process. What are the essentials of

an evolutionary paradigm for the social sciences? /2 / According to R.C Lewontin writing in the International Encyclopedia of the Social Sciences (1968:203): "There is a hierarchy of principles in the evolutionary world view: *change, order, direction, progress, and perfectibility*. Evolutionary theories are distinguished by how many of these are successively included as essential."

These five principles serve as a convenient framework for discussion. The argument will be that, for present purposes, the essential ingredients of the evolutionary paradigm for the social sciences are only two: change, and direction. Order, progress, and perfectibility are not essential parts of such a framework.

Change

The most basic evolutionary considerations center around "change". An evolutionary perspective represents "a commitment to the instability of the present order as well as the past. In its simplest and irreducible form evolutionism is the doctrine that change of state is an unvarying characteristic of natural systems and human institutions and that such change follows immutable laws" (Lewontin, *ibid.*).

Change of state in societies means change in the economic, political, societal, and cultural structures that constitute them. Structural change is to be distinguished from routines that characterize all social life; (this distinction is central e.g. to the Nelson and Winter (1982) analysis of economic development). Structural change commonly represents innovation that is a departure from standard operating procedures, and that is why the story of social evolution is a record of innovation. But structural change, or the diffusion of innovation, also takes time, and that is why the observation of change in human institutions invariably requires a long perspective.

Such an approach is clearly structuralist, in that it proposes that the persisting clusters of social behavior that are subject to social evolution form emergent social structures whose properties cannot be deduced from the parts composing them, and that it focuses on transformations of these structures. It emphasizes change, rather than "evolutionary stages" that are often seen as the principal products of evolution analysis, and often reified, or even personified, as in "capitalism". It is not functionalist in that it does not inquire into the functions of persisting structures, but it does search for explanations of change in these structures.

Distinguishing "structural" from "routine" change helps to get over the problem that Lewontin raises, of separating "real" change from a stasis that has only the appearance of change. But to assert that evolution is structural change does not necessarily imply the statement that order is the natural outcome of evolutionary processes. A more modest proposition would stipulate that such processes are concerned with adaptation; that is, they might cope with a set of identifiable problems, in relation to which they may, or may not, be adaptive.

Directionality

Lewontin's third principle (1968:204), direction, also is a basic one. "By direction in evolution we mean the concept that there is some natural linear order of states of the system and that an evolutionary process can be described as passing through successive states in that order" in a line that is always ascending or descending.

Is the scale on which such directionality can be measured differentiation, or complexity, as Herbert Spencer first proposed it? Over very long periods, we can observe both differentiation, and increase in complexity in social systems. In the evolution of the world system of the past millennium, a prominent instance of differentiation has been the formation of the global and national systems, where previously there was only regional and local organization. Arguably, too, the world system was less complex ca. 1000 than it is going to be in the year 2000. But is such differentiation, and higher complexity due to evolution, and if so how?

Directionality does not posit the existence of a design, or blueprint; "genes are much more like a recipe than like a blueprint" (Dawkins 1987:296), and it is not teleological, in the sense of implying search for evidence of such design in nature. It does not lead to "laws of history" proclaiming developmental sequences familiar in, and rejected by, the social sciences such as that of "feudalism ---> capitalism" leading to the "final goal" of socialism".

But directionality does imply that evolution is not random and that it is a cumulative process, whereby a succession of small changes can bring about great transformations (Dawkins 1987:Ch.3). A recipe is a set of ingredients, and a set of instructions. Instructions organize the process in time thus giving it a temporal structure; evolution might be thought of as involving some such instructions. Ingredients compose the conditions that induce evolution; they define the spatial aspect of that process.

Directionality can be made more tractable at shorter time frames if it understood to be the product of learning. J.W. Pringle (1951) has shown that learning viewed as increased complexity of behavior over time, may be thought of as equivalent to organic evolution, usually thought of as increased structural complexity (in space); hence social evolution is basically about learning new behavior (see also Campbell 1969, Schull 1991). Successful social learning produces structural change; a learning process, furthermore, is inherently phased, has a distinct time-structure, hence direction. It might therefore be argued that it is learning that gives directionality to evolutionary processes. It could be seen as a "natural" process of trial and error, as if the unwinding of an internal logic or program of adaptation, one that does not require the postulation of a grand design or purposeful intention, but does call for an explanation.

Such an approach is neither deterministic, nor does it assume randomness; it is probabilistic. /3/ It favors directionality without projecting for it a fixed content or a finite purpose, and does not require the teleological assumption of a final goal or destination. It requires adjustment to changing conditions of the world system, including environment, population, urbanization, technology, and wealth, but does not require the assumption of a grand design. All it says is that the system under study proceeds on its way in a certain manner, and according to codes, or programs, that need to be explicated. It obeys a set of rules in that it plays out in a given natural

and social environment that includes other processes and policies each carrying out their own programs. All such a model does is to postulate an "inner logic", that is the formal-logical requirement that the processes evince a time-structure that constrains them.

Progress and perfectibility

There is a tradition of long standing (cf. review in Ginsberg 1961) that regards progress as an essential characteristic of evolution. Progress is not identical with evolution, but is linked to it: it is evolution in a direction that satisfies certain criteria of value. The prominent formulations of the idea of progress date from the era of the Enlightenment. The most famous among these formulations were those of Condorcet, and his criteria, that included equality, and peace, do not seem as utopian as they were once made out to be. But whether the study of social evolution can by itself provide the relevant criteria of value is a matter for debate. And even if the criteria were agreed, there is room for disagreement as to whether or to what degree the record of human history, be it of the 20th century, of the last millennium, or of the past 10,000 years, shows progress in the human condition. Some social evolutionists maintain that any such claim is misplaced and that no such progress has in fact occurred.

These are matters still open to discussion, both on empirical and on theoretical grounds. But they make it clear that it would be unwise to include progress, movement in a "good" direction, among the essential traits of social evolution. Biologists have had some difficulty specifying precisely what might be meant by biological progress. Suffice it to say that a "learning" conception of the directionality of evolution keeps open the possibility of progress, but leaves the determination of the precise characteristics of that progress to the analysis of cases. A "learning" conception of social evolution leaves room not only for "materialist" components (of wealth and power) but also for "idealist" elements (of truth, and love) that make for a well-rounded analysis. Lewontin's fifth principle, perfectibility, is even more stringent. This again, is a criterion of Condorcet (a mathematician), who saw it as a limit toward which the process might be moving, without ever attaining it. To-day evolution is more often viewed as an endless process with no ultimate goal or destination, and even a "learning" conception stresses in the first place adaptation to current problems rather than final purpose. But as Lewontin points out (1968:206) if there is directionality on some criterion, then perfectibility cannot be altogether ignored.

Indeed, for social evolution it raises the problem of a possible life cycle for the human species. Could it be programmed to die out at the end of such a cycle?

Macro- and micro-evolution

This discussion leaves us with two main evolutionary principles: structural change, and Formal-logical directionality. It remains to point out that these are broadly equivalent to the two major divisions of biological theory: macro- and microevolution. These are very basic distinctions, even if the dividing line between macro and micro, description and explanation is not as sharp as it might be thought to be.

Biological theorists (such as Ayala 1982, Pollard 1984) commonly now divide evolutionary (or the synthetic) theory into two areas, macroevolution and microevolution. Macroevo-

meaning the evolution of all living groups, considers the question whether evolution has occurred and by what pathways. It was called the theory of descent by Darwin (who defined evolution as descent with modification), and sometimes is called the fact of evolution, with a strong descriptive element. Darwin's "tree of life" is the most general graphic representation of the observed facts of evolutionary change.

Microevolution is the study of the mechanism of evolution. Darwin suggested that natural selection was a chief mechanism that explains the non-random aspects of evolution, and thus supplied a principal explanation for the observed variety of life forms, but we now think of it as one among such mechanisms. These mechanisms could be thought of as supplying the directionality of evolution.

The discussion of Lewontin's principles has now brought the subject down essentially to where biological theory also finds itself. But do we wish to draw, in our own analysis, a sharp distinction between micro- and macro-evolution, between fact and explanation? Probably not, because the boundaries between description and explanation are not really that sharp; good description and classification imply a good theory, and convincing explanations need to be tested against data collected on the basis of a theoretical scheme. What is more, macro-analysis requires reliable knowledge of micro-conditions, and vice versa.

How do such distinctions apply to the study of social evolution? Are conditions such that an "evolutionary analogy" is in fact justified?

Comte-Spencer v. Darwin

Since the second half of the 19th century, two conceptions of evolutionary theory have existed side by side: the Comte-Spencerian, and the Darwinian.

Auguste Comte, and after him, Herbert Spencer, proposed that human evolution passed through major stages of social development. Also referred to as "evolutionism", this view emphasized major stages that might be manifested in the history of humanity, and could therefore be regarded as a form of "macro-evolutionary" analysis.

The Darwinian model elucidated a central causal mechanism of evolution to explain continuity and change in populations, but avoided the temptation for quick explanations of socio-historical processes. It centered on the analysis of selection, and for that reason has also been referred to as selectionism. In the social sciences, Darwinian selectionism is a form of "micro-evolutionary" analysis.

Over time, the Comte-Spencerian program fell into disuse, even if the problems it was intended to tackle, understanding large-scale change in human affairs, has not disappeared. But in mid-20th century, Darwinian theory experienced a strong revival and reinvigoration through a "modern synthesis" (Huxley 1942, 3rd ed. 1974) that followed the revolution in genetics and was followed by the discovery of DNA, that in turn has been subject to much critical analysis (e.g. Pollard 1984), and that also exerted much influence on the social sciences.

Our project here is to combine these two conceptions. Darwinian micro-mechanisms of search and selection, as adapted to the social context, that have now become an accepted part of social science (cf. Nelson and Winter 1982, or Elster's treatment of selection, 1989) are also strongly represented in our model, albeit in novel forms. It is the "macro-evolutionary" component of this project, that raises larger questions and deserves closer scrutiny, because it paints, in broad strokes, a "big picture" of global political evolution in the Comte-Spencerian manner, but with new concepts and in a way that also requires Darwinism for its validity.

All in all, this does not imply that evolutionary biology (as well as physics, and cultural theory) and the social sciences must have an identical evolutionary theory. The question is not: how much like biological systems are social systems, or how much social behavior is rooted in biology. Nor is that question part of the debates that have centered around Social Darwinism (cf. Campbell 1969), even though it is fair to assume, (without taking on a commitment to biological determinism), that social behavior has a significant biological component.

Instead the question is: given that the theoretical basis of biology is micro- and macro-evolution, in the sense that both change, and directionality are essential components of evolutionary theory, what additional useful analogies might there be for the social sciences, if the social system of the human species, *mutatis mutandis*, is viewed as subject to evolutionary processes. There are important differences between biological organisms (not to mention the physical universe, and culture) and societies, and they argue for keeping, at this stage, the several realms analytically distinct.

There is also the consideration that the structures that undergo change are not unitary but differentiated, in the case of the social sciences, at least into those of economics, politics, society, and culture. Accordingly, there is not only evolution of each of these structures to be considered in their own right, but also the relationship among these evolving structures, each proceeding at their own pace, but sensitive, and adaptive to, developments in each of the other processes. That is not a problem (how the evolution of one species affects that of others) that is apparently much or commonly studied in biology. Hence the problem of coevolution: how change in one set of social structures and its direction relates to the others. That is why coevolution may be added to macro- and microevolution.

Rational choice v. evolutionary paradigm

Evolutionary paradigms for social sciences embody no claim to universal solution for every problem. They are fitted to deal with some important problems, but are not necessarily the prime remedy for many others. Ultimately, and in the long run, the various paradigms should be mutually compatible, being attempts to study the enormous elephant of social life from a number of different directions. But in the shorter run, such compatibility may not be immediately attainable.

In the social sciences to-day one important paradigm is that represented by rational choice theories (cf. Elster 1989). It has an excellent pedigree, and a fine methodology, contemporary neo-classical economics being one of its successful incarnations. How does it contrast with evolutionary theory?

Most basically, rational choice is the study of decision, that is, of actions to be taken in the light of given preferences, and constraints. Its time perspectives are those of the rational decision-maker, which might often be severely discounted by lack of knowledge or limited by short time horizons. Even more fundamentally, rational choice theories offer no purchase on social structure or structural change, and have difficulty with processes that have time and directionality as their essential characteristics. Neo-classical economists have not had much success in dealing with long-term economic development, structural unemployment, and turn-over in leading sectors. In political science, neo-realists have had some trouble coping with structural change at the global level.

In other words, rational choice theory might yield better insights in the analysis of individual decisions and policy choices, but evolutionary approaches should give superior results in the study of long-range social processes, and of structural change in particular. Evolutionary approaches do not require the postulate of rationality; they allow for the possibility of trial and error solutions by social selection. But they also supply the context within which policy decisions must be formulated, just as micro-choices provide a sound basis for the understanding of great movements.

Such an approach places both "ends" and "means" together at the center of analysis. Both values and ideas, and power, both idealist (agendas, free societies) and materialist (politico-strategic, and economic) components of social processes are equally implicated in this analysis. This is not just a case of trying to have it both ways, in the manner of eclecticism, but rather a deliberate strategy to cover the four dimensions of enduring social experience /5/.

What needs explaining?

What problems in the study of world politics are particularly suited to an evolutionary approach? Global politics evolution might be defined as the theory accounting for the appearance of political organization at the global level, and the processes by which global political structures have acquired their present form. Therefore the short answer is: structural change at the global level which changes, via mechanisms to be determined, is the global political system, and the process is shown in Table 1 as a sub-set of (world) political evolution. /6/ Not nation-states, not countries, but the global political sector of the world system.

Moreover, if a distinction is drawn between institutions (the rules of the game), and organizations (the actors or players in that game, pursuing strategies) (as does e.g. North 1990), two kinds of change will be recognized: in major actors, and in basic institutions of global politics. A most prominent instance of change in actors over the most recent 500 years have been the rise and selection of successive world powers (the most recent being that of the United States) that has provided the basic pulse of global politics.

The other, longer-range process has been that of institutional change. A superficial glance at world politics suggests to some onlookers nothing but a chaos of perpetual 'coming and going' but in fact there is a pattern to it: the succession of world powers not only involved successful copings with a parade of global problems, but also powered basic institutional change. For in the past one thousand years, global politics has moved steadily on a path toward greater global

organization, beginning with failed attempts at world empire that overshadowed the earlier centuries of world system history, continuing with the rise of the nation-state system, and moving increasingly into forays toward world organization that are also likely to extend considerably into the future. In other words, in taking a long view of world politics, we can perceive not just changes in factors, but also changes in basic institutions.

The outline of that process portrayed shows a succession of leading powers, central to global politics of their time, and grouped into blocs of four, each representing periods with characteristic forms of global organization. The first period, Eurasian-centered, is that of the establishment of preconditions, and its defining feature, the failure of the Mongol design for world empire. The second period, West-European in spatial orientation, shows the laying down of a nucleus of an emerging global system in that area, with world-wide repercussions. The third period, opening about 1850, is the start of global political organization, seriously taking off after 1945. Each period marks a transition to new institutions, and new rules of political organization.

Students of this field therefore confront the fact that global politics is subject not just to routine processes, but also to substantial and continuous structural change at more than one level and the basic question becomes: what explains such change in the past millennium so that the process can be projected into the near future? For in that millennium (a) the form and substance of global organization has changed substantially (i.a.) from a condition of minimal or non-existent structure and low connectivity, to one of substantial structure in conditions of substantially higher connectivity to-day. Moreover, that development has been not merely one of change but has also shown (b) directionality (rather than randomness) in that the change has embodied search for innovative forms of organization (appropriate i.a. to an expanding population), and has also traced an orderly path in space, and exhibited a temporal structure.

Put differently, significant aspects of world politics have been about institutional innovation, and about mechanisms and agents of such innovation. Because global politics has been subject to an evolutionary process, an evolutionary paradigm is likely to afford the best answers to questions about that process, and justify some confidence for projections into the future. Such a paradigm accommodates and privileges (diachronic) studies across time, as in long range processes, but also requires (synchronic) at-one-point-in-time studies of conditions that favor and govern evolution.

All this represents the claim that theoretical (Darwinian) biology and the theoretical social sciences are "equivalent, albeit different examples of the use of one and the same general theoretical calculus (or model), the theoretical structure of which remains the same" (Schmid 1987:82). Arguably, therefore, this same model aids in understanding social processes and structures in general, but in the formulation here attempted, the basic propositions of evolutionary theory will be specified as applicable to global political structures. It is these evolving global structures, and not individual polities or societies, that are the subjects (or unit) of the evolutionary process.

EVOLUTIONARY GLOBAL POLITICS

Let us propose here, in respect of global politics, a process model of evolutionary change. A process is a sequence or string of events, and we fit the global political process into the causal structure of the world that we take to be an evolutionary one.

It is a process model because it singles out for emphasis changes over time rather than static "stages of development" that such changes might be said to be bringing about. But allowances are also made for a multilevel analysis both of change of actors, and of change in basic institutions of world politics.

As applied to political events at the global level, the process model consists of four sets of basic expectations:

1. The global political system is a population of strategies.
2. Global politics is a complex system that evolves in specifiable conditions.
3. Accounting for global political evolution is a learning process of which the key operators are variation (innovation), cooperation, selection, and reinforcement.
4. Global politics coevolves with global economics, community and opinion (etc).

These are the basic propositions that comprise the present evolutionary paradigm; they might be called the "hard core", in Imre Lakatos' sense, of this evolutionary research program. Taken together, these four propositions offer a framework for the explanation of structural change in world politics.

1. Global political system as a population of strategies

The starting point for evolutionary analysis is the global political system viewed as a set of policies (or strategies) for the (collective) management of global problems. These policies may (conceptually) be carried by a variety of actors or agents: world empires, city-states or nation-states exercising, or aspiring to, global leadership, alliances and coalitions, international regimes, and world organizations. But the emphasis at this point is not on actors (that afford the ingredients for policy) but on the policies themselves viewed as sets of instructions, or programs of global potential.

The instructions embodied in global policies provide the basis for the standard operating rules, or routines, of the global political system. Such routines reproduce themselves through processes of socialization and training. Variation and innovation in these routines is the material for global political evolution, and occurs as generations of policies succeed each other.

That which experiences global political evolution is the social organization of the human species. Which makes it clear that nation-states are not the basic units of world politics, even though certain nation-states may at times be carriers of global policies. That also means that policies of nation-states such as the United States, or Japan became principal units of evolutionary analysis only in so far as vehicles or indicators of global political change. Their evolutionary fitness, if any, is a component of the global process. Similar considerations apply to evolution viewed regionally, or locally, whose operation should be specified in relation to the global level. It

might be supposed that the working of evolutionary processes is most marked at the species level.

2. Complex systems evolve

Most basically this argument rests upon the conjecture that the global political system is a complex system, and therefore it evolves. The explanation of the evolution of global politics rests upon the global political system belonging to a larger class of phenomena, that of complex systems, all potential subjects of evolution. The argument has two aspects: global politics evolves because it is a complex system; it evolves when "necessary conditions" are best satisfied.

Complexity

The directionality of evolutionary politics is that which Davies (1984:239-240) calls "organized complexity". The basic distinction is between complex systems, and others that may be either orderly, or chaotic. Ordered (or equilibrium) systems follow a fixed pattern and have no flexibility or capacity for change; chaotic systems are disordered and unpredictable. Complex systems stand at the "edge of chaos" but are not themselves chaotic; they have sufficient capacity for change to adapt to new conditions. That is, in the present case, it is the argument that world politics is neither an equilibrium (or near-equilibrium) system, as postulated in traditional "balance-of-power" accounts, nor is it anarchic, in the sense of being chaotic, but is in fact fluid, far from equilibrium, and flexible, one in which order arises through fluctuations /7/.

Complex organization of living organisms can be shown to arise spontaneously given the existence of an *ensemble* that is a large collection of similar systems. Complexity has been defined as the ability to make transitions, that is to evolve. According to Murray Gell-Mann, a "complex adaptive system" is a collection of simple parts that interact to form a complex whole capable of learning about, and reacting to, the outside world. (8)

In the present case, the relevant collection is the population of strategies or policies, past, present, and future. That way experiments will occur with alternative strategies until, in favourable conditions, innovation comes along that is selected out and then cumulates through amplification. The accumulation of countless innovations, large and small, leads to systems as intricate as modern market economies or free democratic communities.

To show directionality, or future-orientation, or "naturalness" there is no need to embrace determinism or assume "progress", as in "evolutionism"; but to postulate only that the evolutionary process unfolds in accordance with an inner logic and/or sequential structure, in that each phase creates the conditions for the next, always responding to new conditions in the environment. Such a process requires some capacity to anticipate the future but no greater motivation other than "search for a better life", or as Adam Smith put it, when accounting for what prompts humanity to save, the ever-present "desire for bettering our condition".

A complementary assumption is that of "sensitive dependence on initial conditions": that the beginning forms have an important effect on the course of development, in that they help cumulate the results of early changes, a basic reason why to examine carefully the time path of

structural change that we also think of as path-dependent. David (1988:18) describes processes whose outcomes are path-dependent as those dynamic processes in which the position and motion of the system, and its constituent sub-systems, are "sensitive to initial conditions". They are characterized by non-ergodicity (they do **not** pass through all the states compatible with its energy in the course of time) and irreversibility /9/. Both path-dependency, and future-orientation are ways of saying that the processes under study have a temporal structure.

Conditions of evolution

If it is now established that complex systems are both path-dependent, and future-oriented, the questions then becomes: what are the optimum conditions required for the occurrence of evolution?

Even though there is no need to invoke the postulate of progress, there is no reason to believe that evolution is a random process, a matter of lucky accident, or "manna from heaven". Rather we suppose that in the presence of certain conditions political evolution (or political learning) will tend to occur. For Charles Darwin, these conditions included Malthusian population growth, and certain environmental conditions. According to Ervin Laszlo (1991:110) "evolution is not an accident but occurs necessarily whenever certain parametric requirements have been fulfilled". These are for complex systems: openness to energy flows, diversity in components, catalytic cycles, and feedback. A chief characteristic of complex systems is heterogeneity.

What might these requirements be for social systems? In respect of global politics it has been argued (Modelski 1987, 1995a) that the necessary and sufficient policy conditions for the rise , that is selection, of one nation-state to leadership in the global political system in the past half-millennium have been: politico-military organization of global reach; lead economy; a cooperative society; and openness and responsiveness to global problems. These are (local) conditions that made it possible for some nation-states to get ahead of others in the competition for global status in a heterogeneous world system. To the degree that long cycles have been the drivers of political evolution, these have also been the conditions of institutional development. Thus they also serve as guides to policy making, and to institution-building.

More broadly speaking they are also conditions that apply to the evolution of world institutions, and to global political evolution in the next century; the nearer the global system approximates, not uniformly but at least in some of its regions, such conditions, suitably generalized, as adequate political organization, matched by a world economic infrastructure of a maturing world market hospitable to the rise of new lead industrial sectors, in the context of an emerging global democratic community, and while responding to global problems, the more likely is political evolution to proceed at a smooth and measured pace. Even more generally these might be argued to be the conditions of evolutionary development in all dimensions of society.

Thus it is important to specify these conditions with some care. All in all there is no denying the most basic postulate of this approach that political evolution **necessarily occurs** in conditions of complexity. That also means that this is not an attempt to explain evolution as the generation of complexity, nor seek to measure its progress by that yardstick; rather to take social evolution to be the property of complex systems that, as occasions and conditions demand, may grow more or

less complex, but that flourishes best in certain specifiable conditions. It is the elucidation of conditions hospitable to evolution that is a first priority of the evolutionary theory.

Questions

What expectations does this set up in respect to our field? Most basically, that global politics is subject to an evolutionary process: that it is subject to evolution, and capable of evolution. Global politics is not, and has never been since its inception, frozen into a stasis of a system populated by "preformed" states of unclear origin and uncertain future. Rather it is the constantly changing global political system of the human species with some parts of it evolving at faster rates than others. Within it, distinct policy lineages or lines of descent can be distinguished that carry the evolutionary process. An evolutionary tree of world political development might clarify such concepts; it would assert the common descent of populations of policies, and their common origin via a branching process (of differentiation). That is why we might view the evolution of the entire world system world as one process (Modelski 1995b).

Pre-evolutionary biologists regarded each individual species as created "preformed", that species were immutable productions, and had been separately created (Aristotle having originally posed the question whether the embryo was preformed, a miniature individual, or differentiated from an amorphous initial state). The preformation doctrine was widely held until early in the 19th century when epigenesis (development involving gradual differentiation of an initially undifferentiated entity) was finally demonstrated by Karl von Baer. It now "stands to reason" that students of world politics can no longer start with "preformed" states as basic units, but must fine-tune their analysis in light of the long-term variability of political institutions by refining the conceptual equipment that bundles change.

3. Evolutionary mechanisms

The third proposition proceeds to conceptualizing the working of this process over time; it asks how and why, what are the mechanisms, and replies, in terms that reach beyond Darwinian analysis, that the basic evolutionary operators are four: not only the Darwinian staples of selection and variation, but also cooperation, and amplification, that jointly constitutes a coherent set. They do not operate haphazardly but appear in sequences that extend over time and constitute learning processes. /10/

Selection is, of course, the classical Darwinian mechanism, so much so that some discussions such as Elster's (1989) convey the impression that it is the only evolutionary mechanism that counts. But Darwin himself gave equal billing to variation, being that which sets the entire process in motion, and Walter Bagehot's (1872) early social and political interpretation of Darwinism certainly gave it a prominent place. However, genetic mutation being also seen as an apparently random process, it often occupied a less conspicuous role, less subject to control than selection. To-day, innovation is generally seen as the source of variation in social evolution, and its independent importance is now getting to be widely appreciated.

Emphasis on selection and what some saw as necessary concomitants, "survival of the fittest", conflict and war, jarred many and led to arguments, one of the early ones being Peter Kropotkin's

MUTUAL AID: A FACTOR IN EVOLUTION (1914), placing cooperation at the center of the evolutionary scheme. Robert Axelrod's (1984) simulations showed cooperation not only to be possible among rational egoists, but also to be subject to evolutionary change. Studies of synergy (Corning 1983) have pointed in the same direction. More broadly we might regard "self-organization" as a fundamental attribute of all evolutionary processes, and regard it, as Stuart Kauffman (1995) has argued, as equal in importance to selection. We therefore regard cooperation as one of the necessary conditions of evolutionary fitness, and survival.

Finally, also implicit in Darwin's framework was the notion of selective advantage, or differential survival, the reinforcement and amplification experienced by "selected" programs, as maintained e.g. by Donald Campbell (1969:73) for "retention": "a mechanism for the preservation, duplication or propagation of the positively selected variety". "Operant conditioning ... is clearly an evolutionary mechanism ... a mechanism of reinforcement whereby a habit is selected 'within' a particular organism" (Van Parijs 1981:96). Reinforcement takes place where there is capacity to learn, and is essential to all learning, and so it is to social evolution.

By synthesizing these classic conceptions, the present account suggests not only that the social evolutionary process utilizes all four mechanisms and that all four are its necessary components. /11/ It also proposes that these four mechanisms are closely and meaningfully related to one another, and may be best understood if seen working in sequences, starting with variation, through cooperation and selection, to reinforcement and retention. But even though they are interdependent, their close relationship is often obscured by the fact that each of these mechanisms falls within the domain of a different social scientific discipline. Very broadly speaking, variation "belongs" to cultural studies, cooperation to several social sciences, including sociology, selection raises problems of politics, and reinforcement, of economics. "The attempted integration of these diverse mechanisms in the study of evolutionary processes represents an ambitious and risky synthesis" (Andersen 1994:14).

Global political evolution

The basic units of analysis in respect of global political processes, as previously argued, are not nation-states, empires, or world organization, but persistent global political strategies (or policy routines). We regard forms of global organization, such as world empire, or global leadership, as carriers of tight clusters (or populations) of strategies that may or may not experience change.

Students of international politics are conditioned to think of states, and non-state actors, as the fundamental units of analysis. Such a view might serve as a first approximation, and often suffices as a shorthand expression. But on close analysis it cannot withstand scrutiny.

Organizations such as states use individuals, but they act through policies. The interplay of global policies constitutes the global political system. It is changes in these policies, changes that alter standard operating procedures that need to be subjected to the greatest scrutiny.

The essentials of an evolutionary learning process, or "calculus" /12/ might therefore be formulated as follows:

a) The starting point is a population of global political strategies (or policies) that persist (that is, successfully reproduce themselves). "Persistence" (or reproduction) means the transmission of a

program, or code, or set of generating rules, to the next generation of strategies. Persistence of strategies need not be, in and of itself, problematic for an evolutionary theory, for it is accounted for by the basic inertia of all social systems.

b) Over time, some if not most of these strategies will be reproduced in a routine fashion, by copying; but others will undergo change, e.g. by experiment or chance mutation, or will be proposed as innovations by policy entrepreneurs in response to demands for the solution of global problems. These are the sources of VARIATION that introduce innovation into the population of strategies.

c) In complex evolving systems, innovations will engender cooperative, combinatorial or synergistic (cf. Corning 1983) effects. Strategies that become the focus of effective alliances have a better chance of surviving. Such COOPERATION, combinations and coalitions are more probable in free societies, and are not random.

d) The political and social environment of this population of strategies (and not, in the first place, "nature", or the "natural environment") might then be regarded as comprising a selective factor or mechanism that helps to determine causally which parts of the program will persist, and which policies shall be substituted for by new programs. In global politics, SELECTION has been most directly the product of macro decision, and in the past, those of global war; more generally, for all political systems, elections are the selective mechanism *par excellence*. In global economics, there is the competitive environment of the world market; in global community formation, the contest of ideologies for the building of "model societies".

e) This completes the process of revising the code, and all that remains is REINFORCEMENT, (that is reward, combined with punishment for non-selection) such that the result is a set of revised strategies that are then diffused, via mechanisms of amplification, and transmitted via a system of inheritance, in successive generations of policies.

One example of an evolutionary learning process exhibiting these characteristics is the long cycle of global politics (Modelski 1990, 1995a; Modelski and Thompson 1996. This (learning) cycle is a non-linear process that comprises four phases, each one of which manifests, and brings to the fore, the operation of one evolutionary mechanism. The first of these phases is "Agenda-change," that through "variation" brings policy innovation onto the global agenda. "Coalitioning" manifests the importance of cooperative action in global affairs. "Macrodecision" is the selection process of that system, and "Execution" is an opportunity for amplification, diffusion of innovations, and the building of memory.

But the turnover of lead powers is no more than a mechanism of world institutional change. Such change at the global political level may be reckoned in four long cycles, each cycle (driven by one global power, competing against others) representing a characteristic evolutionary phase of the global politics process, and four long cycles constituting a distinct period of global political evolution. The West European period of global politics comprised of the Portuguese, Dutch, and two British long cycles, might be thought of as having been formative both of the nucleus of the global system, and of the basic elements of the nation-state system, defined by rules of international law (forming what some call the Westphalian system). Each of these cycles might

also be regarded as having activated successive evolutionary mechanisms at the global level: the Portuguese, those of variation through discoveries, the Dutch those of cooperation in creating, with Britain, the nucleus of the global system, and the two British cycles first selecting the new international system, based on balance-of-power strategies, and then amplifying it through industrial and trade expansion. In other words, we observe (as in Table 3) the working of the same four evolutionary mechanisms both on the scale of one world power rising to global leadership, and of the institutional complex of the world polity in formation.

Hence we argue that evolutionary processes involve the same mechanisms in different settings and in different time frames.

That is, the process of changing policies, or institutions, is not homogeneous but passes through a number (four) of distinct and sequenced phases of a learning experience, each strongly linked to one of the evolutionary mechanisms. Such phases are (in one form or another) the property of all social evolutionary processes because they are all learning processes.

Periodicity

A generation is a key temporal unit of evolution, because evolutionary processes are measured in terms of such generations, and generational turnover seems a basic source of periodicity. The measured generations in question are those of policies or strategies. But it might also be assumed that structural change is closely linked to generational turnover, or the coming and going of generations of organisms, and of humans. If a generation is reckoned as the replacement period, that is the interval during which a generation replaces itself, then in (human) social systems the interval is of the order of 25 to 30 years, and is the basic temporal unit of (social) evolutionary processes. Generations, moreover, are basic units of social learning processes. It is these phases, and generational sequences of phases, that constitute the most important material for the analysis of policy and institutional change.

The fact of regularity of the long cycle, and of related global processes, is now quite well documented. What are the explanations of that regularity? In and of itself, it may not be altogether surprising. According to Paul Davies (1984:241, 57) "periodic motion, or oscillation, is perhaps the most widespread example of order in physics"; indeed, "physical systems which display exponential behavior are also likely to display periodic 'sinusoidal' behavior".

The fact of periodicity or oscillation, or better still, a constant rate of evolutionary change, in turn, accounts for the synchrony that can be observed in co-evolution. Both global politics and the global economy can be called "oscillators" because, as shown, they execute periodic behavior. In physics, as in biology, it is now taken for granted that "coupled oscillators tend toward synchrony". As there are reasons to believe that the global political and economic systems are significantly coupled, they might also be expected to synchronize their behavior, and by extension the same argument applies to processes by which cooperation evolves at the global level, that is the processes of global community formation.

All this poses the question as to the mechanism of such regularity, and suggests the intriguing hypothesis of a social-evolutionary clock. A lead in this matter is provided by biologists who

recently found evidence of evolutionary molecular clocks (in Dobzhansky et al. 1977:308-313, Ayala 1984). Regular changes in molecular structure have been found to pace evolutionary processes over very long time spans (millions of years).

The assumption of a constant rate of evolutionary change (for a given process) is crucial to this analysis. But it is not confined only to molecular biology. That assumption was recently employed with good results in the massive study of the genetic history and geography of the human species, by Luca Cavalli-Sforza and his associates (1994:33). What is more, as they point out, studies of "genetic distance", used to infer when two populations shared a common ancestor, show a close correspondence with, and are supported by the results of, work on linguistic evolution. Indeed, linguists have used the same (though independently derived) logic of a "linguistic clock" (Jones 1993:111) to unravel the origins of the world's languages, the pioneering work being that of Morris Swadesh (1971) who based "glottochronology" (history of the differentiation of languages, on the "relatively constant rhythm of substitution" in a basic vocabulary).

A postulated social-evolutionary clock might be stochastic in character, governed by a constant probability of a certain amount of mutation; at the level of social processes, why not conceive of innovations that might cluster in particular time periods. Such bunchings have been noted in the literature on innovations, and have had so far no clear explanation. They might possibly be linked to the organization, in time, of social processes.

Such a clock could also be metronomic, that is timing such change. The determination of calendars has been basic to the emergence of civilization, and also highly politicized. For instance, the succession of dynasties, as in ancient Egypt, or in China, have been clear markers of world time. For centuries, history was written as political history, and as a story of political regimes. The more recent trends in historiography that emphasize social and economic trends, enrich our understanding of the past, but do not negate the "time-keeper" or "time-setter" effect of political processes. Possibly some evolutionary processes, such as the long cycle, might serve to time others.

Nesting

Basic to this analysis is the insight that evolutionary processes and mechanisms operate simultaneously, though at different speeds, at more than one level. As previously argued (also Modelski 1987, 1995a), in respect of global politics two such levels might be distinguished: one is the actor level, at which, in each long cycle, a new actor has been selected for global leadership, or its equivalent. The other is the institutional level, where a global polity process operates, each period of which represents the cooperative search and amplified selection of a revised institutional framework, the adoption of new rules, and the reordering of the constraints defining the system.

That is why the third long cycle shows three periods of the global polity, those of Eurasian Transition, West European, and Post-West European, each of which represents the search for a new set of basic rules, and an evolutionary process of a restructured kind. The nesting of these four-fold evolutionary mechanisms and in particular how each long cycle, of the rise of one

world power, is composed of four phases, and how four long cycles in turn add up to one period of institutional evolution at the global level. At a yet more inclusive level, these three periods of the Global Polity might each be seen as exhibiting the working of the same evolutionary mechanisms at the world system level as eras of world order.

These two global levels are, of course, analytically distinct /13/, but they are also substantially related in a "nesting" fashion on a basis of self-similarity /14/. That is, these processes are structurally similar, but differ in scale and duration. What is more, the greater (institutional) process might be seen to enfold the smaller (long cycles), while on the other hand, the smaller, while nesting within the larger process, might also be seen to drive it.

It is the specification of the calendar of events (or sequences of events) at the two levels of the global process that is the other top priority of evolutionary theory.

Questions

What additional questions and expectations does this discussion place on the agenda of scholarship? First, that world politics is subject to learning processes of determinate structure that are steadily changing it. Second, it tells us that time is a cardinal dimension of that field, and that no event or policy may be considered in ignorance of that factor because events and policies have duration, and sequential order, and call for coordination. Attention to such "temporality" highlights the constancy and ubiquity of evolutionary change, and the importance of synchronization.

4. The co-evolution of global structures

We have shown so far that global political processes can be studied, in the first instance as endogenous, but it is also clear that the conditions that favour political evolution in turn depend on other evolutionary processes that are exogenous to it. In so far as leadership in global politics depends in part on economic leadership, then the lead condition of a candidate economy is a function of its ability to produce global leading sectors (in originating a K-wave); in turn, leading sector expansion nests in yet other exogenous processes (that is, in the same example, in the evolution of the entire world economy, and of the world system). Concretely, British political leadership ca.1700-1850 was the product of the leading condition of the British economy, etc. The picture is complex indeed.

"Co-evolution" is a term referring to "diachronic changes in two or more interacting objects or systems" and Lumsden and Wilson (1981:367) have extended it to include the reciprocal effects of genetic and cultural evolution. In populations of policies we might speak not only of co-evolution of strategies in global politics and economics, but also of policy lineages. The relationship of coevolution also partakes the character of nesting based on self-similarity. We have previously determined a set of conditions that are "necessary" for selection to global leadership, and that will determine the shape of global organization. As just noted, in the case of the politico-strategic structure the relevant process is, of course, endogenous; that organization rises as part of the long cycle. But for the three other conditions recourse needs to be had to a set of conditions that while evolutionary too, are exogenous to the global political process. These

might also be called "interaction effects" because students of international political economy habitually lay much stress on the interaction of politico-military with economic factors. In respect of the lead economy, as just mentioned, we need to consult developments in the global economic system, and inquire into the conditions that are likely to foster new global economic sectors in particular. The "co-evolution of global politics, economics, community, and opinion, shown in Table 2 is a schematic (descriptive) representation of four processes. The third column, previously noted, shows long cycles that mark the rise (and implicitly also the decline) of world powers, and their antecedents in the early modern period. The fourth column shows K-waves that are coordinate with long cycles and that chart the rise and decline of leading sectors of the global economy; these sectors have been both industrial, and mercantile, representing innovative spurts (or Schumpeterian shocks) in economic and commercial organization, centered on the lead economy. Just as the long cycle might be viewed as the mechanism propelling the global political process, K-waves can be seen as the moving element of the global economy; jointly they activate the international political economy (full documentation in Modelski and Thompson 1996).

In respect of social organization, there is need to look into the rise and decline of "model societies", the shifting fortunes of social movements, and the prospects for a global democratic community; the second column of Table 2 shows the "model societies" that (each accounting for one period of that process) have been successively prominent in cumulating for the formation of a community at the global level, and have thus constituted the outline of what might be called the democratic lineage. Each entry also reports the "opposition", social forces in resistance to which emerged the successive members of the democratic lineage, viewed initially as experiments. This process is in effect one of global community formation, community being defined as a framework or pattern of enduring cooperation. /15/ It is community formation because the global community that is yet to emerge, may be expected to do so around a nucleus formed by the experimental societies of recent experience, among whom a democratic lineage might be traced; equally important this community formation is also coordinate with the political and economic processes just discussed. At the most general level, the evolution of the entire global system appears to be paced (as shown in the first column) by changes in the conceptual and intellectual currents that shape the media, global opinion and education.

Table 2 therefore depicts global politics of the past millennium as a co-evolutionary process activated by successive world powers, interacting with parallel developments in economy and community, and also displaying fundamental change at the institutional level. The elements of a global system arose in Sung China after the 10th century, and generated the Mongols' attempted world empire in the Eurasian context. As that attempt failed, the process then moved, from small beginnings of trial, error, and experiment, through the consolidation of a global nucleus in Western Europe, toward a condition of greater world organization in its current post-West-European period. In turn, that process is shown to be supported, at different but symmetric time scales, by related movements in the global economy, and in the structure of the global community. In these respects it also suggests explanations for the collapse of Communism and of the Soviet bloc in Eastern Europe and in Russia in 1989-91.

So much for co-evolution of global structural processes. For an even more complete picture, reference must also be made to developments at regional and national levels. All in all, a

complex task, that opens broad and ever widening vistas for evolutionary theory. But it might be rendered more tractable because the conditions hospitable to evolution (specified in section 2 above) that define and characterise complex systems may be regarded as the initial proxies for these more wide-ranging ramifications.

Questions

How does this discussion change expectations about the normal course of global politics? It makes it clear that structural change at the global level is not confined to global politics but needs to be thought of as in close coordination with global economics, community, and opinion, all of them hanging, albeit at different rates, and with different "ingredients". No longer is it possible to subsume such efforts under the umbrella of "international political economy" alone. Transition crises in the several processes synchronize, and need to be tackled comprehensively. Questions also arise that reach beyond global politics. This entire discussion implicitly proposes, that in its basics and *mutatis mutandis*, that framework might also hold for global evolutionary processes in the realm of the economy, society, and opinion. Not in respect of all the problems that might be encountered, but specifically in respect of those of long-range import and transformational character.

Hence certain general statements about global politics might also be relevant for other social sciences and seen as basic: that for purposes of evolutionary inquiry, the basic unit of analysis is the human species in its political interactions; that global politics, as well as global economy, immunity, and opinion all evolve, and flourish in certain specifiable conditions, those involving variation, selection, cooperation, and amplification; that the mechanisms of that evolution are (four-phased) learning processes of determinate periodicity; and that at the global level these processes systematically co-evolve through coaction and synchronization.

A research program

So much for the "hard core" (in the Lakatosian sense) of the social evolutionary research program in respect of global politics. It is actuated by the conception of the world system as subject to evolutionary process, in particular in regard to world politics, and one that is driven by the long cycle understood as a (phased and therefore also periodic) selection process. This is the heart of the "evolutionary analogy" (see also Pringle 1951). "Analogies are, of course, not sources of proof, but sources of hypotheses" (Campbell 1969:73).

The "hard core" of the program may not be directly testable, but predictions generated from within it may be, and have given rise to a sustained research program. It began with a demonstration of the existence of long cycles as historical-structural regularities in world politics (Thompson 1988). The theory predicted that at the close of each of the past five global wars one power would emerge with a monopoly of sea power, a key element in the politico-strategic organization for global reach that is a necessary condition of global leadership. Research and measurement has confirmed that prediction (Modelski and Thompson 1988). Other research and documentary work confirmed that prediction with qualitative material, and yet other work related to developments at the regional level.

The next stage was the search for explanation, and the advancement of the thesis that long cycles were an instance of an evolutionary process (Modelski 1990, 1995a). Such work has shown that the rise of world powers may be understood as a phased learning process, as predicted by the "evolutionary analogy", and flourishing best in conditions that may be interpreted as those favouring evolution.

A new stage was entered with the demonstration that the global political process (driven by long cycles) is synchronous with the evolution of the global economy (Modelski and Thompson 1996). There are grounds for thinking that co-evolution of a similar kind can be shown with the global community process (as proposed in the second column of Table 2), and evolution of the global system as a whole (in the first column). Another challenge for the evolutionary paradigm is the construction of a calendar of global politics for the 21st century.

AN EVOLUTIONARY THEORY OF CULTURE?

A Commentary on Rose's paper: Controversies in Meme Theory

By
George Modelski

Nick Rose asks the question: if we can intentionally design memes, why do we need an evolutionary theory of culture?

Let us discuss this problem with the help of an example. As a political scientist with a special interest in world politics, I think of International Law as the current stock of norms (that are memes) regulating the behavior of states. That is, International Law is the meme-type carrying instructions as to how e.g. an embassy is to be established, and run, or how an international organization is to be founded, or operated. International Law can be thought of as a subset of world culture (the world stock of memes).

If the norms comprising International Law are subject to a force of inertia they might also be seen as self-replicating: in as much as states generally tend to go on behaving in a predictable fashion, in the way established by customary state practice and relevant precedents. Law practice and law schools will transmit the meme-type to a new generation of state operatives. It is useful to think of forms in which International Law is codified, such as treaty conventions, or authoritative manuals or textbooks, as forming the "material" meme-type.

The first premise therefore proposes that, in a `natural' but `social' process, the meme-type will tend to replicate itself. But then how does International Law change, adopting new norms and dropping others? The short answer is: by processes of social, including political, selection.

At times, the process can be a massive one. At the end of World War II, an entire new set of rules establishing norms in fields as diverse as the maintenance of peace, regional institutions, the competence of international organizations, trade, finance and investment, and even health and civil aviation, were adopted by the international community. Viewed overall, this selection was determined by the outcome of the global war that had just come to a conclusive ending. Viewed as a macro decision, the global war was the primary selection mechanism for a new set of international norms, and it was the winning coalition of 1945 that jointly selected this new set of norms. Had the opposing coalition won, a different meme-type, meme-type B, would surely have been put in place.

At more `normal' times, the selection process might focus on one meme at a time. Most recently, the prohibition on the use of land mines has been under discussion world-wide. An international conference that convened to discuss this subject decided to propose a treaty banning such weapons, and the treaty might soon come into effect. The movement that launched this new rule of International Law was surely innovative, and must have involved deliberate foresight, but the process by which such potential innovation was being transformed into international practice was one of extended social selection, involving information campaigns, social organization and coalition-building, conference bargaining and negotiation, and has and will be followed by

voting in national assemblies, and ultimately, in national elections (an election campaign is the paradigmatic social-political selection process).

More generally, proposed social innovations (sooner or later) take the form of memes that are launched on the sea of society so that they either replicate, associate with fellow memes, and brave the challenges of a turbulent environment, or else they sink to the bottom of social concerns and are forgotten. That is, they are either socially selected in, or selected out. The fact of origin of such memes in individual or collective experience does not preclude the operation of social selection processes that ultimately add to, or subtract from, the world stock of memes.

In other words, I see no inherent contradiction between the conscious adoption of memes, and the need for an evolutionary theory that treats the social selection processes by which memes come to establish themselves in society, thus becoming part of culture. That also means that an evolutionary theory of culture has its centre of gravity less in individual consciousness and more in events leading to social-structural reorganization.

AN ALTERNATIVE APPROACH TO GENDER AND CONSUMER BEHAVIOR: MEMETICS

By

TJ Olney

Western Washington University

Gender and Consumer Behavior Conference

June 25, 1998, San Francisco

Abstract

Memetics, a relatively new discipline, provides an exciting tool for the study of social phenomena. It combines the cognitive sciences with our understanding of the fields of evolutionary biology and epidemiology. The memetic approach to a subject area allows a non-traditional view as to how that subject has evolved and continues to evolve. Gender provides a marvelous application of the memetic concepts as it is a phenomenon clearly originally rooted in Darwinian survival issues, but one which has just as clearly socially outgrown prehistoric imperatives.

This paper is a Mind Virus that will attempt to infect the recipient with the meta-meme of memes and additionally to suggest how this conceptual framework can provide insight into problems of gender and consumer behavior.

What is Memetics?

"Personally you did not create even the smallest microscopic fragment of the materials out of which your opinion is made; and personally you cannot claim even the slender merit of putting the borrowed materials together. That was done automatically -- by your mental machinery, in strict accordance with the law of that machinery's construction. And you not only did not make that machinery yourself, but you have not even any command over it." -- Samuel Clemens, 1917

Replicating Information Patterns

Memes live in minds as replicating patterns of information. They are thoughts that act as if they have a life of their own. Essential to understanding how memetics differs from other ways of studying human thought and behavior is the notion that it makes sense to say that a meme has its host. The word meme was coined by Richard Dawkins (1976) in his book called "The Selfish Gene". Memes are analogs to genes but of the mental and cultural world rather than the biological world. The study of memes, their mutations, replications, and extinctions closely parallels the study of evolutionary genetics. Thus, it makes sense to talk about successful memes as those that spread to the most minds with the greatest fidelity. The spread of memes within an existing population follows the patterns of epidemiology.

Just as genes can be bundled into packages that infect biological hosts together as viruses or bacteria, memes can bundle into packages known as mind viruses. Mind viruses are composed of mutually dependent memes, analogous to symbiotic relationships in biological settings. Cults provide outstanding and easy to appreciate examples of mind viruses, spreading by proselytizing from cult member to new recruit. Harder to acknowledge and apprehend are the mind virus configurations of enormous complexity that represent such cultural institutions as consumer capitalism, governments, universities, or any organized religion.

If you, in reading this paper, or having listened to a presentation, further investigate the meme of memes and pass it along to someone else, then the meta-meme of memetics will have successfully replicated one more time. Not all memes are as complex as the meta-meme of memes, proverbs and maxims provide a good counter example.

Another characteristic of memes is that they are typically capable of causing behavior changes in their hosts, even if the only behavior changed is to pass along the meme to someone else. So, a joke would be a meme that gets passed along, doing little to change the behavior of its various hosts except that they re-tell the joke. Other memes can have much more profound effects on behavior. For example, a woman holding the meme that "a woman should marry a man who can support her" might choose to marry someone she really did not like because of that belief.

One counter-intuitive result of memetic theory is that a successful meme need not be beneficial to its host. It only needs to be configured such that its host will pass it on. The highly successful memes of astrology and astrological prediction provide an interesting case where there is arguably no tangible benefit to the host, and arguably some harm. Some memes are so virulent that they cause their own self-destruction within the span of a human lifetime. The meme complex of Nazi Germany provides an interesting example (Lynch 1997)

While host benefits are not necessary, most long term successful memes confer some benefits to their hosts, either through enabling or encouraging greater genetic reproduction and subsequent transmission of the memes to offspring, or through preventing the death or destruction of the host by helping them to behave in a life assuring manner. Agricultural techniques provide a simple example of the former case while the "learn to swim" meme might provide an example of the latter. For a meme to have long term success, replicating in many hosts, it cannot have severe negative consequences to its host. For example, the memes that defined Shakerism have essentially died out. Central to the set of Shaker memes was celibacy and no children. Consequently, over time, the rate of adoption of the meme was slower than the deaths of the hosts.

Mutations of the patterns

Like genes, memes do not always replicate with perfect fidelity. Hence, any meme is subject to change as it passes from one individual to another. The joke that changes subtly from telling to retelling exemplifies this phenomenon. The mutation may be accidental as when the quality of the transmission or storage of the original meme fails to be adequate. Or, memes can be intentionally mutated in that are consciously designed by self interested parties. Such memes are often subtle mutations of original memes that had other social agendas in mind. For example, the

cooption by the fashion industry of counter-cultural symbols usually involves some mutation of the original fashion to make them acceptable to a wider audience. The grunge phenomenon provides an ideal example, as the only thing required of the fashion industry was to make the clothes new, and put high prices on them. The pricing alone served to sanitize the dumpster diver look into high fashion.

Categories of Memes

Memetic theory has applied some of the standard memes of positivism to the meme of memes.

One such applied meme categorizes memes into types based on their typical functions in the realities of the hosts.

Distinction Memes

These are the memes that we use to divide up reality into the organization that we know. This part of memetic theory is a straightforward outgrowth of years of categorization literature, particularly illuminated by differences in categorization across cultures. The meme of dividing things into categories is itself a distinction meme.

Association Memes

These are the linking ideas that we hold to say that for instance, "After work is Miller Time." They express the relationships between two or more memes. Much copy writing attempts to engineer association memes between existing memes that people already hold and a new meme that causes the person to purchase a product or service.

Strategy Memes

Strategy memes tell us how to behave in a given context to achieve some result. For instance, the strategy meme that says "Go with the flow of traffic, and you won't get stopped for speeding." might inform our driving behavior. Or, "never go to bed with a man on a first date" might inform our sexual behavior.

Resistance memes

Resistance memes are thought complexes that reduce the probability that a host will acquire new memes that could threaten the memes already held by the host. Because of their key importance in meme transmission, these will be discussed in greater detail below.

Meme transmission and replication: the spreading of memes.

Memes spread by communication. That's the short answer. But the communication of memes can take many forms.

Observation

When we see a new thing, or behavior, for example a new fashion, the meme that entails that fashion has been communicated to us. If we adopt the new fashion, or tell others about it, then the meme has been replicated successfully.

Word of Mouth

When someone tells us that something is so, they have transmitted a meme to us that we may or may not accept. To the extent that the meme gets past our memetic defenses, we will become hosts to the meme.

Parental Transmission

Parents dominate the meme acquisition of their children. The children's minds start out devoid of memes, and fill first with the memes of the caretakers closest to them. (Nanny users beware.) For many cultural memes, things that appear only vaguely or not at all, but rather seem to form the texture of reality, parental transmission provides the route. Empirically, it can be demonstrated that religions that promote many children grow faster than those that are silent on the subject, parent to child being the dominant transmission mode for religion.

Outside the family

Peers, bosses, teachers, caretakers, and authority figures with whom people make direct contact also provide a ready avenue for meme transmission by word of mouth. In this area, there already exists a substantial literature on best communication methods for intentional transmission, but not much is said about the characteristics of the messages that will tend to be successfully copied and passed along to others.

Mass media (include books)

The rise of mass media, along with increasing population densities, has enabled extremely rapid transmission of new memes and variants of older memes. In particular, radio has been singled out as a particularly effective medium for transmission of political memes because the radio audience often consists of people listening together at work. (Lynch 1997)

Evangelism

A meme can be considered to be evangelic if it includes *as part of itself*, the idea that it is important to tell other people. Hence, when the meme of an impending hurricane reaches a certain place, all residents will be likely to evangelically spread the word to any who might have been out of the normal information loop. When someone enjoys a novel kind of sexual behavior, and attempts to convince others to participate in that behavior with them, evangelism is at work. Similarly, people who consume some brands (e.g. MacIntosh) will often evangelically attempt to convince others to consume the same brand. Crisis memes, religious memes, and commercial memes exemplify the class of memes that spread evangelically.

Crisis

Depending on the severity of the crisis, people who accept the crisis's meme are likely to feel more or less inclined actively and effortfully spread the meme. Contrast the impending hurricane to the crisis of ecological disaster following years after the harvesting of a rainforest.

Religious

These are the memes we generally think of as evangelic, hence the term. The admonition to go out and save others with this meme or mind virus is part and parcel to the message.

Commercial

To the extent that a commercial establishment can successfully generate either positive word of mouth about its offering, or negative word of mouth (about the competition or failure to adopt the offering), that commercial interest has designed an evangelic meme.

Issues in meme spreading

Rate of Spread

As with germs like viruses and bacteria, memes spread by communication from one host to another. If the meme contains a sub-part that says that everyone should be sure to pass it along, it acts the same as the sneeze does for the common cold virus. Density of population also affects spread rates, as well as type and availability of mass media.

Intention

An aspect of memetic transmission just beginning to be explored surrounds the question of purpose or intention of the host. This perhaps provides the most direct link to marketing, if not consumer behavior, as producers of products use engineered memes in the form of advertising to attempt to consciously increase the adoption rate of the meme represented in the product or service being advertised. In a very real sense, the offering of a company, that includes its advertising is a set of symbiotic memes that have been intentionally designed to spread. The skill of the designer will affect the transmission rate, the repeat rate and the meme adoption rate. These will of course be affected by the size of the promotional budget and the effectiveness of public relations team in securing additional exposure for the memes.

Indirect meme transmission

There are times and kinds of memes that pass from host to host via rather indirect means, either lying latent in the minds of their hosts, or lying fallow as a hidden text. One such case, that of generation skipping, provides food for speculation about how other such memes might propagate. The example given in several sources cites a tendency for lenient child rearing practices in one generation to be followed by strict child rearing practices in the next generation and a subsequent reversion to lenient practices in the third.

Fallow ideas in forgotten texts, such as the genetic ideas of Gregor Mendel which were ignored until many years after his death, or religious writings of the Druids, can be "rediscovered" and lead memetically rich new lives.

Susceptibility of host

The acceptance of new memes by any one individual depends to a large degree on their susceptibility to the new meme. Susceptibility depends not only on the nature of the meme, but also on the state of the individual in terms of currently held memes. Just as people's biological immune system provides mechanisms for resisting many infectious agents, a mind develops a memetic immune system that protects it from invasion by "foreign" memes. Hence, most mature minds resist colonization by most new memes, but some memes have characteristics that make them more virulent and better able to take residence in any mind, regardless of immunity.

Preexisting Meme set

The degree of compatibility with an existing set of memes strongly effects whether or not we adopt them. This phenomenon has much empirical support from the persuasion literature.

Resistance memes

There are two memes, faith and skepticism, that most of us acquire at some time, that by their nature, act as a sort of memetic immune system for the rest of the memes that we hold against any potentially disruptive memes that we encounter. A third category of resistance meme, the taboo, appears much more explicitly in some cultures than in our own, but taboos do exist at many levels of analysis, from individual, through family and social group, to general cultural taboos. Adversative memes form a fourth type of resistance meme, using intimidation as a primary means of suppressing competing memes.

Faith

Faith represents any meme that you believe without question. Because you accept it as reality, it is very resistant to attack or modification by existing memes.

Skepticism

Skepticism forms a shield against new memes that can be just as potent as faith. With skepticism built into our meme set, we take nothing at face value, but seek further verification of new memes and their potential value. Cleverly composed memes, however, can and do slide right past our skeptical barriers. The scientific method forms perhaps the penultimate skeptical meme set, providing a strong shield against adoption of new memes without adequate evidence, much to the dismay of aspiring doctoral candidates.

Taboo

Any subject that generates a response like, "We really don't like to talk about that." represents at least a mild taboo. The existence of taboo memes provides a passive form of resistance whereby not talking about something makes it harder to pass along memes related to the taboo, hence the first memes to colonize a mind, usually transmitted from parents, have a survival advantage. By forbidding discussion of certain topics, each taboo acts as an antibody against a small set of memes. Often, taboos find very little positive expression, but rather are propagated by negative sanctions surrounding discussion of the taboo subject. While the taboo does not directly counter the memes that it is set against by replacement or competition, the taboo generally slows the spread of the circumscribed memes. Taboo, however, may have interesting side effects, planned or desired by the agencies setting them up as taboo. For example, a taboo against talking about sex and sexuality, including birth control, tends to be associated with a higher incidence of unplanned pregnancies. (Lynch, 1997)

Adversarial/Intimidation

The last form of resistance meme, the adversative meme, sets up an automatic adversarial position in its own host against competing memes. In doing this the host of competing memes becomes intimidated by the holder of the adversarial meme, thereby suppressing any communication of the competing meme to the holder of the adversative meme, and in extreme cases, suppressing any communication of the competing meme to any other potential hosts. Most memes that advocate the incarceration of a particular group use this adversative form to gain

reproductive advantage. The advantage comes not from better replication of the adversative meme, but from the suppression of the replication of competing memes through mechanisms of intimidation. Usually, the espouser of memes competing with the adversative meme finds themselves in the uncomfortable position of being accused of being exactly what the adversative meme is trying to eradicate, be it communists, feminists, gays, lesbians, or intellectuals.

Hot Buttons

One controversial assertion made by some authors writing on memetics contends that we have certain hard wired and early wired kinds of memes that have at their roots survival of the species and of individuals within social group. (Brodie, 1996)

Primary Hot Buttons: the four F's

Any meme will command at least a modicum of attention if it somehow deals with one of biology's four f's, food, fighting, fleeing, and ... finding a mate. As a species we have learned, perhaps have it genetically/chemically encoded that these are important things to attend. They all involve states of emotional arousal related to hunger, anger, fear, and lust. Because of this, memes that use one or more of the four f's as integral parts of themselves will have a greater chance of being received by a new host.

Secondary Hot Buttons

In addition to the four f's, memes that tap into the realms of belonging, identity, approval by others – including those in authority, and caring tend to transmit easily and replicate faster. This in particular forms a rich area for research that links the persuasion literature with the memetic way of viewing problems.

Physical and emotional state

The classic case of enhancing susceptibility to new memes by manipulation of emotional states comes in cult and military brainwashing, where by means of deprivation, and sometimes pleasure/pain techniques, individuals are "programmed" with the desired new meme. To a lesser degree, anyone can be caught with their guard down, and find themselves agreeing to memes and even replicating them without having so intended.

Value of a Memetic Approach to Gender and Consumer Behavior

Aside from being an exciting way to think about thinking and behavior, memetics provides some additional, more rational incentives to its use as a conceptual framework for dealing with gender issues..

Breaking out of our box of using SEX not gender

Perhaps the single most important contribution that memetics offers the study of gender is a way to break out of our box of thinking about gender in terms of sex. With a few notable exceptions (Fischer and Arnold, 1994) most research directly involved with consumer behavior and gender measures sex and not gender. By examining the various memes of gender, and how they are interrelated, we gain a perspective that truly examines gender as a *social phenomenon first*.

Understanding how gender ideas spread

Memetic approaches must necessarily include the *arbitrariness* of a particular meme, and look

not only at its value to individuals, but also at its *fitness as a meme*. Does it resist mutation? Is it passed along to offspring? Is it passed along evangelically? Memetic approaches can begin to answer questions about what makes some ideas anathema to some, while being quite acceptable to others.

Explaining how gender ideas change.

It is clear that people hold many differing ideas of gender, of gender roles, and hold differing attitudes toward gendered subjects. How those ideas came to hold sway in one individual, how certain groups have adopted one set of ideas over another, or how one group comes over time to split off from its parent group are all questions amenable to memetic analysis. When a random change in a genetic sequence occurs that enhances the survivability of the whole gene sequence, we say that there is a positive mutation. Similarly, when a random (either accidental or intentional) change in a set of memes occurs which causes either faster spread or better resistance to competing memes, we have a memetic mutation. Not all memetic mutations will increase the survival of the base meme set. However, those that do will come to dominate the original meme set. The precise mechanism for mutation of memes can be intentional, motivated by biological or economic imperatives, or it might be accidental, caused by a misunderstanding or faulty replication of the parent gene.

A possible example of such a faulty transmission of gender role memes would be the individual who has at once embraced "traditional" gender roles that dominated during the 1950's and also embraced newer feminist ideas of equality and interchangeability of gender roles. The former memes were transmitted to them by parents, while the latter memes have been spread by evangelism through friends and teachers. If the person is a woman, for example, she might have taken on the masculine role of providing income to support a household and found a stay at home man to care for their children. The man, to participate in the arrangement, will have adopted similar memes. Now, the reality that the woman still feels compelled to do the housework and to spend a great deal of her non-work time caring for the children and the man's feelings of inadequacy for not being a breadwinner, represent a faulty transmission of the feminist equality memes to both parties. (c.f. Mahoney 1996)

Explaining resistance to change cybernetically

Feedback loops between existing gender notions, commercial interests, family interests, and gender memes that people choose to adopt or pass along *reinforce* existing memes to the disadvantage of new gender memes. Advertising in mainstream "women's" magazines provides the perfect example of this reinforcement phenomenon. Women who read the magazines pick them up because they believe there will be value in looking at the magazine and because they think that the particular magazine fits with their sense of who they are. The magazine then reinforces certain ideas of gender roles and behaviors, to the exclusion of other ideas. The feedback loop continues if friends talk about the ads or articles and agree with the advice or fashion ideas.

Facilitating multiple conceptualizations of gender

As a way to allow true multiplicity in definitions of gender, gender roles, and gender orientation, memetics has no peer. The biological analogy of species provides us with different gender species that really don't have much to do with one another except to see the other as a threat or as

a possible symbiotic partner.

Possible pitfalls of a Memetic Approach to Consumer Behavior

The Nothing New Syndrome

As is often the case with new ideas, they are mutations of already existing ideas. Memetics suffers this and doing work based around memetic themes exposes the researcher to the skeptical resistance memes of journal editors and department chairs. The biggest danger of these resistance memes stems from the inherent bias to defend existing (held by me the reviewer) memes against all comers. To overcome this, we need to acknowledge that for Consumer Behavior, these ideas have their roots in existing social science theories. Simultaneously, we need to emphasize the benefits to be gained from the "new" parts, those drawn from genetics and epidemiology.

The "Not Science" syndrome

Memetics, as an infant discipline, and one which seeks to be a meta-discipline, threatens many in social sciences as a usurper. The understandable reaction of many has been, and will continue to be dismissal out of hand, as not science. The greatest difficulties lie with definitions and with a lack of generally accepted methodologies for empirical research. More than most paradigms, memetics is fraught with possibilities of indeterminacy, as the act of observation changes the state of the system.

Holds itself as a purely positivist paradigm

Even while subject to criticism from those calling it not science, people working in memetic areas seem to be predominantly positivists, bent on objective reductionist explanations for phenomena. This seems to extend to the fact that most will not acknowledge science or the scientific method as memes in their own right. This typical semiotic difficulty of framing one's own paradigm as natural makes unlikely any cooperative collaboration between memeticists of a positivist stripe, and memeticists more comfortable with a phenomenological approach to explanation.

Avenues for research in gender and consumer behavior using memetics

The Memes of Gender

Gender memes quite simply constitute the set of beliefs that anyone holds that cause them to behave differently because they are xx or xy and to behave differently toward xx or xy people. Also included in the set are memes about the roles of people other than one's self that one deems as appropriate because of the genotype of the other person. Notice that this does not preclude masculine xx's or feminine xy's, but merely puts a large boundary around gendered memes. "Appropriate" means of course, in the mind of the person holding the meme, and does not cast any social value judgment on anyone's behaviors. Each individual will filter the behavior of others and their own behavior through their own gender memes. Included are all "appropriate" behaviors, all "appropriate" possessions, and all relevant strategy memes as to how they should behave to accomplish their own ends in the context of a world constituted of xx's and xy's.

The description and mapping of gender memes, and more particularly consumption memes with gender components, provides the most immediate application of the concepts of memetics in the

field of consumer behavior. No list that included here could possibly be complete, (What are you wearing today?), but a few examples might illustrate the potential of memetic research into gendered consumer behavior.

Investigating Gendered Distinction Memes. The simple questions of what constitutes appropriate behavior given xx or xy chromosomes and what possessions and consumption patterns are deemed appropriate have caused endless debate among scholars and lay persons alike. When viewed memetically, these questions yield to some fairly straightforward analysis. Some analyses like this have already appeared in the literature (Brodie, 1996, Lynch 1997) but there remain many gendered consumer behaviors that have yet to be so analyzed. Furthermore, existing analyses practically invite refutation and rebuttal. The questions answered here will relate to how people divide up the world into male/female masculine/feminine and how those divisions change over time in response to mutations of these distinction memes

Cataloging Gendered Association Memes These memes of gender probably cause the most heated debates amongst otherwise likeminded people, as they are the ones that link or associate xx and xy genotypes to what we commonly have called attitudes. So, when a meme spreads around that "boys will be boys" or that "girls are sweet" or any other common cliché, we have a gendered association meme. The extent of these kinds of memes in the population should be documented and tracked over time.

Cataloging Gendered Strategy Memes Probably the most problematic of issues that face people in a world of ambiguous sex roles and diverse definitions of gender are those that deal with how to get what they want vis a vis mating and survival. Strategy memes are those that provide rules for behavior under certain conditions. The strategy memes surrounding, getting all the sex you desire, the children you want, and the standard of living you desire have changed dramatically over the years, especially since the invention of reliable birth control in the form of the pill. Where once "The Rules" (Fein and Schneider, 1996), might have been well accepted, they are now rejected by most.

Examples of gendered strategy memes that bear investigating follow:

In order to get the kind of life that you want, find a _____ to _____ you.

Follow the "rules."

Men should never _____.

To get what they want women should _____.

Your clothing should accentuate your masculinity/femininity.

Study of mutations of gender ideas. Memetics provides a venue to examine how variants of successful gender memes either die out or become more successful than the original memes. For example,

Study of socialization to gender. Here fruitful areas of inquiry for consumer research would revolve around such things as how shopping methods and procedures are differentially communicated by parents based on the sex of the child.

Investigations of how consciously mutating gender memes can work to change behavior.

This now takes us into the realm of investigating memetic engineering. An area that those in the field of memetics seem to think we should be intimately familiar with as consumer researchers are often associated with marketing departments. Study in this area can provide us with empirical evidence as to which characteristics of memes do the most to facilitate accurate transmission of memes. We also need to study which characteristics of memes facilitate rapid transmission of memes.

Summary

Memetics provides a useful reshuffling of our cognitive deck. Viewing ideas as having a life of their own, and characteristics that improve their chances of repeated accurate transmission from mind to mind gives us a new window through which to view consumer behavior problems. In particular, memetics gives us a slightly less emotionally loaded way to speak about inherently sensitive subjects like gender and the role of gender in consumer behavior.

Abstract

Mental representations, or memes, transform the space in which they evolve. Their survival is dependent on the survival of the individuals and the groups hosting them. Creativity - the production of new and useful ideas - is closely linked to the social dynamics of the individuals expressing creative ideas: without social confrontation new memes cannot become diffuse. Creative individuals tend to be emotionally unstable, and many are affected by mental disorders. Studies on the link between creativity and mental illnesses show that it is exactly the characteristics of the mental disorder which also confer some advantage on afflicted individuals. These advantages extend to the groups to which the creative, mentally ill individuals belong. The group comprising the most creative personalities will therefore acquire an adaptive advantage which maintains the integrity of the group as a whole, in spite of the vulnerability of the individual.

Key words: creativity, evolution, meme, mental representation, mental disorders, bipolar disorders, schizophrenia, natural selection, information processing

1 Introduction

Mental representations, or memes, transform the space in which they evolve. In a recent paper on this topic, Liane Gabora stated: "*culture not only affects biological fitness through its effects on behaviour... but it dramatically modifies the biological world*" [7]. Creativity - the production of new and useful ideas - is closely linked to the social dynamics of the individuals expressing creative ideas: without social confrontation new memes cannot become diffuse: "*creativity is a collective affair*" [7].

The majority of studies on creativity have focused on the characteristics which favour it at an individual level, but all researchers are conscious of the social nature of the creative process. It is not easy to define exactly what creativity actually is. To create, per se, implies the production of something new and original. However the qualities which make an individual able to produce new entities are not well understood. As is also the case with the concept known as "intelligence", it is unlikely there is a general creativity factor unevenly distributed across the population. Rather, creativity can be conceived as a complex of qualities that allow some people more easily than others to produce new objects or ideas. As a consequence creativity is often described in relation with the end product, in a way that can occasionally be tautological:

creativity is often conceived as that which has led to results considered creative by general consensus.

Measuring creativity is not an easy task: the methods used in the evaluating of creative aptitude and ability are numerous and as ingenious the argument investigated demands them to be. Summarizing the different criteria used for measuring creativity Dennis Hocevar [10] reviewed ten main categories:

- Tests of divergent thinking
- Attitude and Interest inventories
- Personality inventories
- Biographical inventories
- Teacher nominations
- Peer nominations
- Supervisor ratings
- Judgment of products
- Eminence
- Self-reported creative activities and achievements

Most of these techniques are based on third person rating. Although inter-rater agreement is generally obtained, the problems of "*who judges the judges*", and what the judges should be looking for, remain unresolved.

A minority of methods rest on independent tests of measurement: these tests, like the tests of divergent thinking, are based on specific models of what creativity is, so any consideration of their results is biased by the personal view of the researcher who reported them. However, as in the case of "intelligence", there is probably no way to avoid this dilemma. Ultimately, any discourse on creativity, or any other conceptual construct, must involve a description of the boundaries of the concept discussed.

The description of creativity that is now generally accepted identifies creativity as the ability to create products or ideas which are original and which possess a strong social usefulness. Frank Barron [2], one of the most authoritative researchers in this field, notes that a creative product or idea should be new or original and be acknowledged as such by social consensus: a criterion of usefulness is implied by, although not essential to this definition. In this view "Creations" are products which appear new and are also considered valuable by consensus. To introduce an innovation requires the comparison of the new idea or product with the pre-existing alternative, and the evaluation of the innovative product with respect to existing needs. A creative result can serve to resolve a problem or to satisfy an unconscious aesthetic drive: although this can be experienced at an individual level, in the majority of cases the problem or the aesthetic impulse operates on a social level, and the creative solution must be communicated to others if it is to produce some effect.

Many factors contributing to the expression of creative potential are a reflection of this essential dimension of the creative process: i.e. the need for social testing of the creative product. The proper elaboration of the primary creative effort requires the development and the testing of the

new idea against scientific and aesthetic standards, which are, of course, of a social nature [15]. There are many studies which explore the link between creativity itself and the psychological characteristics of creative individuals, and which, in so doing, shed light on this argument [2,12,13,21].

Generally, creative people tend to emerge as both sociable and popular with their peers; they appear to welcome social contact and show interest in social activities. Creatively gifted people more than their peers also show risk-taking and novelty-seeking tendencies. While this grants them greater independence and unconventionality, it also leads to emotional instability, and in fact one of the most surprising psychological characteristics of creative individuals is their proneness to mental illnesses [10, 11, 12, 13].

2 Creativity and Mental Illnesses

Most studies show that there is a link between creative ability and the risk of mental disorder: in fact the prevalence of mental problems among creatively gifted people is significantly higher than in the general population [2, 11, 12, 13, 15, 21]. A link between eminence in the arts and science, leadership qualities and mental problems was even suggested by the author of the fragment known as "*Problemata XXX*", now part of the aristotelian canon. In this text, many behavioural characteristics are indicated which are peculiar to patients suffering from manic-depressive illness. This would suggest that eminence as result of creative aptitude and madness are linked by a non-casual link.

In the positivistic era, the Italian Cesare Lombroso illustrated this thesis in a circumstantial way referring to the "genius" and the "lunatic" related, in his opinion, by a shared genetic basis [14]. Most studies performed in the positivistic era, in order to either confirm or refute Lombroso's hypothesis, rest on biographical evidence, raising the suspicion that these studies claiming a higher prevalence of psychopathologies among creative or eminent people were biased by overexposure. However even the later studies, performed using methods applying specific nosographic categories and direct confrontation with the candidate through interviews and inventories yielded similar results, with a higher prevalence of mental disorders among gifted people than among the general population [12, 13]. In the majority of studies disorders with an affective (mood) component, in particular those characterized by melancholy (severe depression), were associated with creative achievement, just as the author of the *Problemata XXX* asserted [1, 11].

The disorders most implicated are those with a bipolar trend: i.e. disorders characterized by the alternation of depressive episodes with other episodes with an opposite euphoric mood. In the period between episodes those who are suffering from these disorders have a highly adaptive life style, with generally very high levels of social functioning, thanks to the tenacity, tirelessness and social ease that are typical of these individuals [8]. Nevertheless the disorders can be highly impairing: bipolar patients are often inconstant at work and their affectionate and social relationships tend to be stormy; their divorce rates are higher than those of the general population, and there is a very high prevalence among them of misuse of alcohol and other drugs, which bipolar patients may take either as auto-therapy to lessen anxiety and depression, or during impulsive euphoric periods [8].

Studies on the relationship between creativity and mental illnesses suggest that it is the same characteristics of the disorder, in their less severe manifestations, which confer some advantage on afflicted individuals and their relatives. Ruth Richards, who extensively studied this aspect of bipolar disorders, found a high propensity among bipolar patients and their relatives for the development and expression of creative potential in every field [19]. These abilities were evident mainly among individuals with less impairing or subclinical forms of the disorder.

Among the characteristics that favour creative achievement among bipolar individuals there are some that are specifically related to ability in social intercourse. People with bipolar mood disorders tend to be more emotionally reactive, which gives them greater sensitivity and acuteness. A lack of inhibition permits them unrestrained and unconventional forms of expressions, less limited by accepted norms and customs. This makes them more open to experimentation and risk-taking behaviour, and, as a consequence, more assertive and resourceful than the mean. Sensitivity and lack of inhibition make these subjects warmer and more friendly in social intercourse. Both aptitudes also represent a clear advantage on a professional level, particularly when competition is greater. Being more sociable and less inhibited in expressing themselves, individuals prone to bipolar disorders may manage to spread their ideas with greater ease, allowing their ideas to prevail over others competing for predominance.

3 Creativity, Memes and Evolution

These observations show the importance of the social side of creativity. Creative ideas, like other memes, reflect the dynamics of the individuals who host them. New ideas can therefore find success only when their hosts, and the groups to which these individuals belong, are also successful. In his studies Cavalli-Sforza showed that the diffusion of grain cultivation was directly linked with the spread of the population which elaborated the technique [5]. Another example is the heroin abuse epidemic: where there are no drug abusers there is no heroin to be sold.

As Liane Gabora asserts in her paper: "*the bottleneck in cultural evolution is the capacity for innovation*". Groups whose members possess the ability to make innovative mental associations can take advantage from this, even if the ability is linked to maladjusted behaviour at the individual level. Examples deriving from the studies on the relationship between creativity and bipolar disorders are suggestive. The high suicide rate (10% of patients) and the low fertility of bipolar patients, who tend to marry less than the general population and have less children than the mean, suggest that, both now and in the past, the carriers of the genetic burden of the disorder must have some compensatory advantage in order for a relatively high percentage of affected individuals (more than 1%) to be maintained in the general population [24]). Bipolar disorders have a strong genetic component [16]: people who suffer from them, and their relatives, share some genetic factor which is transmitted from one generation to the next.

Propensity to develop a bipolar disorder can be conceived as a hitch-hiker allele which confers no compensatory advantage per se, but which endures because it is linked to creative abilities important for survival. The bipolar gene may contribute to its own survival in the gene pool by virtue of the resistance, tenacity and energy it confers on the individual, or may favour behaviour

which contributes to its replication. If creative individuals are more likely to assume leading positions in various fields, then hitch-hiker alleles that contribute to creativity would also spread. There are many creative individuals with associated mental problems in the artistic field [11]. Poets and writers seem to be particularly prone to developing mental problems, generally of a depressive type, and it has even been asserted that one cannot write with success without being "exposed to the Dark Sun of Melancholy" [15]. Joseph Schildkraut, one of the fathers of the biological approach to the study of mental disorders, put forward a very suggestive hypothesis attributing a decisive role to artistic symbolism in the favouring of social cohesion of groups.

Thus the group containing the most creative personalities will acquire an adaptive advantage which maintains the integrity of the group as a whole, in spite of the vulnerability of the individual who is subject to depressive breakdowns [21]. This explanation derives from the concept of inclusive fitness, according to which a behaviour pattern under genetic control is selected for its ability to favour the production of successful offspring both by the individuals displaying the behaviour pattern and by their genetic relatives. Group selection has often been thought to favour traits that are individually disadvantageous but evolve because they benefit the wider group [22, 23].

The same results could also be associated with memes (such as respect of agreements or the stifling of revenge) that may be detrimental to the individual but clearly offer an advantage to communal life. Well known example are the prisoner's dilemma and the TIT for TAT strategies*1.

4 Creativity, Schizophrenia and Information-processing

Studies on the relationship between creativity and mental illnesses also throw light on the role of the gating systems involved in information-processing. The creation of new ideas requires combinations and transformations of old ones: we can only hypothesize about what we do not yet know. However, information processing is not a fixed, mechanical procedure. The flow of inputs is guided by centralized systems which regulate the amplitude and length of oscillations in the canals that transfer the information.

Like schizophrenic patients, creative individuals often report odd sensory and perceptual experiences, feelings of restlessness and the inclination towards impulsive outbursts in association with rejection of common social values [4, 6, 25].

Highly creative "normals" also tend towards over inclusive or "allusive" thinking and, as pointed out by Albert Rothenberg [20], demonstrate a capacity to conceive and utilize two or more opposite or contradictory ideas or concepts simultaneously, without being disturbed by this simultaneity of opposition, as is also the case with schizophrenics. It seems that creative individuals, like schizophrenics, are subject to a widening of selective attention, which makes them more aware of and receptive to experience, with more intensive sampling of environmental stimuli [9, 19]. In fact ideational fluency and a preference for complex and asymmetrical designs, two of the main factors contributing to creativity, could derive from higher levels of arousal and faster stimulation of discrete cerebral areas. Schizophrenic thought processes tend to allow unusual associations which result in over inclusive thinking, with many irrelevant elements

being included in reasoning: this peculiar style of thought is assumed to derive from a failure in the filtering of stimuli by dysfunctional gating systems [3, 18]. Creative individuals, conversely, may gain advantage from higher levels of associative thinking, since they are capable of effectively processing these increased inputs without the risk of cognitive overload. Since to create consists essentially of the making of new combinations of associative elements [3], any ability which serves to bring together otherwise remote ideas will facilitate a creative solution [9, 17]. The favouring of associations implies an extended knowledge of the argument under study (memory of ideas to be associated) and a restriction of inhibitory influences on stimulation of remote cerebral areas. The more associations evoked by an element, the more likely it is that another element will be combined with it in a manageable form. Since inhibition or suppression (by anxiety or other more powerful competitive stimuli) would limit awareness and openness to both internal and external stimuli, freedom from these forces would favour associative thinking, and so creativity.

5 Conclusion

One should not ignore that the stereotype of the eccentric artist or of the mad scientist also plays a protective role in the collective imagination. It acts against the fear and suspicion that excellence and the diversity of others always engenders in the majority. The image of madness linked to genius has been repeatedly expressed in the history of the western world. It was codified during the Renaissance in the figure of the melancholic genius afflicted by Saturnian acedia, and underwent a resurgence during Romanticism in the figure of the tormented artist. Creativity is, after all, a challenge to an existing meme pool, since it leads to the creation of competing memes. The stigma attached to diversity may lead individuals to assume even more eccentric behaviour: the definition of such behaviour in terms of "mental illness" may result from "strategies" defensive towards existing memes. In fact it is the pool of existing memes that decides what is good and healthy, i.e. coherent with its own criteria. In addition, some temperamental traits, like eccentricity, uneasiness or propensity to excess and experimentation, which are widespread among creative people, could be a reflection not only of an underlying mental disorder, but also, and above all, of the tolerance on the part of society of the behaviour of famous individuals. In these cases deviant behaviour is tolerated because it allows the expression, by third parties, of dissenting demands which the majority of people are not able to express.

Many issues concerning the "dark side" of creativity remain unresolved. Equally, the same contribution of new memes to their own diffusion is only partially understood. A particular set of productive memes, for example, may exert a selective influence on the appropriate neuronal groups which in turn lead a particularly creative individual to produce creative things. We hope this paper will achieve this same end, conferring a competitive advantage towards an understanding of the creative process and cultural evolution on the memes detailed herein.

*In Campbell . and Duperret Than V. Eds. 1996 Proceedings of the third ECLO Conference,
Copenhagen May 1996*

Organisations and organisms are self-maintaining systems which spontaneously seek to preserve an evolved order. Both are enabled by replicators: memes or genes respectively. Whereas genes are the units of transmission of our biological inheritance memes are the units of transmission of our cultural inheritance. They cause organisations to settle into patterns, routines and habits of behaviour: manifestations of a particular memetic inheritance. These patterns enable the organisation but simultaneously limit its performance.

Both systems share the evolutionary dynamic of adaptive radiation followed by stabilisation. Memetic examples include new markets, new technologies and new business ideas. Business theories and their derivative, managerial fads, are a class of memes. This paper illustrates the increasing returns dynamic in the evolution of management recipes by contrasting Business Process Re-engineering and the Learning Organisation. It ends with a plea for the Learning Organisations to retain memetic diversity rather than be trapped in sterile competitions to define an LO. **The power of the Learning Organisation movement may, paradoxically, be that we are not stuck with what it is.**

IS ECLO ALIVE?

This paper ultimately concerns the patterns of language and thinking which stop organisations, and individuals, learning as fast as they might, thus stunting their growth. Interrupting conventional language patterns facilitates interruptions of conventional thinking and we, intentionally, choose here a different and interrupting style of writing: hence the starting question.

Our hope is that we can extend a different invitation to the reader. We would rather stimulate dialogue and enquiry into that which limits, in any given context, than into the rightness or wrongness of a theory. When so-called learning is no more, or is perceived as no more, than an exercise in intellectual one-upmanship, or when it is a debate among spectators unconcerned

with helping themselves, and others, make a difference, then it is, for us, limiting. Please read not only to enjoy but also with a view to making a difference.

Consider, for a minute, the definition of life offered by the English biologist Richard Dawkins (9)

[Life is]...a property of improbable complexity possessed by an entity that works to keep itself out of equilibrium with its environment.

To exapt Dawkins most graphic example a dead parrot thrown into the air obeys the laws of physics, describes a perfect parabola, and then falls back to earth. A live one disappears over the county boundary; its component parts working together to maintain their collective entity against the force of gravity.

Now - using that definition what is different about a company, or any other form of organisation, including the ECLO? All organisations maintain an improbable complexity to achieve some purpose that their component people and parts, working separately could not achieve. [See (14) (27) (28) (36) for further discussion of theoretical comparisons].

Professor Herman Van den Broek started the ECLO conference series by reminding us *how quickly people adapt to tacit agreements and recreate recognisable settings* (35). We operate to keep ourselves in our own equilibrium rather than succumb to the random decay of the second law of thermodynamics. Yet, in the process, our organisations and sometimes even we ourselves fail to learn. How can we be so stuck in the rich tapestry of our collective achievement? Nothing if not ambitious, we offer here a very simple answer to the riddle.

PARROTS & PATTERNS OF PRESERVATION

Why do we all tacitly participate in structures that we know are not yielding us the result to which we aspire?

Why do we all conspire in corporate behaviours that each of us may admit, privately, are suicidal?

Herman van den Broek's enquiry was one of many which have pointed out how organisations settle into patterns of established behaviour. In a spirit of European integration let us acknowledge that Machiavelli made the same point 500 years ago. Organisations coalesce around rules, habits, traditions, customs, codes, mental models, paradigms, language: shared patterns of taken for granted being-in-the-world. They maintain these patterns as surely as a live parrot maintains the long tradition of parrot-hood. The parrot ultimately has no choice in the matter. It is the creation of a tradition encoded in countless generations of parrot genes. It owes its being in the world to those genes relentless search for their own replication (8) (10).

Not to put too fine a point on the matter, and ignoring only time scale, even those of us who espouse the cause of organisational learning and human choice are usually as stuck with our patterns and traditions as are generations of parrots with their genetic inheritance. Standing for a

different perspective on the world, a different outcome in a company, or even, dare one say, a different presentation in a conference with an established tradition, risks the fate of a "green" in a colony of "*Norwegian Blues*", or of a member of any community who does not conform to the mores and paradigms of membership. Companies reject, conferences have no listening for, and individuals do not hear, that which does not conform to their expectations on the world. It is safer then to talk about learning within an established pattern rather than risk membership. Yet, for a pattern to be changed the risk may be needed. We, none of us, learned to walk without risking abandoning the comfortable pattern of crawling.

WHAT SOURCE THEN THESE PATTERNS?

For the parrot, and every other living species, the source of the pre-ordained order, the root, at one and the same time of the ability to maintain *improbable complexity* and the stuckness in the tradition of a particular species, is very simple. It is the genetic code, the genome of the species or the genotype of the individual. All species, including our own, are lumbering robots created, specified by their genes, to act, and interact with others, in ways that maximise the chances of those genes leaving copies of themselves in the world.

As many are now pointing out [see postscript] the parallels of organisation and organism extend beyond the maintenance of improbable complexity. Both are complex systems that evolve and adapt, that self-organise in webs of complex relationship. Both depend for their survival on strategies, explicit or otherwise that anticipate the future: usually as a continuation of the present. Both depend, for their ability to maintain order on what Murray Gell-Mann (14) has called schemata or Richard Dawkins (8) replicators: codes bent on their own reproduction through the systems they create.

DNA as a genetic replicator provides a biochemical language through which are encoded and transmitted the instructions that enable and specify every complex, self-maintaining, living system (22)(23)(36). The individual gene is a strip, a phrase, in this language that survives because it manages to convey utility to its host in the competition for survival in the organic economy. To do so the gene must act in the context created by the thousands of other genes in a given genome; as words and phrases, to convey meaning, act within the context of the language and tradition in which they are used.

Our starting proposition is simple. It is to take literally Dawkins suggestion that there exists in the cultural world a second class of replicators, - *memes* - transmitted from brain to brain through human language and cultural artefacts.

The distinction meme (10) (27) (28) may not yet be one that has a context in the language and intellectual tradition of many readers. It does not yet exist as a separate perceptual and linguistic entity through which many people view the world. So what is it? In brief:

a unit of cultural transmission that propagates from mind to mind conveying a meaning in the process; a meaning that may mutate each time it is transmitted but one that is captured and remembered.

Any linguistic or other cultural artefact can serve. As Dawkins puts it:

*When you plant a fertile meme in my mind you **literally parasitize my brain**, turning it into a vehicle for the memes propagation in just the way that a virus may parasitize the genetic mechanism of a host cell.*

Tunes, fashions, advertising slogans, phrases, linguistic distinctions, gods, technological recipes, paradigms, mental models, perceptual filters and all the stuff of tradition, language, culture and cognition are memes and complexes of coexisting memes. The advertising industry runs on memes without bothering to explore the fact. Every slogan, every image it creates, is designed to infect the mind and influence the actions of the recipients. Hence its fundamental irrationality (21).

A geological metaphor provides an image of the physiology and psychology of memes at work upon the individual, or collective, mind. Imagine a landscape, eroded over time to provide streams, rivulets, and rivers interspersed between higher plateau. It provides a simple example of a self-organising, locked-in, system. Over time accumulations of rainfall carve out stream and river beds and settle into pools and lakes. Any new rainfall will no longer find its own way but will rather take, and reinforce, the already sculpted path of least resistance. Though the falling rain may be evenly distributed across the land, in its collection and flow across the landscape, it will tend towards a predetermined route, one taken by previous rainfalls.

Just as the rainfall follows established routes so perception follows established ways of seeing. Technically, even if the light sources which perturb the back of the retina, or the acoustic waves the eardrum, are identical, what will be noticed from all that could be seen or heard will depend on the perceptual lens through which we view the world. What is there is not independent of the receiver. What is there is what we have been trained [or conditioned or have learnt] to see. We may discard, indeed we can be blind to, anomalies that do not fit. The self-organised pattern which we call our thinking grants a particular perceptual blindness and rigidity to our perceptions of the world.

Exploring the analogy further we could say that an idea, a single thought, an utterance, *-a meme in fact*, is like the single raindrop. It falls upon a pre-formed perceptual memescape. Isolated thoughts gather together in a string - a pattern of co-existing memes - which we might compare to a few drops congregating together in a splash of water. With sufficient mass the splash of water starts to flow into streams and rivers which are, if we like, the connectors between the raindrops and the pools and lakes, if not the oceans, of our thoughts. The pools and lakes we may view as concept pools and theory lakes. Thus a self organising system is inherited and developed in which the flow of perception takes a certain course: it follows a certain pattern, a largely given paradigm.

Patterns in companies, habits and rules of behaviour, codes of thinking, systems of language, states of relationship coalesce in similar fashion around shared landscapes of perception (6)(16)(27)(28)(29).

Take this simple idea of memes as a reality in the world and you arrive at an explanation of a plethora of observations from many field of scholarship concerning the behaviour of human systems with self-fulfilling prophecies, self-replicating patterns, mental-models [e.g. (2) and unwritten rules [e.g.(6)(27)(31)] at their core. The **ECLO** is a meme around which a pattern called conference has emerged; a pattern similar to that of many another conference but a pattern with its own emergent tradition of rituals, conventions and unwritten rules of behaviour; a pattern that both enables and circumscribes what we may or may not learn from one another within the context of this conference.

To understand the phenomenon of emergent organisation we should ask not what benefit it confers on the participants but what benefit it confers on the meme. How does the emergent tradition of the conference assist a meme called ECLO infect more minds?

MEME'S EYE VIEW

Dawkins main argument in *The Selfish Gene* is that to understand evolution and its products we should examine it, and them, not from the benefit a particular phenotypic behaviour confers on an individual organism or a species, but from the perspective of a genes [or a complex of genes] replication. We want to make the same point in respect of memes in organisations. From the perspective of one set of memes enthroned in an individual mind, or shared by a collective organization what matters is their replication in meme-space, not the benefit or otherwise conveyed to the host. As Dennett (10) traces, many memes in the paradigmatic landscape of the humanities triggered defensive routines to Dawkins suggestion; an example of the generic "**not invented in my head**" syndrome that inhibits learning at many levels (3).

We want now to demonstrate this switch of perspective by comparing the evolutionary history in the world of two memes; two ideas that have infected the minds of a population of organisational theorists and practitioners in recent years. One of these will, we suspect, be easier for readers of this volume to visualise as an alien virus seeking to parasitise other minds so we will start with that one.

The Bad and the Ugly? BPR as a Meme

Think back some eight years to the late 1980s when the Business Process Movement first became noticeable in management practice and language. Around about then, in most corporations in most sectors, the pressure to extract more value from white-collar activity became overwhelming. The competitive advantage of doing so, and the threats in not doing so, were simply too large for companies to ignore. The environment was ripe for new approaches to structuring work and organisation.

From the flux of variation and mental mutation that is the soup of business theory and practice there then arose several variations on the theme of Process Management seeking meaning space in the new environment. Most could be considered adaptations [more strictly exaptations] of prevailing manufacturing approaches. Most large American corporations and some European ones announced process as a key plank of their strategy for the 90s. As one director of a British company recently recalled to us "*My boss went to the USA and caught the BPR bug*" Yet it was

not then the only bug in town. A brief survey of the popular management literature in late 1990 and early 1991 would have revealed:

- Business Process Review
- Business Process Simplification
- Business Process Management
- Business Process Innovation
- Business Process Improvement
- Business Process Control
- Business Process Transformation
- Business Process Re-engineering

Each came with subtle shades of meaning and recipe depending which corporate initiative or guru you were talking to. The differences were more theoretical than significant. Now, five years later, we hear only the one term used.

That dynamic - widespread proliferation and experimentation followed by stabilisation around one, or a few designs, is common if not universal in the introduction of new technologies. Consider the history of the motor car, the aeroplane, the personal computer, the video cassette tape or the typewriter keyboard. When a new technology, or idea creates a new niche in the system of interactions that is an economy, or when a new demand opens a new opportunity, the response of the market is a radiative bloom of innovation followed by stabilisation around one, or a few, dominant designs (4)

A similar dynamic is found in new industries as in new technologies. New companies enter new markets, either as new entrants or when established players seek to diversify beyond their original sector. The market for Facilities Management services in the UK is currently undergoing just such a bloom with participants competing for share on the basis of traditions in IT, technological services, property and estates management, architecture and interior design, catering and hotel services, engineering, construction, image processing and consultancy. As the market matures a new stability will doubtless emerge (30). In the process new business relationships, and new patterns of relatedness, are emerging to challenge old ideas about what is core and non-core and how such services are purchased (6).

The dynamic is also an old one. The first instance on record occurred 570 million years ago in the so-called Cambrian Explosion when the technology of multi-celled life first expanded into the opportunity space of a sea of edible algae. Life experimented with a range of fundamentally different archetypes before settling down to the score or so of phyla which have survived to this day. The story of the Burgess Shale made famous by Stephen J Gould (17) serves as an example of a pattern since repeated at many scales of biological and cultural evolution.

But to return to fads in general and BPR in particular. The rise of fads in management is well documented (e.g.32), as is the disillusionment of many who practice the latest recipe only to find it does not yield the result they expected. BPR is not unique in this regard but - in seeking an explanation - our normal convention is to ask either *What's wrong with the recipe* or *What's*

missing in the people who tried it, such that it did not work. We add recipes to cure the failure of the last recipe heaping fad upon fad rather like the old lady who swallowed the fly.

What we do not do is look at the rise and fall of a business fad from the perspective of the fad itself, as a replicator bent on blindly infecting as many minds as possible. We do not ask: What is seeking its own replication here? Consider the following thought experiment.

BPR Inc.

We invite you to stand in the meme's perspective. See the world through its eyes. Perhaps it will help to imagine yourself as the CEO of *New Fad plc*. Your shareholders will judge your reward by the number of new minds you 'infect'. This is not dissimilar to running an advertising campaign by the way. Launching and marketing a fad is not unlike launching and managing any other product [except the fad that succeeds promotes itself].

Stage 1. Your 'product' has got to have some sort of relevance out there. Launching a product that the market not only doesn't know they want, but aren't ready for yet, is a recipe for commercial disaster. So is the premature launch of a new idea, business solution or paradigm. Galileo, for example, had this problem with the prevailing paradigms of the day. Just as there was no listening for a heliocentric solar system in the prevailing orthodoxy of medieval Europe so, before about 1990, there was simply no listening - no space in the collective business meaning-scape for Process. When the need emerged many memes competed, as we have seen, to fill it.

Stage 2. You have to find some niche. If your fad is not relevant and useful to someone forget it. Any fad that is going to get talked about and written about - propagated in the world - must, almost by definition, first have to be useful to someone. Those who first label a new management technology are unlikely to talk enthusiastically about what failed.

Stage 3. If you are 'lucky' [and there are a whole lot of questions buried between those quote marks], your fad hits/ creates a rising market. When a lot of essentially similar fads offer much the same thing under a slightly different name [or brand] some will succeed and some will not. It may be pure chance as to which first gets critical mass. Replay the tape of business theory since 1990 and we might be talking about BPT or BPI rather than BPR [just as we might be playing the tape on Betamax or Video 2000 rather than VHS format machines].

Stage 4. Early share is critical because of the process by which a fad replicates. As it succeeds consultants with a living to make, managers with a name to make, business school professors with an image to make, journalists with copy to fill, or just plain seekers after enlightenment start to play. Positive feedback rules. Just as VHS became a more favoured format the more users it had (4) so BPR became the easier language to use the more it was used.

For the really successful fad a whole structure of articles, books, recipes, societies, conferences, internet discussion lists etc. etc. emerges. This structure has a vested interest in the replication of the meme by which it is infected, even if it is not sure what that meme means any more.

Congratulations CEO you did it if you got to this stage. Go directly to the bank and collect your \$200.

But think, while you do what has happened:

Somewhere in the process above a switch occurred. To infect other minds, to acquire believers, reputation becomes more important than performance. Whereas early sales may be on the basis of benefit conferred to a company later sales are on the basis of status conferred to an individual and even current fashion. We have the fad because everybody has it.

Memes remember have no foresight. They exist to go on replicating and preserve the structures and behaviours which enable them so to do. A virus succeeds even if it kills those it infects provided it is transmitted first. Syphilis increases libido [or so we have read]. Re-engineering may drive companies to corporate anorexia (12) in the name of being lean and mean but that is of no concern to the re-engineering meme, provided only that it can go on replicating. Its lack of foresight may ultimately be its downfall. Space is created for a new fashion in articles asking: What's wrong with BPR. New more vigorous fads invade old territory until they, too, keep people equally stuck.

THE LEARNING ORGANISATION MEME

The concept of Learning Organisations emerged into the world of business theory at about the same time, or shortly before the BPR meme. Interestingly it seems to have evolved largely separately several times. Perhaps learning as meme already had its niche in the language of academia. What researcher after all does not like to think that they belong to an institute of learning [and how many university departments that you know would you really classify as learning organisations?].

Perhaps also the learning organisation has had a harder time infecting the listening of the practical business audience because the language [the meme] triggers more defensive routines in the memetic pattern of the practicing manager who has escaped all that stuff. Many a successful manager is after all doing, what observers might choose to call organisational, or action, learning without needing the benefit of the learning organisation meme. They may call it innovation, or performance, or even Process Re-engineering. They may even simply call it managing!!!!

We do not actually know what a Learning Organisation is. We do know that competing definitions abound and that is there is no common sense of meaning conveyed by the term, even within the bounds of this conference. John Harvey -Jones gives a, relatively pragmatic, senior businessman's definition when he refers to the Learning Organisation as *the Philosophers Stone of Business; the thing everyone is searching for that no one he knows has found*. By contrast Thurbin (34) argues it can be reached in 17 days! Some equate the LO with the capability to adapt, react and change in contrast others [especially Senge and those inspired by him] who would rather reserve the LO as something of a vision, a quest, a search for generative innovation and a new sense of community in organisations; one in touch with traditions other than the dominant paradigm of western business.

Another more operational viewpoint sees a LO as one in which ideas and lessons learnt are, openly and quickly adopted elsewhere in the company, or for some pioneers the whole supply chain. Not many companies manage such learning well despite databases of good practice, and

books of lessons learnt. Some professional services firms do it very well and a few companies have cultures where it just happens as a matter of course.

Other schools seek to capture the high ground of learning for a particular function within the corporation, usually the corporate centre hence planning as learning benchmarking as learning audit as learning and even control as learning. Most notably of course this pattern prevails in the HR function where learning often appears as a flag behind which the personnel and training specialists fight for their place in the sun and share of the corporate resource. Consider this definition of the top [sixth] level of maturity of an organisation from a recent article in the UK *is* IPD magazine:

Training and Learning are the process through which strategy is formulated: Are HRD people at the top table as both actors and facilitators in policy formation? Is the organisation acquiring the characteristics of a Learning Company?

Why the right hand state is a prerequisite of the left is not explained.

Yet, albeit gradually, a Learning Company is becoming perceived, even by pragmatic business people as something they want to be. The Learning Organisation is not so much a meme as an opportunity space that many other memes are seeking to occupy. Whereas various, similar, recipes and names competed for market share of Process Management space, different meanings compete for the LO label. The confusion - and righteousness - thus engendered probably hinders any of them becoming dominant.

It also enables much pleasurable discussion and debate into what a Learning Organisation really is: a debate which unfortunately falls frequent victim to the *my meme right your meme wrong syndrome*. We can be so stuck in our unconscious traditions, biases and language, so thrown to a condition of being right that we fail to enquire into what is possible.

SO WHAT IS POSSIBLE?

The science of genetics has revealed the value of genetic diversity as a source of innovation; a richness from which new forms of order can emerge, or indeed can be deliberately sourced. The new science of complex systems is showing that order emerges from a diversity and critical density of inter-relatedness and inter-connectedness (20) (21)

New futures in the human world, new individual perspectives and aspirations, new systems of beliefs and assumptions, new relationships at the inter-personal level, new organisational innovations and inter-organisational relationships likewise emerge from new and different connections between people and ideas. New language, and new listening, can create new futures. Just as genetic diversity is a source of biological wealth so memetic diversity is the source of cultural wealth. It resides in different thinking and is exchanged and grown in different conversation.

Neither memes nor language is unique to the human species. Parrots have their own language as well as the ability to mimic ours. Parallels with human organisations may strike the reader!!

What can differentiate us is our freedom to choose. We do not have, in Dawkins words, to suffer the tyranny of the selfish replicators. We have the capacity, if we choose to exercise it, to see or at least to enquire into the rivulets and lakes of our perceptual landscape and ask how the world around us, and our interaction with it, might change if we choose to operate from a different perspective. When we do we can, perhaps, cease to be victims of our prior experience and conditioning and instead become authors of different futures: futures in which we can enroll others if we create the space for the emergence of a different meaning space; one that offers a rationale, a set of rules, and a relationship for learning.

This is key. We have the latent capacity to be, and perform, differently, individually and collectively

The learning organisation can foster memetic diversity if it creates a context, an environment, where thinking and acting differently in pursuit of different futures is acknowledged and enabled. Creating memetically isolated populations is an easy enabler (26)(29) but the resultant tension requires the balance of a context which encourages exchange of ideas between such populations (see 4 for the fundamental theory). The danger, in many organisations, including those that seek to perpetuate the Learning Organisation is that the debate centres on what the Learning Organisation is. Social and political processes ensue that disenfranchise or excommunicate those who do not conform to the party line. *Different people placed in the same system produce the same result* (2). The result is the slow death of learning. Hence we offer our concluding paradox:

The learning organisation will only be a learning organisation when it is not stuck with discussing what a learning organisation is.

If instead, in any organisation, the conversation concerns what the organisation will be and do, and how people will relate to each other in the doing much more is possible.

POSTSCRIPT

A danger of departing from established conventions of academic papers is that one fails to convey and acknowledge the depth and breadth of contribution derived from the works of other authors. We include here a brief reference to some of the contributions that have had a major influence on the emergence of our own memes. In earlier contributions to the ECLO series (16) (27) and elsewhere (6) (28) (29) we have tried to provide more complete references. Our pending book “Shifting the Patterns” explores all the issues presented here in more detail.

Dennett’s recent book (10) offers a rigorous review of the emergent field of memetics. Our intellectual synthesis would grant more influence to autopoiesis (23) (24), self-organisation (1) (18) (19) (33) (36) and punctuated equilibrium (11) (15) (29). We would assert that memes explain the well documented influence of traditions on behaviour (6) (12) and the link between being, speaking and results (e.g.6). Many of Morgan’s images of organisation (25) can be explained by the same proposition as can the successes and failures of many approaches to the facilitation of change and learning. Ultimately one does not need an explanation of a fundamental process to utilise its effects. You can drive a car without understanding the

workings of the internal combustion engine. You are less likely to be able to tune it for a different level of performance.

Text of an article published in the Critical Linkages Newsletter special issue of September 1997

It was the end of a typical one-day management conference in New York. I happened to be in town and dropped in to post conference cocktails to meet up with a friend who had been speaking. As the crowd thinned I fell into conversation with a guy who, at first sight, looked like another stereotyped, cautious executive but who began to speak with passion and enthusiasm of the new mood that was sweeping the company he worked for [a large food manufacturer]. They had, he said with pride, just completed their ninth record quarter in a row; results driven not by lay-offs but by people thinking and behaving differently.

How? I said, having just spent two years living through what was shaping up to be a similar, though not so painless transformation.

I guess said my companion it started with our new CEO. He is Australian. They are different.

Too right sport said I - giving free rein to a long subdued Sydney drawl. What did he do?

Well I guess it started when he blew up the headquarters.

What? You mean literally.

That's right. Ours was a company proud of our traditions. The Head Office was in the original building designed by..... [*the founder*] when he built the first plant. Bruce [*I've forgotten the man's real name*] had it dynamited. He videoed the occasion and sent everyone in the company a copy. They got the message.

At the time I was working for the world's third largest oil company leading what the CEO had called the Process Review project. Part of our role was to be one of the catalysts for a transformation that he had kicked off two years earlier. Part was to examine what practice and theory existed in other organisations and in the consulting firms and business schools from whom they were drawing inspiration. We were coming to see organisational change and learning as dynamic and individualised process. And we were beginning to find metaphors from biology and geology particularly appropriate to capture the essence of the change process. Perhaps it helped that I was once a geologist.

In a nutshell we had concluded that the process of organic evolution in a dynamic ecosystem provides the paradigm with which to understand organisational adaptation, both in general and in the specific case of our own experience. Contrary to popular misconception evolution is not a

process of gradual steady state change but is instead the organic response to punctuation of a normal equilibrium. Similar dynamics exist in organisations. The process of lasting change, however it is achieved is one of interrupting whatever it is creates and sustains an organisation's equilibrium. Big bangs in the HQ are one way to do it, literally as in the case above, or metaphorically. They are not the only solution for, contrary to the one best recipe schools of both managers and their advisers, there is no one best way. There may however be one basic process.

OUR EXPERIENCE

The big bang in the company I then worked for, BP Exploration, was instigated by a series of management conferences and special projects designed quite specifically to raise the level of creative tension in the organisation and to weaken the influence [as well as reduce the size] of various central functions. After a year of raised tension each operating centre in the company was charged with making, over the ensuing three years, a breakthrough in its operating margin. The details do not matter. Suffice it to say that the figure demanded exceeded reasonable expectations from industry benchmarks and was generally held to be impossible. Every operation achieved it in under two years, each in its own way, with the help of whatever advisers it choose to employ.

Our Process Review team lurked in the background as a stick which might be used by the CEO if he had to but without the formal power to influence how any change was achieved. In the event the stick remained unused, at least where the formal operations of the organisation were concerned. Every local management team discovered its own solutions, each of which involved challenging the patterns of thinking and behaviour that had previously prevailed; its own assumptions about its business.

In this respect the company was like few others that we visited during the course of the project. In the others, in case after case, we saw equivalent head-office groups and their chosen advisors involved in designing and mandating, or facilitating, the process of change. In very few such cases were lasting results achieved even when the change processes gathered a momentum and life of their own.

For a year and a half the process was distinctly uncomfortable for those of us in the team. The lack of formal authority to act within a conventional structure was hard to take for a group whose managerial careers had, until then, been developed within conventional frames of reference concerning authority and conventional political structures to get things done and advance one's own career. Only gradually did we realise that a perceived source of weakness when we started was a source of strength which triggered our own innovations in learning from the experience of business units undergoing change and in discovering means to energise that process. As we did so our paradigms shifted from a primary focus on the formal business process of how things are done to an understanding of the need to integrate business and human dynamics if lasting differences are to be made. An organisation is an amalgam not only of hardware and software [physical resources and operating systems] but also of liveware; people and the thinking processes, belief systems, behavioural codes, and conversational habits that shape their day to day actions.

LIVING COMPANIES?

Since then of course our experience of the failure of many centralised exchange initiatives has been validated many times by research reported in business literature. Yet still the search for the one best way to tune the machine that is the organisation continues. Gradually however, with advances in theory and practice, with insights from the newer business gurus and with progress in applying the emergent science of complex adaptive systems to organisational settings, a new paradigm of organisations is indeed emerging. The world of management is coming to realise that organisations, quite literally, have a life of their own. Like organic species they evolve and adapt, or else go extinct. They exist in networks of interacting entities called economies or ecologies; systems in which individuals occupy particular niches and systems that have, on various time scales, the property of maintaining a quasi-stability for long periods of time between intervening short moments of change.

To the extent that evolution penetrated classical management thinking it was as a metaphor for gradual and even managed change. *Evolution not revolution* is the plea, not least, of managers seeking to control and perhaps limit the pace and impact of change in their particular company. Yet the evidence of geological history is that evolution does not work like that: its tempo, relative to the time available, is stasis or near stasis interspersed with crisis. Evolution is either revolution or it is nothing. The new view of geological evolution is itself only some 20 years old. It started with reappraisals of what geologists call the stratigraphic record, with the evidence from oil exploration wells and particularly with the seismic technology developed in the oil industry since the early 1970s. Without repeating here details that have been amply documented elsewhere suffice it to say that since then we have come to realise that the history of both physical and biological environments on the planet has been, as an early pioneer of the new thinking put *it like the life of a soldier; long periods of boredom and short moments of terror*. Why? And more importantly why [on a different timescale] does organisational evolution show the same dynamic. What is the source of an organization's equilibrium, its stability and even its tendency to seek to preserve that stability even as the world around it changes? For an organic species the answer is its genetic code; information chemically coded in molecules of DNA which effectively specifies the form of a species, enabling it, or more precisely individual organisms within the species to be better survivors than their rivals, but at the same time limiting the individual to be what is specified by the genes; no more and no less. From the gene's eye view of the world this is a suitable state of affairs for the gene is a replicator, interested without conscious forethought in producing copies of itself. The inherent tendency of genes to replicate is the driving force of evolution. To do so they must build survival machines, organic bodies, that will reproduce in a world populated by competing survival machines encoded by rival gene complexes. These complex systems of interacting genes and the bodies they specify seek the stability of an Evolutionary Stable System or ESS; one in which, within the limits of fluctuating populations, a stable genetic mix is preserved. Most variants are swamped in the larger gene pool and bursts of innovation [evolution's moments of change] happen when either the biologic equilibrium is physically punctuated or when small populations evolve in genetically isolated communities. So do organisations have their equivalent of the genetic code?

We believe they do. Examine any organisation and you will find a series of unwritten but widely followed rules of the game; rules that specify sensible behaviour for those who wish to remain in

and prosper in the organisation. You will find mental models or paradigms, codes of behaviour and patterns of values and beliefs that govern who belongs and who does not. You will find particular assumptions and meanings conveyed and created in the nuances of language and jargon that an organisation employs. You will find traditions that are accepted as part of the way things are around here.

My colleagues and I have stopped trying to make precise distinctions between say a belief system, a set of shared values or theories in use, or paradigms or mental models. It is not clear where the unwritten rules of a particular company become its culture or the way things are round here. We prefer to say that every organisation has a pattern or a mix of shared thinking and language which enables it to operate. Until some such shared pattern emerges, whether it is a strategy, sense of business purpose and objectives, a set of religious beliefs, a shared language, or a prevailing set of theories underpinning an academic discipline no organisation exists. There is a chaos of random interactions upon which some would be leaders seek to impose order by force of personality or rewards. The collective pattern defines the organisation. In the language of complexity theory it is the attractor around which the organisation stabilises.

Conventional views have it that we humans create organisations and perhaps that they in turn create patterns but consider the organisation from the pattern's point of view. By enabling, and in effect specifying a certain form of organisation a pattern seeks, again without conscious forethought, its own replication in the world. It works in precisely the same way as the genotype of an individual organism or the genome of an organic species. It is in fact a replicator, enabling the appearance in the world of the survival machine that will ensure its own replication. In the language of biological ideas now finding their way into philosophy, psychology and organisational theory the pattern is the memetic code of the species.

Just as fundamental change in the organic systems, whether designed or evolved, requires a shift in the prevailing genetic codes so we argue in organisational systems a change requires a shift in the prevailing memetic or mental pattern; the collective meaning set that is transmitted by an organisations unwritten rules of behaviour, by its language and indeed by its cultural artefacts. Just as religious buildings, whatever their other functions, help preserve the belief set embodied in a particular religion so a corporate edifice, like the one destroyed in the example with which I started the article, helps preserve the underlying pattern of an organisation. To create a change that pattern must be shifted, whether by design or accident. Those who design change programmes that do not shift an existing pattern should not be surprised when the pattern strikes back; for when the chips are down the pattern is not there for the good of the organisation. It is, like The Selfish Gene, there for itself. It operates on the minds of people who carry it to ensure its own survival, as surely as a flu virus operates on their bodies, inducing behaviours selected to enhance a replicator's chances of replicating. Change the pattern, either by changing the context in which it operates [dynamite can do the trick¹] or by changing the conversation and rules by which it is transmitted and you change the organisation.

SOURCES AND ACKNOWLEDGMENTS

In reaching the theories put forward here my colleagues and I have drawn upon emerging ideas from many fields of practice and theory. With a colleague Ray Shaw co-author of a forthcoming

book “*Shifting the Patterns: Transforming the codes of personal and organisational performance.*” I try to explore these ideas in more detail and acknowledge the many sources from whom we have drawn inspiration.

Readers wishing an academic summary may find it helpful to refer to my paper *Organisational Memetics: Organisational Learning as a Selection Process*: Management Learning 1995 Vol 26/3 pp299-318. A less academic approach, with updated references is Price. I and Shaw R. *Parrots Patterns and Performance: Emergence of a New Management Replicator* delivered in May 1996 to the annual meeting of ECLO; [The European Consortium for the Learning Organisation] and available from them, and over the www from September this year.

During the Process Review experience I had the unique opportunity of working with Peter Scott-Morgan whose approach to analysing The Unwritten Rules of the Game, was subsequently published by McGraw Hill in 1994. Shifting those rules remains for me one of the essences of pattern shifting.

Ifryn [If] Price is a consultant/ educator/ researcher and writer/speaker on exchange. He originally trained and worked as a geologist in many parts of the world. Before creating the Process Review Team described here he was manager of BP's world-wide Exploration and Production Research Division. In April 1993 he left corporate life to co-found The Harrow Partnership Limited; a group devoted to helping people and organisations release the potential trapped in their limiting patterns. If is also a Visiting Fellow of Sheffield Hallam University where he teaches benchmarking and organisation transformation and facilitates several organisational learning forums. With his partner Hazel he also directs Active Personal Learning a company dedicated to helping individuals and smaller business grow through the use of accrediting acquired competencies.

THE AUTHORS' REPLY TO PAUL MARSDEN'S BOOK REVIEW: MEMETICS AND THE EDGE OF CHAOS

By

If Price and Ray Shaw

Facilities Management Graduate Centre, Sheffield Hallam University
and The Extraordinary Performance Company Ltd, Reigate.

I.Price@shu.ac.uk RayShaw1@compuserve.com

In reviewing *Shifting the Patterns* (STP) Marsden identifies us as taking memetics to the edge of chaos; a comment we welcome if only because our intellectual underpinning for the book draws on that other emergent science - complexity - as much as it does on memetics and standard neo-Darwinian evolution. Unlike say Dennett (1995) who sees in complexity and Kauffman's (1993) ideas a search for a skyhook, we see complexity and a general science of selfish replicators as necessary complements to one another in the search for the understanding of the origin and self-maintenance of complex order (Price, forthcoming). Complexity offers the 'edge of chaos', as the setting for the emergence of new order and we make no apology for also offering it as the metaphor for the release of individual and organisational possibility.

Marsden is quite correct that we attempt to use what he has aptly termed "*the memetic stance*" (Marsden, 1998) to prompt solutions to real-world issues rather than write a book on memetics. STP emerged as our manifesto for the release of human potential. Its conception involved the dilemma of our desire to both produce new scholastic ideas and yet to write outside the standard patterns of 'management books'; patterns which tend to lump the market into the categories of 'scholastic' or 'how-to'. The memetic stance seems to us to be indeed an "*ontologically minimalist heuristic*" (ibid.); one capable of unifying a wealth of broadly evolutionary explanations of human phenomena at all scales from the individual to the 'inter-organisational'. Though we wrote mainly in the context of companies we see the message as pertaining to all forms of organisation and are delighted that, within a month of STP reaching the world we had favourable feedback from readers concerned with such patterns as their marriages, drug addiction and better support for children at risk as well as from a more conventional management audience.

However when Marsden argues that "*rather than take the conventional view that individuals are the hosts for memes which are transmitted through individual behaviour, STP argues that companies should be understood as the proper hosts to memes*" we must take issue and urge a more inclusive perspective. It seems to us questionable to label that the conventional view (see for example Hull 1988, Lloyd 1990) but more importantly we would argue that forms of 'company' more complex than an individual are an emergent property of shared memes, transmitted through language and cultural artefacts. They do then indeed become vehicles for the replication of those memes.

Marsden goes on to cite the problems of our:

"Unorthodox understanding of the relationship between meme and organisation ... particularly with respect to the organism/company (dis)analogy. Organisations are not physically bonded,

rather relations between their constituent parts are informational and not physical and thus not confined to predetermined paths. Organisations themselves do not reproduce whereas organisms do. Thirdly unlike organisms, organisations have phylogenies. Fourthly, and perhaps most critically, companies do not have any needs themselves, unlike individuals, so it is difficult to see how evolution can operate at the level of the organisation."

To deal, briefly, with each point, first extended phenotypes (Dawkins, 1982) are not physically bonded neither are, say, symbiotic organisms co-evolving, yet replicator theory explains the resultant complex order. Second organisations, or at least organisational strategies and processes, are very definitely reproduced through imitation (Lloyd, 1990). Third McCarthy et. al. (1997) have demonstrated organisational phylogeny and introduced the prospect of the twin sciences of organisational memetics (Price, 1994; 1995) and organisational cladistics. Finally, while companies may start as vehicles to deliver individual needs we would argue they become institutions with, in a sense at least, their own - or their memes' - needs. Who in an organisation has not heard the expression 'what this organisation needs is

We are then accused of exacerbating problems in the partial gene/meme analogy by conflating 'pattern' and 'meme'. True perhaps but we in good company. Dawkins (1976) makes very clear his use of 'The Selfish Gene' as a metaphor for the interaction of several poorly defined bits of a chromosome interacting in complex chromosome system. We tried to make the same point clear (p159/160). The science of genetics has had a century's start on memetics and manages to embrace both generalist and specific concepts of gene. We would agree the need for a memetics to evolve its own specialist terminology but suggest the generalist conflation of meme, like gene, benefits the wider appreciation of the memetic stance. Research memeticists will undoubtedly evolve their own special memes if only because replicators abhor a vacuum in replication space. The process will, inevitably, be a selection process between variants on the meme of meme and its derivatives. We may for example find ourselves requiring at least two distinct meanings of 'host', at the level of mind and of organisation. But then where is the host of the gene? Is it the species, the body, the cell, the nucleus?

We also admit to freely switching between gene and virus analogies (we challenge their looseness). 'Double-helix' replicator theory suffers a similar confusion. DNA (gene) based organisms are also hosts to RNA based viruses. If memetics is restricted to the viral level then science needs another word for the wider organisational replicator. The alternative is to keep 'meme' general and derive more specific terminology where it is needed. "*Confusion over the unit and level of evolution*" is not unique to memetics. "*It is not at all clear whether rules evolve, organisations evolve or more amorphously, patterns (of rules behaviours and organisations evolve).*" Memes, we argue, evolve through the emergent web of institutional rules, language and artefacts that they enable.

Marsden continues:

"If memes are taken to be socially acquired cultural instructions then the cogency of STP largely holds together, and the framework presented is somewhat similar to Cloak's cultural ethology of i-culture and m-culture (Cloak 1975). Indeed the authors might have usefully exploited the clarity of this framework, but instead no reference is made to Cloak. On the other hand, by

adopting Dawkins' meme concept uncritically, the authors also add the ambiguity inherent in Dawkins various conceptualisations (see Gatherer 1998) to their own framework."

We agree and were, at the time of writing unaware of Cloak's distinctions. At the level of scientific objectivity those distinctions are indeed important. In STP we were more concerned with utility and the 'tyranny of selfish replicators'.

We were likewise unaware, at the time of writing of "*Allison's (1992, 1993) work on the spread of non utility-maximising rules through populations* or Burns and Dietz's institution theory (1992a, 1992b, 1996, 1997a, 1997b). We are pleased to agree their relevance and welcome yet another body of organisational observation amenable to the memetic stance or the selfish meme heuristic.

We do though see the 'long periods of stability - short moments of terror' (Ager 1973) dynamic of the evolution of the complex geological system on which we all live as a fundamental property of replicator driven systems, a conclusion we sought to substantiate by reference to observations at various scales of existence from the geological to the corporate (see also Price and Kennie, 1997). "*Reports of the death of gradualism have been greatly exaggerated, and Gould is*" - indeed - "*not the only evolutionist around*". Unfortunately some of the others seem to us so preoccupied with how evolution ought to operate that they are less concerned with the evidence of how it has operated (patterns / memes again!). The geological - biological debate over places at the high table of evolution may yet mirror itself in memetics.

Then we reach "*the most controversial aspect of STP for memeticists is the idea that the self, and importantly consciousness, are not memetic, and that a non-memetic independent freewill somehow allows individuals in organisations to act with true intentionality. In other words, the dualist homunculus is left untouched by the authors' conceptualisation of memetics*". We stayed out of that one because of concern for utility rather than 'truth'. Too far down that line of reasoning, even if it is neurophysiologically 'true' lies the danger of abrogation of personal or social moral and ethical responsibility. We do not however see a need for a dualist homunculus to evoke a mind capable of inquiring into its own existence and own choices. There is a fully self contained explanation. Memetic patterns which permit an inquiry into other memetic patterns residing in the same brain, grant themselves a certain trick in replication space. Some memes have always granted the minds that carried them some power of inquiry into underlying assumptions. Sometimes they got their host excommunicated / burnt at the stake / made redundant or otherwise disposed of but they nonetheless replicated and also, on balance, enabled the progress of cultural evolution. The memes of inquiry live on because they also enable their hosts (at all levels of organisation) to achieve greater results and are an antidote to other, more parasitic, memes. We see much power in Blackmore's (1996) conception of meme-eating memes. In deploying them, people can at least influence the evolution of companies, through both selective transmission and also the creation of new memes derived from a new understanding of the patterns that code for performance. While the school of meme theory, "*concerned with deconstructing pervasive homuncularism understanding human behaviour*" has undoubtedly brought new insights and explanations of human behaviour we would return to Dawkins' original conception of the meme as an example of the power of replicators to enable and maintain complex order. We hold therefore that there is a science of organisational memetics; one that has the potential to finally provide an explanation for the existence of

organisations, by recasting in one simple heuristic numerous other observational stances and perhaps even one capable of giving people the dualist homunculus that they have not previously had. Now there's a thought!

STEPS TOWARD THE MEMETIC SELF

A commentary on Rose's paper: Controversies in Meme Theory

By
If Price

Facilities Management Graduate Centre
Sheffield Hallam University
I.Price@shu.ac.uk

1 Introduction

As the editor of JoM-EMIT points out, some authors in memetics have suggested (explicitly or implicitly) that 'consciousness' or a 'Self' beyond the constructs of memes and genes can choose or design memes (most famously Dawkins' (1976) call to 'overthrow the tyranny' of the replicators). The alternative position eloquently argued by Rose holds that attributing variation and selection of memes to some form of conscious self beyond the reach of the meme "*not only undermines the value of meme theory as an evolutionary process, but is also a kind of giving up. If we intentionally design and choose memes 'why do we need an evolutionary theory of culture at all?'*".

This essay is written as an invited contribution to the debate, one I am glad to make if only because Ray Shaw and I (1998) have written what one reviewer (Marsden, 1998b) termed a 'manifesto for a velvet revolution' against the tyranny of selfish replicators and dropped easily into the language of individual, goal-directed, choice without addressing the question of whether such a self is, in point of scientific fact, a logical impossibility. Here I may redress the balance. The effort comes in three sections. First I seek to clarify the meaning of meme being used. I then ask whether it is necessary to invoke some conscious self beyond memes, some residual dualist homunculus, if individuals, and groups, are to free themselves of the tyranny of the selfish replicators. In these two sections I will seek to hold to the conventional scientific interpretation of truth. Are we arriving at a better explanation for the working of the natural world and human social systems within that world? In the third section, and the third section only I will address the limits of that particular meme of truth.

2 What meme of meme?

Price and Shaw (1996) used memes drawn from organisational theory and practice to seek an illustration of what may be a typical life cycle of memes in other spheres. To create some replication niche for themselves memes, when they first evolve, must enable some form of result, confer some benefit for those who are their first host. Whether this is a universal need may be open to debate but enabling is a useful strategy for replicating. At some point however 'successful' memes, where success is judged purely in terms of replication, need not confer any benefit, provided only that they spread. Business fads provide numerous examples.

From the meme's perspective it is not necessary that replication has a high fidelity. Many business fads (and other memes) become labels whose carriers try and attach different meanings to them. The 'meme' meme is undoubtedly currently enjoying a considerable radiation, one accompanied by a wide, and growing, divergence of meanings attached to it (Edmonds, 1998).

Such divergence is probably another inherent facet of memetic replication. Compared to genes, memes have traded replicative fidelity for replicative speed. From the selfish meme's perspective, so what? Success, for the 'meme' meme is purely the number of individual human minds who now store some form of meaning associated with the word 'meme'. If it causes confusion then so be it. At least the 'meme' meme is replicated.

The diversity of meaning does though limit carriers of the 'meme' meme when they try to inquire into the power of memes and the limits, or otherwise, of memetics as a theory of either the individual mind or of various forms of social organisation involving more than one mind as members. Rose (op. cit.) is again lucid on the confusion which has arisen from Dawkins' original use of cultural artefacts, Cloak's (1975) 'm-culture'; rather than the cultural instructions inside the brain which produced these artefacts Cloak's i-culture to exemplify memes. In trying to arrive at a theory of organisational memetics (Price 1995) I have taken the same interpretation as Rose and conceived of memes as ideas or information, in essence the i-culture. Memes, under this interpretation, may be replicated not only via cultural artefacts but also through language (c.f. Cavalli-sforza and Feldman, 1994) and through the implicit unwritten rules found in any form of social organisation. My own memes in this area derive from Hull's (1988) interpretation of the unwritten rules of the scientific process as vehicles for maintaining particular paradigms and Scott-Morgan's (1994) work on unwritten rules.

The confusion should not be allowed to detract from Dawkins' original point, the power of replicators to enable the emergence, and maintenance over time, of forms of order which are out of thermodynamic equilibrium with their environment. Darwin's 'Dangerous Idea' (Dennett 1995) seems to offer not only the one truly sustainable 'scientific' explanation we possess for the why the biosphere is the biosphere but also the potential for an equivalent explanation of all forms of organisation. The combination of memetics and complexity (Gabora, 1997; Price, 1995; 1999) offers rich potential as we examine not individual memes passed on through imitation, but rich and densely interconnected memetic patterns. An ironical property of complex adaptive systems (CAS) is their tendency to seek to maintain evolutionary stable states. We need to consider, as forms of memetic phenotype, not just individual 'viruses of the mind' but also all forms of social organisation (social CAS). Any individual mind is a product not only of particular individual memes but also of the wider social memes too which it has been exposed. Hence for example I view my mind as carrying a memetic pattern imprinted (among other things) by the English language and tradition (with overtones of the Australian sub-species), by early training as a geologist, and by a career spent within managed commercial organisations. One individual mind can be a member of many different memetic organisations. Can that mind also have any form of free-will, any ability to choose between the various memetic strains that have made it what it is?

3 The memetic self

A more generalised theory of replicators applied to the complex system that is the human brain / mind would hold any one brain / mind combination to be the product of some mix of our genetic and memetic inheritance. Where the boundary is crossed, if indeed it is, is yet another of the unanswered questions of memetics. As I understand it one school of cognitive evolutionary psychology (e.g. Pinker 1997) seeks to argue a genetically specified capability for perception,

image coding, memory, language and information processing as capable of yielding a conscious mind without recourse to memes. I prefer Dennett's view of a genetically coded brain converted to a mind when it becomes the resting place for memes. Price and Shaw (1998) *exapted* a De Bono metaphor in the image of a landscape, eroded over time to provide streams, rivulets, and rivers interspersed between higher plateau as a simple example of a self-organising, locked-in, system. As rain falls on a virgin landscape so it tends to find the paths of least resistance: the soft rocks and minor depressions of the undulating territory. Over time accumulations of rainfall carve out stream and river beds and settle into pools and lakes. Any new rainfall will no longer find its own way but will rather take, and reinforce, the routes which already exist.

Just as the rainfall follows established routes, so perception follows established ways of *seeing*. Technically, even if the light sources which perturb the back of the retina are identical, what will be noticed from all that could be seen, will depend on the perceptual lens through which someone views the world. The optimist's half-full glass is the pessimist's half-empty one! What is 'there' is not independent of the viewer. What is there is what we have been *trained* (or conditioned or have learnt) to see. Our training in terms of our mental models means that we will not see certain other things which do not fit with the memes we carry. We may discard, indeed we can be blind to, anomalies that do not fit. The self-organised pattern which we call our thinking grants a particular perceptual blindness and rigidity to our perceptions of the world - the very foundation of such things as stereotypes and prejudices - common to all human experience and found, for example in the way one department in a company may view another.

What holds for light waves perturbing the retina, holds equally for acoustic perturbances of the eardrum. Exploring the analogy further we could say that an idea, a single thought, an utterance, a meme in fact, is like the single raindrop. It falls with others upon a pre-formed perceptual landscape. Isolated thoughts gather together in a string - a pattern of co-existing memes - which we might compare to a few drops congregating together in a splash of water. With sufficient mass the splash of water starts to flow into streams and rivers which are, if we like, the connectors between the raindrops and the pools and lakes, if not the oceans, of our thoughts. The pools and lakes we may view as concept pools and theory lakes. Thus a self-organising system is inherited and developed in which the flow of perception takes a certain course; it follows a certain pattern, a largely given paradigm.

Patterns in the brain influence *seeing* (or more accurately perceiving). Patterns, and seeing influence behaviour so that behaviour follows certain patterns. It may be argued that we see the world less as it is and more as we are, and that we act perfectly consistent with how we see the world. There is a certain alignment with our thinking, our perceptions and our actions-in-the-world. Thinking, seeing, and behaving tend to follow pre-existing patterns.

Yet that pattern carries some ability to inquire into, and make sense of, the environment around it. An inquisitive ability, albeit a limited one, seems to be one of the evolutionary tricks of our species biological endowment. Genetic selection hit (for reasons which may be fortuitous - e.g. see Morgan 1997) on a combination of a large brain, an enhanced vocal capacity, an opposed thumb and an upright posture. Whether the experiment would have succeeded if it had not provided the environment for accelerated, memetic, evolution is a moot point. Our hominid ancestors had to live in a world where many faster and physically stronger predators must have

regarded them as an alternative lunch. Tool making, communication, and a faster rate of learning from each other and their environment proved advantageous evolutionary adaptations. Equally a tendency to accept, without question, the mores, beliefs and behaviours which granted any individual membership of a particular tribe, or other social group conveyed a different form of selective advantage. There was safety in numbers. One's own replicators were less likely to end up as some other replicators' lunch.

The inquiring (within limits) mind and the socially acquiescing (within limits) mind is thus perfectly explicable as a natural evolutionary development; a product of Darwinian selection. That mind enabled the species which carried it to outgrow the limits of their genetic inheritance, and periodically to challenge the limits of their memetic inheritance. Such challenges did not always come easily. The history of the development of ideas is replete with examples of the painful ends which awaited those who challenged prevailing epistemological orthodoxies. While Dawkins phraseology, 'escaping the tyranny of the selfish replicators' may be accused of a certain literary excess (a useful memetic trick) it is not necessary to invoke a self out with the meme-gene combination to explain self-awareness or questioning of a particular status quo. It may not even be the combination! An intriguing possibility is that curiosity, the inquiring brain, is an inherent part of our genetic inheritance whilst conformity is memetically induced. It is probably memes more than genes that limit our ability to question a prevailing reality.

Memes for common technologies, common languages and common belief systems sustained and enabled various forms of social organisation from, say, early foraging / hunting groups to any of the world's major nations or religions. If one takes this memetic stance to social organisation it becomes logically difficult to interpret history as other than the record of memetic evolution; an observation which, in turn, offers a perspective of the extent of the tyranny of the selfish replicators. Hobbes' famous characterisation of the life of man as "solitary, poor, nasty, brutish and short" reflects the fate of most members of the memetic species, living subsistence existences with any surplus devoted to the perpetuation of the prevailing memes and the power / caste structure which carried them. In the process most members of the human species became, in large measure, victims of the meme set they found themselves members of. Too great a challenge to an existing status quo has always carried the risk of retaliation by the 'powers that be', that is the agents of the 'memes that be'. The inquiring mind risked the loss of anything from membership of a particular group to life.

Memetics seems to me to offer the prospect of an explanation of the inherent danger of runaway ideological tyrannies, and in and of itself it is thus an antidote to them. Science is itself a memetic selection process (Hull, 1988), and one not free of its own tendency to seek the largest share it can of available resources for its own replication. It is certainly subject to parasitism by malignant and socially repulsive memes like eugenics. It has though enabled a position where we have, in a way that none of our ancestors did, a more accurate understanding of the world around us and our place in it. Perhaps it is only through the memes / genes for the inquiring mind and an appreciation of the power of selfish replicators that we may at last escape at least some of the tyranny.

4 Beyond the science meme

I have tried to write, in the previous two sections, from a perspective of scientific truth. I am inculcated by the science meme and would normally defend the utility of that meme in the pursuit of that form of truth, at least in most contexts.

Switch the context though and even the memes of scientific truth can become limiting. The unchallenged assumption that there must be a single 'truth' or 'right way' becomes a means of defending a particular world view or of creating a particular, self-fulfilling, reality. Assertions with the generic format of declaring something to be true can hold those who make them stuck in a certain reality, parasitised by a certain mind set, victims of a particular memetic pattern. The phenomenon works at scales from the individual to the societal. More can sometimes be gained by asking not 'is a particular perspective true', but 'is that perspective valid', and 'are there alternatives which would enable me to achieve a different result?' To a believer in memes it is difficult to see any particular religion for example as true, yet one can perhaps see many religions as valid, if only because, by providing a rationale for desirable codes of social behaviour they enable certain common value systems. Achieving even a semblance of commonly accepted ethical standards may be harder in a world without religion. This is not to say that there are not many circumstances in which religions limit the minds of those infected by them, but merely to allow an inquiry into the possibility of contexts, in which religion might enable, not limit.

The assertion of truth contains also a dark side. An ever present danger in the logic of saying we are all creatures of our memes is the denial of individual responsibility for ones actions, so any action, or even 'any action not strictly prohibited' one individual takes to exploit others is excused. Whether greed and ownership are memetic or genetic is a moot point but truth can be harnessed in the service of the unbridled growth of either.

Because memes may be scientifically true - as the explanation for the complex system that is the human mind - it does not seem, to me at least, to deny that mind the property of inquiring into itself. Indeed, finally abandoning any self outside memes and genes seems to demand more, not less, self awareness. The memetic self either abrogates responsibility for its behaviour 'It wasn't me - I'm just a vehicle' or accepts that the last chance to escape responsibility for ones actions in the world has past. Memetics meets morality.

Notes

1. It is not strictly relevant to the discussion but it may be that this process should be modelled in terms of 'hitchhiker' memes - different subsets of meaning that try and get a free ride in replication space by attaching themselves to an existing terminology. Our 1996 paper used the example of the 'Learning Organisation'.

RECONSTRUCTION OF ORGANIZATIONAL PHYLOGENY FROM MEMETIC SIMILARITY ANALYSIS: PROOF OF FEASIBILITY

By

If Price and Andrew Lord

Facilities Management Graduate Centre,
Sheffield Hallam University, Unit 7 Science Park, Sheffield, S1 1WB, UK.

Abstract

A successful phylogenetic reconstruction of the known pattern of descent of the main post-reformation Christian Churches has been achieved from a computerised analysis of aspects of their present day memetic pattern. The result confirms the feasibility of a new approach to organisational memetics and conducts a first empirical test of the hypothesis that, if organisations are construed as evolving, those with a common ancestor should show greater replicator similarity than more distant relatives.

1 Introduction

Memetics has debated at length the internalist versus externalist positions and the question of whether the individual or organisation should be considered as the memetic 'phenotype'. We approach the topic from an organisational stance (c.f. Price, 1995; Gell-Mann, 1996, Price and Shaw, 1998; Williams, 2000). In brief the stance holds that organisations evolve (Aldrich, 1999) and are constructed or enabled by shared patterns (Schien, 1985; Price and Shaw, 1998), paradigms (Hull, 1988) or schemata (Gell-Mann, 1996). Whether conceived as pattern, paradigm or schemata the proposition would be that they are replicated in the organisations concerned. As noted by Marsden (2000), the stance could be argued to recapitulate an older evolutionary tradition in social sciences, and indeed economics, however the organisational replicator, whatever it is, can be termed meme by reason of the specific origin of the term in the context of a general theory of complex organisation enabled by replicators.

Wilkins recently reminded the memetics discussion list of his earlier (Wilkins, 1998) suggestion that evolutionary cladograms provide a potential means of contrasting the memetic codes of related organisations [note1]:

One such technique that could be used is the Wagner Similarity method (cf *Wiley and others 1991*). This method establishes an instance matrix of characters (presence and absence, but it could be any value $0 < x < 1$) and calculates the sum of the modulus of differences to give the Wagner distance between taxa (or theories). From this a net diagram of relationships, or an unrooted tree, can be drawn up to give a sharp notion of the overall similarity of taxa or theories. The same data can be recast as a rooted cladogram if a sister-group can be selected. Software, both commercial and public domain, is available to perform these analyses and others using well-established algorithms. While this will not definitively establish ancestry of a conceptual lineage, it can be used to test hypotheses of ancestry, and to overcome the Whiggish tendency of

historians to read preferred modern views back into a historical subject, such as Darwin's reliance or not on now-discredited views such as embryological recapitulation.

This research note [note 2] is written to report what we believe to be the first successful explicit test of such an approach. Rather than a Wagner similarity we have used Hamming distance [note 3] (a metric of digital error) and the UPGMA (Unweighted Pair Group Method with Arithmetic Mean) clustering strategy (Sneath & Sokal, 1973; Lapointe and Legendre, 1994) on putative meme strips [note 4] rendered as binary data; i.e. a 'taxon' has or does not have a particular character. We have previously explained (Price and Lord, 2000) the principle behind the method, an examination of further isomorphism between biotic and abiotic complex systems, the reasons for the choice of a test group; and the evidence of an early instance of a successful iteration between inferred and historical pattern of descent and an analysis of memetic similarity. In brief, religious bodies, particularly post-reformation Christian Groups were selected as a test population because they displayed:

- Wide ranging diversity within the group
- Distinguishable characteristics
- Prominent belief systems
- Sufficient historical records
- Periodic evolutionary blooms [note 5]

Comparison with biological evolution leads to the hypothesis that a phyllogram constructed from an analysis of memetic similarity should reconstruct the known pattern of historical descent. The attempt raises issues of terminology. Hull (1988) has used the schism in systematics between cladistics and phenetics as almost his type example of science as a process of selection between competing paradigms (or meme complexes) each of which replicates via the forms of organisation which it enables. Organisational memetics is arguably no more than a generalisation of Hull's proposition (e.g. Price, 1995; Price and Shaw, 1998). Cladists have criticised pheneticists as lacking objective rigour or the logic of seeking to unravel a pattern of evolutionary descent. Some at least acknowledge that the advent of molecular phenetics has, at best, blurred the distinction and at least lead to a resurgence in phenetics. Here we are borrowing from systematics but seeking to test memetics rather than reconstruct descent.

In strict terms we are attempting a phenetic analysis of memetic data however, as with molecular phenetics, we are suggesting that the phyllogram will reveal a history of descent: i.e. will produce the same output as a cladogram. In the domain under investigation the true history of descent is, within certain bounds (see below), established. The objective is not to classify with a view to unraveling history, it is to test the proposition that the organisations examined might be memetically encoded by comparing what is in effect an inferred cladogram (albeit one derived from phenetic methods) with one known from historical sources. The test, if successful, provides evidence compatible with the inferred presence of a cultural replicator in evolving organisations. If memetics becomes (as we believe it should [note 6]) to studies of evolution in the social sciences broadly what genetics has become to studies of biological evolution, then it may develop its own language and terminology. To those whose perspective on evolution is more geological than biological the selection competition between phenetics and cladistics seems to generate more heat than light. The distinctions may prove unnecessary, or even unhelpful for memetics. Such debates lie in the future. Our concern is to see whether a particular analytical

approach is doable, and if so, does it hold out a promise of utility in the field of organisational memetics.

2 Method

2.1 Data

The meme strip shown in Table 1 (appended) was gathered from Internet and other written sources [note 7]. We will leave to others the behaviouralist versus internalist debate and see Table 1 as a list of beliefs and practices that between them characterise and underpin different Christian Sects: beliefs and practices that seem to be replicated in the minds of adherents to a particular denomination and that, in being replicated sustain that denomination. We have applied them to the taxa set [note 8] listed in Table 2 (appended), and, where possible, to individual sub-sects, though here the differences became hard to distinguish. The historical derivation of these branches is illustrated in Figure 1. Taxa in lighter colours are not subsequently analysed. They represent schisms within particular religions, for example a variety of sub groups of Jehovah's witnesses, where we have not yet been able to confirm apparently minor differences in belief and practice [note 9].

Figure 1: Historically derived phylogeny

2.2 Software

A software routine [note 10] has been written to analyse the progressive pairwise similarity of strips of binary data using, as noted above, the UPGMA on Hamming distances. The taxa character matrix is searched for pairs with the least distance between them. The average of such a pair then becomes a new 'parent taxa' which is subjected to future iterations. Fuller details of the validation will again be described in a longer paper but in brief it successfully reconstructs hypothetical, randomly generated data sets, and also, somewhat to our surprise approximates a biological phylogenetic tree from a set of claimed therapeutic properties of essential oils (Lawless, 1992) [note 11].

2.3 Results

Initial results of the tests on our hypothetical religious clades [note 12] (Figure 2) were encouraging, in that clusters of obvious common origin were revealed. However higher order relationships failed to reconstruct accurately: the derived tree did not match the one drawn from historical sources. In particular clusters of Calvinist denominations showed greater dissimilarity between themselves than one such cluster did to major Episcopalian branches. This gave rise to the suspicion that 'some memes may be more powerful than others'; i.e. that the presence of a certain meme in a particular denomination or group of denominations might inhibit its further splitting [note 13]. In particular the non-episcopalian denominations showed greater variety than the did the episcopalian. In essence the 'Episcopalian meme' and the resulting presence of a hierarchical bishopric arguably restricted the possibility of further evolution.

The initial test had given the presence of such authority the same weight (one unit of a binary string) as any other characteristic; a feature, which it was hypothesised, might undervalue the power of an established hierarchy as an antidote to too much change. In order to further test this hypothesis the reconstruction was then tested by assigning greater weight to the bishop meme. Weighting was simulated by inserting extra bishops into the meme strip [note 14]. In successive tests the switch from 7 to 8 bishops produced a tree sufficiently comparable to known patterns of historical descent (Figure 3) to claim a largely successful reconstruction. The switch is illustrated in Figure 4.

3 Discussion

Figure 3 also reveals interesting questions for further analysis. The ancestral Roman Catholic Church does reconstruct as the isolated clade, without significant further splitting: a feature, which would suggest the meme of the apostolic succession to have even greater influence than the bishop meme. Remove one and some evolution is possible; remove two and a much greater radiation occurs. The Lutheran and Anglo-Catholic (i.e.: Church of England) clades reconstruct in the most plausible phylogenic scenario, as co-descendants from some common ancestor. A conventional historical description would treat this as inaccurate. After all Henry VII founded the Church of England in a separate historical event and saw himself as Defender of the Faith against the Lutheran schism. In ideological terms however one could say that post Luther there were two clades, a Roman Catholic one and an unincorporated non Roman Catholic one, which subsequently precipitated and evolved separate branches. The issue mirrors the taxonomic debate

as to whether one biological species can evolve from another or whether two evolve from a common ancestor.

Figure 2: Phenogram derived from character states when the "Episcopal" meme weighs 1

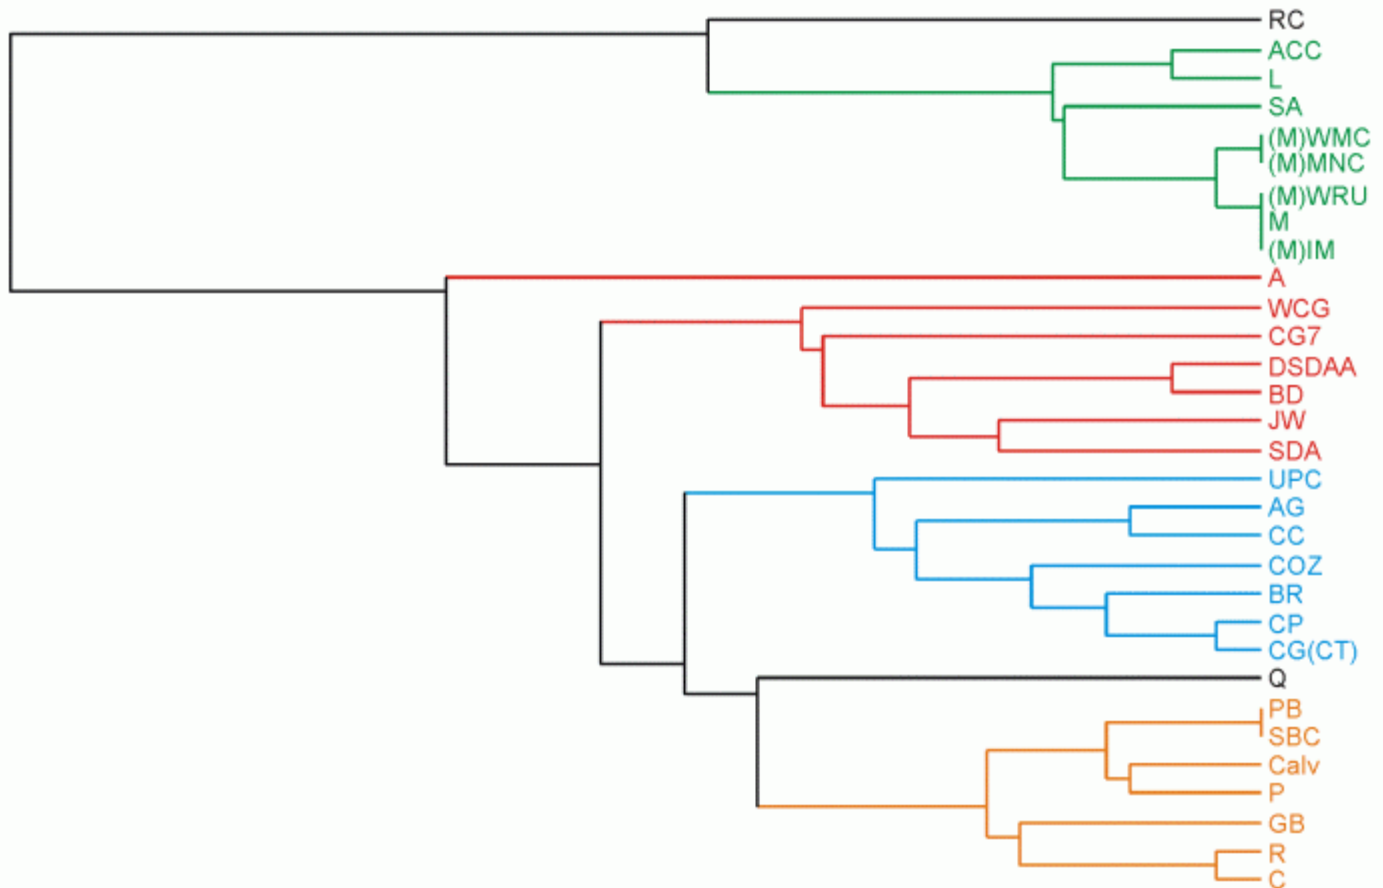

Figure 3. Phenogram with the "Episcopalians" meme given a weighting of 8

There are two significant errors in Figure 3, The Salvation Army and the Quakers. Neither is necessarily surprising. The Salvation Army have replaced an Episcopalian polity with one modelled on a quasi-military structure and the unique implications remain to be investigated. Having confirmed the need to weight power structures in one form of hierarchy it is not unreasonable to suspect its influence in another. The Quakers are in some respects the complete opposite in having gone further than any other 'church' to question authority of position and indeed to blur the boundary between religion and ontology. Both the failures of the reconstruction can then be considered to be exceptions. The approach is demonstrated to be worth further investigation and the results are consistent with a view of organisations as evolving entities with recognisable patterns or memes at their core. The Episcopalian clades in particular are interpretable as organisations devoted to replicating of the 'bishop' meme. There are wider issues raised for understanding the history of Christianity however discussing them takes us beyond the scope of what is possible in a note of this kind. There are likewise issues for methods and terminology of operational research into memetics. Both merit further debate and consideration. At this stage our concern is to demonstrate that the hypothetical approach suggested by Wilkins can apparently be operationalized in practice. A more comprehensive paper will be submitted in due course. Testing of the software variants for other applications continues [note 15]. Meanwhile the evidence that a cladogram derived from a memetic code can

successfully reconstruct patterns of descent seems encouraging news for the emerging science of organisational memetics and a tool with considerable potential in evolutionary analyses of social organisations.

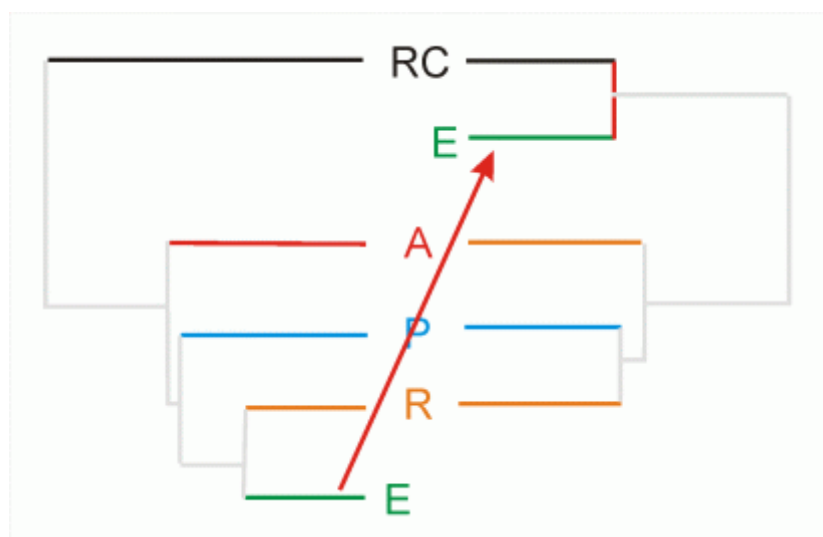

Figure 4: The effect of the changing reconstruction of the phenogram when the Episcopal meme is replicated 8 times in the character string (NB not a computer generated diagram)

Notes

Our conception would see the 'pattern' (sensu Price and Shaw, 1998) or 'memplex' of an organisation as an interconnected system of individual memes, much as Dawkins uses, and is clear about his use (1989 p. 271), the metaphor of the selfish gene as shorthand for a complicated system of interconnected and interdependent genes.

We emphasise that this contribution is intended as a note for rapid publication. A much fuller description of both the method and the data set will be submitted in due course.

And we acknowledge an anonymous reviewers pointing out that one is in fact derived from the other.

We cannot claim that the character set assembled for a given denomination necessarily represents a full memplex. We are listing a series of characteristics postulated to be parts of that memplex and informally describing them as meme strips.

The fossil record, and modern ecosystems, reveals periods of evolutionary radiation as new niches open up, The Burgess Shale and the Galapagos finches are well known examples. We expected tracking of postulated memetic divergence would be easier through equivalent events such as the religious diversity developed by European settlers in North America.

The existence of other evolutionary traditions in social science and other aspirations of scholars in the emerging field is acknowledged. The approach we take remains valid whether or not the replicators are considered as memes.

The primary source, where available, is the home page of the denomination concerned. We have also sought pages classifying and comparing religions and standard reference works. A fully annotated and hyperlinked character matrix of our 'taxa' is in preparation and will be submitted for comparative analysis as soon as the necessary referencing can be completed. Scholars interested in evaluating our results are welcome meanwhile to contact the authors.

A reviewer has commented on the potential bias towards 'sects', particularly of the millennialist variety, at the expense of variation within other traditions. It arises from our search for a sufficiently large population; many variants on the theme. There are of course variations within the apparent boundaries of larger religions and the same reviewer highlights historical diversity within Roman Catholicism. Comparative tracking of 'microevolution' within an apparent 'species' was judged beyond the research at this stage.

Borrowing again from biotic terminology in the absence of an alternative it may be that these groups have more in common with geographic 'varieties' or 'sub-species' than they do with 'species'. In Aldrich's (1999) terms they have not developed sufficiently rigid boundaries.

Provisionally entitled the Memetic Evaluation of Numerically Derived Evolutionary Lineages. A detailed description will be separately submitted. Meanwhile researchers who may want to submit this approach to critical scrutiny are welcome to contact the authors.

It is not suggested that these properties are memetic, or necessarily scientific. The data set was used as an independent test of the software. It seems reasonable however to assume that genetically related species would produce similar active principles thereby exhibit comparable toxicological/therapeutic properties.

The denominations which history shows have separated since the reformation in a process that we would regard as evolutionary, i.e. random within denomination variation was, on occasions, sufficient to generate new forms that secured their own niche in the total population of Christian religions. History records how the selection process and the attempts of established churches, or rulers adhering to them, to eradicate potential rivals was frequently a survival matter for those involved. We use the term 'clade' for groupings of denominations in the absence of an established hierarchical terminology in 'memetic' taxonomy.

Compare the observation, whose attribution escapes us, that paradigms do not change in the face of evidence; they change when the old guard finally dies or retires.

Working within the constraints of binary encoding of denominational characteristics this was the simplest method we could conceive to test the proposition.

In particular its application to market strategies of different firms appears promising.

THE SELFISH TEXT: THE BIBLE AND MEMETICS

By

Hugh S. Pyper

Dept of Theology and Religious Studies University of Leeds
The Bible into Culture Colloquium, Sheffield 9-12 April 1997

Simply in terms of the number of copies currently in existence, the Bible represents one of the most successful texts ever produced. Whereas other great texts of the ancient world have either been lost or else exist only in a relatively small number of copies, the Bible is ubiquitous. It exists in over two thousand different languages and in many of those languages it exists in multiple translations. Something identifiable with the Bible in its present form has existed for nearly two millennia. If 'survival of the fittest' has any validity as a slogan, then the Bible seems a fair candidate for the accolade of the fittest of texts.

According to the collective authors of *The Postmodern Bible*, it is a 'truism' that the bible has exerted more influence on Western culture than any other book (The Bible and Culture Collective 1995: 1). In art, literature, politics and religion, biblical thought-forms, narratives and quotations are all-pervasive. As Western culture becomes globalised, so too does the bible. It is said that between a quarter and a third of all Japanese households possess a bible, in a country where only one or two percent of the population have any Christian adherence. This is because it is regarded as essential background for a proper understanding of Western culture. One effect of the spread of western culture through trade, conquest as well as missionary activity has been the spread of a collection of ancient Hebrew and Greek texts to every corner of the globe. Where Western culture goes, the bible goes too.

The purpose of this paper is to explore more fully how the biblical texts have achieved this remarkable success. It will be obvious that the model by which I intend to do this is a Darwinian one. Indeed, I propose to turn to one of the fiercest contemporary critics of the biblical world view, Richard Dawkins. His book *The Selfish Gene* (1976/1989), itself a runaway best-seller, has popularised the admittedly controversial idea that human beings, indeed all living organisms, can be construed as the 'survival vehicles' for their genetic material.

This claim is a variant on Samuel Butler's well-known description of a hen as 'an egg's way of making another egg'. An organism is a gene's way of making another gene. More pertinent to our purposes is Dawkins' further claim that there is a strict analogy between the processes of biological evolution and the development of human culture. This idea has been taken up by Daniel Dennett who adapts Butler's epigram to read 'A scholar is just a library's way of making more libraries.' (1991: 202). It is the following further adaptation of this slogan that forms the proposition that this paper will discuss: *western culture is the bible's way of making more bibles*. In an attempt to see if and how far this rather bold assertion can be defended, we will analyse in more depth the nature of the analogy that can be drawn between biological and culture evolution and in particular the usefulness of Dawkins' concept of the 'meme' in this context.

Genes, memes and texts

In *The Selfish Gene* (1976), Dawkins contends that just as biological evolution can be studied at various levels—the gene, the genome, the individual, the gene-pool or the species—so cultural evolution can be looked at in multiple levels, from the spread of the simplest catch-phrase to the rise and dominance of the great civilisations of China or the Islamic world. In terms of evolutionary biology, the main point he argues in the book is that the clearest way to think about evolution is to work from the point of view of the smallest replicating entities, in the case of genetics, the gene. By analogy, studies of cultural evolution in Darwinian terms will proceed best by examining the smallest replicating units in culture. It is these that he designates as 'memes'.

He illustrates the concept as follows:

Examples of memes are tunes, ideas, catch-phrases, clothes-fashions, ways of making pots or building arches. Just as genes propagate themselves in the gene pool by leaping from body to body via sperm or eggs, so memes propagate themselves in the meme pool by leaping from brain to brain via a process which in the broad sense, be called imitation (1976:206).

Later, however, Dawkins becomes concerned to distinguish between a meme as a unit of information lodged in a brain and the phenotypic effects of that meme, such manifestations as the tune or the idea (1982:109).

Definitions are difficult, to say the least, in these areas. What exactly constitutes a meme or a culture defies classification and the recent literature on memes is bedevilled by shifting definitions and unsupportable generalisations and comparisons. Extravagant claims for the explanatory power of this concept have been made, including claims that the key to human self-understanding is in the new 'science' of memetics.

As the originator of the term, Dawkins has been far more modest in his assessment of the value of the concept. Dennett, who as a philosopher has written with more rigour on the subject than most, elaborates the concept of the meme in Chapter 12 of his *Darwin's Dangerous Idea* where he defines memes as 'self-replicating complex ideas which form *distinct memorable units*'. Even so, the concept remains notoriously fluid and therefore liable to abuse. How could it be applied to the bible? The bible if anything seems more like a repository of memes than a meme itself or even a 'meme complex'. In the ensuing argument, we will be using the term 'meme' for its convenience and its heuristic power in applying Darwinian insights to cultural developments but with a weather eye on its slippery nature.

The Bible as replicator

At this point, however, I want to turn to a more fruitful line of enquiry provided by Dawkins' later, more rigorous discussion of the concept of the *replicator*. This he defines as follows: 'A replicator is anything in the universe of which copies are made'. (Dawkins 1982:83). At a banal level, that is a claim that can undeniably be made for the bible and so it may be of interest to explore the ramifications of this analogy.

Note, first of all, that Dawkins carefully does not say that the replicator must be *self*-replicating. There is a fundamental point here which has often been missed. DNA is sometimes described as a 'self-replicating' molecule. In one sense this is true. Given the right environment, a molecule of DNA is capable of acting as a template so that an exact copy of itself is produced. The important point is that it needs the right environment. DNA on its own cannot reproduce itself; it needs a complex of enzymes which will guide and manage the process. In fact, it is only at the level of the cell that we find a replicating structure which can produce copies of all its parts from raw materials in a simple environment.

In that sense, the bible is no different from DNA. Shut a bible, or even two, in a cupboard and you will certainly not find more bibles when you come back. Leave a jar of DNA on a shelf, however, and it will not increase either. Only in the context of a cell, of a 'survival machine', will we find DNA reproducing. Likewise, Bibles can only reproduce through the agency of a human reader who then takes steps to ensure that more copies are produced.

The crucial point which lifts all this from the level of a truism is the way in which Dawkins then refines the concept of the replicator. He distinguishes between an active replicator, the nature of which has some influence over the probability of its being copied, and a passive replicator, the nature of which is immaterial. DNA, the replicating molecule which encodes genetic information in cells is an example of the first, in that it exerts phenotypic effects on the environment through the protein synthesis it enables, which in turn influence whether it will be copied.

Active replicators modify their environment in such a way as to enhance their own reproductive capacity. Dawkins makes a particular study of the interactions between parasites and hosts. For example at a simple level, a gall wasp larva will carry genes that encode for the synthesis of chemicals that mimic the growth hormones of an oak tree, inducing the tree to grow an unusual structure which serves to protect and feed the wasp larva. Here the wasp genes are acting on the phenotype of the oak tree, not the wasp, in a way that enhances the wasp's reproduction but which may have a deleterious effect on the tree. The relevance of this parasite/host model for the consideration of the bible will become clearer as our discussion develops.

Unfortunately for our purposes, Dawkins' example of a passive regulator is a sheet of paper which is Xeroxed. On the face of it, this undercuts any analogy between the genetic material and the bible. He goes on, however, to concede that some pieces of paper are much more likely to be copied than others because of what is written on them. They then become active replicators as they convey information which acts on the reader and her environment in such a way as to induce her to copy the text. The argument we will pursue is that in this sense, the bible is indeed an active replicator, one which alters its environment so as to increase its chances of being copied. The intriguing questions then become how the bible alters its environment to increase the likelihood of its being replicated and why it has been so conspicuously successful in this.

Dawkins goes on to discuss other aspects of active replicators. It is a fundamental point in his argument that no process of replication is infallible. Strikingly, a favoured metaphor to explain this in popular genetic texts is the variability of the biblical text in different translations or through processes of copying. Robert Pollack in his *Signs of Life* for instance, sets out six English versions of James 4:5 to illustrate the phenomenon of alleles, the existence of variant

forms of the same gene within a population or indeed an individual genome (1994:38). Dawkins himself uses the 'mistranslation' of the Hebrew for 'young woman' as 'virgin' in the Septuagint version of Isaiah 53 as an example of the potentially enormous phenotypic effects of a small change in DNA. He also provides a footnote explaining the Hebrew and Greek texts complete with citations in Hebrew, remarking that 'I suppose the scholars of the Septuagint could at least be said to have started something big' by this (1989: 16). This infiltration of biblical examples into the texts of popular genetics is an intriguing phenomenon to which we will return.

The crucial consequence of this variation is that when it occurs, some replicators may turn out to be less efficient than others at replication and so will tend to be replaced by the more successful replicators. For active replicators, whose nature affects their success in achieving replication, such variation may have a remarkable effect on their reproductive ability. Those which replicate most efficiently will, if all else is equal, come to predominate in the population.

Yet variability in itself is not enough; it must be coupled with stability. If 'successful' variants are to survive and out-compete the others, they must be conserved over time. Dawkins sets out the conditions for a successful replicator in the following slogan: longevity, fecundity and fidelity. The replicator must last long enough to reproduce, it must be capable of producing a sufficient number of copies, and these copies must be accurate. To ensure accuracy, the genetic material has a whole complex of 'editor enzymes' which repair and correct copying errors in DNA. So too the biblical text has become sacrosanct with a premium put on its accurate reproduction. The great complexes of the Masoretic apparatus and the libraries of biblical criticism which have sought to preserve the text in its 'original' form are the evidences of this.

The stability of a particular text or a particular DNA sequence, what Dawkins calls its 'longevity' is an important factor. The replicator must maintain its identity over time. Equally important, however, is its capacity to throw up variants which, when conditions change, may confer an advantage on the organisms which bear them. It is this balance between the ability to reproduce faithfully a particular variant but also to be able to produce variation if the circumstances favour it that confers reproductive success on any replicating system.

The cell and the community

The bible then operates as a replicator in a way analogous to DNA. Like DNA, it stores information which can be read and translated and which contributes to its own reproduction. This, however requires the action of another level of agency. In the case of DNA, this agent is the cell where the information contained in DNA is translated into proteins which both structure and control the host of chemical processes which are necessary to sustain the life of the cell, and therefore the reproduction of DNA. In the case of the bible, the agency is a human community which will recopy and disseminate the text.

The crucial question then becomes how the active effect of the cellular DNA on the constitution of the cell or organism which is its 'survival vehicle' is paralleled in the case of the bible. That a case can be made is evident from the fact that the analogy has been pursued in the opposite direction, notably by Robert Pollack. In his book *Signs of Life* he explicitly embraces the analogy of DNA as text.

... I have organised this book around the notion of DNA as a work of literature, a great historical text. But the metaphor of the chemical text is more than a vision: DNA is a long skinny assembly of atoms similar in function, if not form, to the letters of a book, strung out in one long line. The cells of our bodies do extract a multiplicity of meanings from the DNA text inside them, and we have indeed begun to read a cell's DNA in ways even more subtle than a cell can do (1994: 5) Molecular biology is shot through with metaphors of reading: translation, transcription, reading enzymes and the like. Pollack extends this metaphor by suggesting that the genome is like an encyclopaedia, where the volumes are represented by the chromosomes, the articles by the sets of genes encoding for a particular character, the sentences by the genes themselves. Words are domains and letters are base pairs (1994: 21).

Nor is he alone in this. Dawkins himself speaks of the tempting analogy of seeing DNA as a 'family bible' (1995: 39), a record of our ancestry, slightly different for each one of us although he quickly goes on to point out flaws in this metaphor. Dennett makes the point that the strict analogy between genes and memes can be maintained on the ground that they are both 'semantic entities', by which he means that they constitute information which can be variously encoded. A gene is not simply a piece of DNA, although to be effective it has to be expressed as such. It could equally be said to be encoded in a sequence of letters on a page, just as a meme may be contained in the pages of a book.

But as texts, both DNA and the bible have to be read. In the case of DNA this is a matter of the synthesis of RNA and through it of particular amino acid sequences in cellular proteins. In the case of a text such as the bible, the analogous process, in Dennett's view, is that its memes influence a human mind and so influence a common meme-pool as to ensure the physical survival of the text. Dennett expresses this as follows: '...memes still depend at least indirectly on one or more of their vehicles spending at least a brief pupa stage in a remarkable sort of meme nest,; the human mind.' (1995: 349)

Mere reproduction of a text as a physical artefact is not enough to ensure its continued survival as Dennett makes explicit. Copies of books will only endure so long and the relative youth of even the earliest complete manuscripts of the bible bears this out. He quotes an analogy from Manfred Eigen who points out that a Mozart symphony cannot be said to survive as a living cultural entity unless it is played and replayed and checked for continuing value against other compositions. The bible must be read and must make itself read if there is to be reproduced. Its success in achieving this is what makes it an example of a highly adaptive active replicator. In this view the biblical reader, then, acts as the site of transfer of the information contained in the text to the meme-pool in which he or she operates. The book itself encodes memes which once active in the mind lead the human agents of that meme-pool to produce more examples of the text. But like all memes, in Dennett's view, they encounter competition. People have a lot of other things to do with their time and energy besides copying bibles, indeed a lot of other texts to read. What has led to the particular success of the bible in this competition for mental space?

The viral bible

Controversially, this can best be looked at under the rubric of its 'infectivity'. In a paper entitled 'Viruses of the Mind', Dawkins gives an account of the propagating power of what he calls a mind virus (Dawkins 1993). By this term he means a piece of information which ensures its own duplication without regard to the survival of the system it exploits. Viruses are propagated differently from the genes of their hosts. For instance, influenza viruses spread by coughs and sneezes rather than by being incorporated into a viable embryo for the next generation. This means that, unlike host cells whose genes will only be propagated by the reproduction of the organism of which they are part, viral genes and viruses have no vested interest in the reproductive success of their host.

So, how would a successful 'mind-virus' operate? The problem for a virus is that it must be incorporated into the replicative machinery of its host. What is the parallel mechanism among viruses of the mind? Such a meme will have to instill in the host a mechanism of conserving the meme, and a mechanism of for propagating it. It would ideally act like the gall wasp to divert the host's energies to its own reproduction. It would also, however, be well advised to have a mechanism of conserving its variability so that any changes in the environment, including the intrusion of other foreign memes, and in particular any developments in the host's own immune system can be either countermanded or else outflanked. My tentative suggestion is that the bible instills a meme in its readers which aligns its own survival with that of the reader and his or her community. 'Your survival depends on mine' is the message that the bible gives. If the primary evolutionary drive is for survival, then a virus or a meme that 'persuades' its host that it is necessary to the host's own survival and therefore conveys a reproductive advantage will have an instant welcome into the replicatory machine. The virus becomes a symbiont, an organism which co-operates to mutual benefit with its host, rather than a parasite.

Of course, it is only in hindsight that the nature of the association can be known with certainty. It is quite possible that an organism will live quietly as a symbiont and then suddenly turn on its host at a later stage. Images of John Hurt and the parasitic alien busting out through his body wall are only too apt in this connection, but the process may be a much quieter one. It may be that a false offer of reward to the host is never cashed out. From the invader's point of view, this matters little as long as it achieves its goal of its own reproduction.

Strategies of survival

What the bible has to offer the communities it needs to reproduce is the unique variety of powerful strategies of survival it enshrines. Dawkins and other writers on memetics frequently cite the example of the 'God-meme' as a meme which has a powerful record of propagation across time and space. From a theological point of view, of course, the reduction of the complexity of human accounts of God to a single meme is a gross oversimplification. What seems to underlie their reading is rather a meme which predicates human survival on something other than purely biological grounds, which offers a space, not only for bodily survival but for memetic survival.

This has resonances with the account that Zygmunt Bauman offers of the whole enterprise of human culture. Culture, he claims, is a human construct designed to fend off the threat of death. It is a survival mechanism, which finds a way of promising a form of survival in the face of the inevitability of individual death. For Bauman, the Jewish tradition is the clearest case of the subsuming of individual death in communal survival. The individual may die, but his or her genes and memes will carry on. The duty of the individual then, in the sense of his or her best survival strategy becomes one of ensuring the survival of the group, not simply his or her own prolonged life. Christianity has adopted the alternative strategy of a promise of immortality, in that the believer's death is caught up in the context of the resurrection of Jesus. Both genetically and memetically, the afterlife of the believer is strictly irrelevant except in so far as belief in personal immortality act to sustain the continuity of the meme pool.

Both of these strategies are offered to the reader of the biblical text, together with stern warnings of the likely outcome of failing to abide by the word of the text. This is also aligned to a particular set of strategies which reinforce the integrity of the biblical text. In order to maintain continuity and identity, any organism or any gene-pool has to be able to filter out undesirable interlopers.

Again, a cunning usurper will both penetrate these defences but also quickly turn them to its own advantage, keeping out competitive genes and installing itself as the object of the host's attention. On an organismic scale, the efforts of a baby cuckoo to throw the host species' own eggs and chicks out of the nest but also its success in subverting the host's nurturing instincts to its own development are a classic case. The cuckoo succeeds in side-tracking the mechanisms of rearing the young which have evolved for the vital task of reproducing the host species.

The bible contains powerful instructions as to its own unique worth and the limits to be placed on the infiltration of foreign information or texts into the communities which propagate it. The whole process of canonisation, for instance, reveals a complex interaction between text and community which serves, for example, to oust the fledgling apocrypha and turn the community's attention to the ever-growing task of copying and commentating on the biblical text with an increased sense of its importance and of the need for its conservation.

The propagation of the text and the founding of new communities are also linked to the survival of the reader and his or her community, or meme-pool. The Hebrew bible is full of admonitions about the duty to hand down its teaching, and by implication the text, to the next generation. Secondly the text contains a strong message of evangelisation. The survival of the reader's community depends on the production of new texts and new communities. This complex of memes and of strategies forms a powerful ensemble to ensure the accurate transmission of the text.

Biblical variation

What then of biblical variability? Superficially, of course, bibles show variation. The physical appearance of the bibles on our shelves is very different from that of the scrolls found at Qumran, an evolution that has something to do with ease of reading, portability and changes in the mechanics of reproduction. In another obvious sense, the bible has evolved out of its

component parts which themselves have undergone a long process of development. It now exists in a number of forms: the Tanakh, and the various canons of the Christian churches. Despite this variation it might be argued that within each community it has on the whole developed a fixed form.

However, that form itself preserves a great variety of strategies of survival. There is an analogy here perhaps in the way in which variant genes can be maintained in a population even if they have no particular advantage, or are perhaps deleterious. In many organisms, chromosomes and the genes they contain are carried in pairs. This means that an individual may carry two different variants of any gene, such variants being termed alleles. In most cases, one of alleles is dominant, so that in an individual who carries two copies of the gene, only the dominant characteristics are expressed. The consequence of this is that the individual may carry without any disadvantage another allele which could if expressed have a deleterious effect, but might also, in changed circumstances, turn out to confer an advantage. The sexual process leads to the constant reassortment of alleles which means that the population will be able both to express the alleles of the gene but also to carry them under the cloak of the dominant phenotype.

It is tempting to speculate whether some of the redundancies and doublings in the biblical text may have a similar function in that they can preserve maverick readings. These can be ignored by the mainstream interpreters, especially if an interpretative parallel to the dominance mechanism is in play, where by that verse or passage can be 'corrected' by appeal to other verses in scripture or the perceived overall theological thrust of the material. One day, however, the alternative reading may prove of interest or use to a particular interpretative community which then propagates the bible on the basis of that alternative reading.

Furthermore, even in its canonical form the bible can still generate variety. The information contained between the covers of any given edition the bible varies and develops, especially in terms of marginalia and commentary, which may, at times, have outweighed the biblical text in terms of importance. It is only necessary to count the number of editions of the bible currently available to realise how in adapting to the needs of different communities, cultures and age groups, the contents of the physical entity called the bible can vary widely. These variations serve to widen its appeal, or in other words to enable it to gain entry to and propagate itself in a whole variety of new environments.

In this connection, one of the most obvious sources of variation and adaptive strategies that the bible is its translatability. Translation is a good trick for increasing the number of bibles—I certainly possess at least 17 versions of the scriptures and I suspect that most regular biblical readers, let alone scholars, possess more than one version, something which would be unlikely for many other books in their libraries. From the blindly functional point of view, there is paradoxical advantage for a text in being written in a dead language once it has achieved a cultural dominance in another language group. It can potentially always be re-translated because the precision of the match between the words and the meanings cannot be guaranteed in the way that the text itself insists is important. It is more open to revision than a text inscribed in the native language of a culture, except in rare instances where a text preserves an older form of the evolving tongue. It is possible, for instance to find modern language paraphrases of Shakespeare, but there is a great resistance to producing new English versions of his works, whereas once the

interesting conservatism over the Authorised Version was broken, the floodgates of new biblical translations opened. Additionally, there is implicit permission for the text to be translated into the vernacular language of any community which uses the book, again increasing both its diversity and adaptability but also the sheer numbers of copies in existence.

This is by no means a one way process. The success of the bible in reforming the communities into which it moves through translation is also striking. As Carroll and Prickett observe in their introduction to the World Classics edition of the Authorised Version

What we *can* observe is that it was not just the Bible that was transformed in the course of successive reinterpretations. The Vulgate, a single, authoritative, monolingual instrument for the entire Western Church, was the instrument of the new imperial power of the Roman Church. Luther's Reformation translation of the Bible was to change the German language for ever; his commentary on Romans to set the agenda of theological debate for centuries. Tyndale's translation of the New Testament, on which the Authorised Version was to be so closely modelled, did the same if not more for English. (Carroll and Prickett 1997: xiv-xv)

Communities based on the bible may have a strong interest in conserving it unchanged. From the point of view of the bible, however, its ability to adapt to new communities is an essential part of its success. The fact that much human ingenuity has been expended on ensuring that the bible does *not* change and that such mutations have at times been physically rooted out merely goes to show the strong pressure on the text to mutate and its potential for evolution. As we noted before, the interests of the text and those of its nurturing community may not coincide.

This leads to the conclusion that when another champion of scientific realism, the astronomer Carl Sagan, lays into the Bible in his attack on what he conceives of as superstition in his recent book *The Demon-haunted World* he in fact reveals one source of its reproductive success. Contrasting the love of one's enemy enjoined in the Gospels with the celebration of holy war of Joshua, he writes 'The Bible is full of so many stories of contradictory moral purpose that every generation can find scriptural justification for nearly any action it proposes, from incest, slavery and mass murder to the most refined love, courage and self-sacrifice' (1996: 275). Indeed, and this has surely contributed to its survival. A book to which both the Apartheid regime in South Africa and its most fervent opponents can turn to justify their position may not offer simple moral precepts, but does ensure that both sides will own their own copies. For the survival of the *book*, its amazing capacity to sustain opposing camps is a very successful strategy. Part of its success is its very diversity, but also the fact that diversity can be differently enacted. As is well known, every cell in the human body contains the same genome, but this is differently expressed in different tissues to give cells which vary radically in form and function. The difference is the particular portions of the genome which are read. So too the bible contains more information than any one community can readily assimilate, especially as it may seem mutually contradictory or impossible to apply in a given situation. What then happens so often is the formation of a canon within the canon, where the community opts to read and follow a particular smaller set of instructions, read with a particular interpretative slant. This may change over time, giving a flexibility and yet continuity to the community. Biblical communities themselves show a capacity for survival which consists in a knack of maintaining continuity through change.

Biblical advantage

It was allegedly the physician to Frederick the Great who when asked by that monarch to give a proof of the existence of God replied 'The continued existence of the Jews'; an existence bound up with the identity, adaptability and continuity that the bible confers. In a more theoretical vein Sir Peter Medawar attributes the biological success of human beings as a whole to a new form of inheritance; exogenetic or exosomatic heredity. 'In this form of heredity, information is transmitted from one generation to the next through non-genetic channels—by word of mouth, for example, and by other forms of indoctrination; in general by the entire apparatus of culture' (1977: 14; quoted in Dennett 1995:342). Henry Plotkin in his *Darwin Machines and the Nature of Knowledge* cites the Bible and the Koran as just such devices of exosomatic storage. He speculates on the selective advantage of such texts to the cultures which retain them by drawing on Bartlett's work on the degradation of oral narratives which implies that over time any group will retell a tale in such a way as to bring it into line with accepted norms. Plotkin argues that the 'exosomatic storage of memes' in the bible may have preserved 'richness subtlety and beauty' in cultures which possess the book (1994: 220).

That continuity is bound up with the continued existence of the bible. The community of readers sees it as its duty to ensure the survival of the book. More than this, it sees the book as the guarantor of its own continuity and survival. The book itself contains a whole plethora of strategies for survival, and in particular, is the record of an amazing feat of cultural continuity as the diaspora communities of Jews manage to retain a sense of themselves as Israel, as members of one 'meme-pool' of cultural exchange, protected by firm filters from external memetic contamination. The fact that historians might take leave to differ over the actual continuity of the community and its immunity to outside infection is surely a proof of the power of the meme complex in question. Despite the available evidence of all that might have led to its dissolution and disappearance, the community is maintained, and the text is preserved.

Even more amazing is the development of communities of those supposedly excluded by the text, the Gentiles, who find ways of identifying themselves as Israel and arrogating to themselves both the promises and the duties imposed by the text, chief among which is the duty to ensure the connivance and dispersal of the text. Here the 'gene-pool' of Judaism, with its claim of descent from Abraham, is replaced by a meme-pool, a claim of descent from Abraham's faith, a line of argument already presaged in the Old Testament itself.

This is an astonishing success and one of crucial importance to the propagation of the text. The consequence of its incorporation into the canon of the Christian bible is an exponential leap in the number of copies produced. However, it may also be true that the text turns against the communities that have sustained it if that is to its advantage.

The horrid record of Christian anti-Semitism shows the consequences of the reappropriation of the filter mechanisms for memetic purity being turned against the original host community as the bible takes on a new existence as Christian Scripture. A prime exemplar of the selfishness of the text might be seen in the reformation where the text operates to cause a major breach and disruption in the community which sustained it in order to take advantage of the new technology of printing through the propagation of a meme that removed the authority of interpretation from

the institution to the individual and to the possibilities of reproduction within vernacular language communities. The peril of too close an association with the host community may be that the text will fall with the community that guards it. The success of the bible has been predicated on its ability to 'jump ship' when necessary.

Again, this is a slightly self-parodic example of the prevalence of the intentionalist fallacy in the discussion of Darwinian replicants. It is patently a fallacy to argue that the bible provoked the Reformation in order to increase its own population, but the facts remain. Whatever damage the Reformation did to the church and to the victims of the religious wars that accompanied it, it was certainly good for the bible.

The survival of the bible

What then of the bible in late twentieth century society where the traditional communities of interest in the bible may be thought to be in danger of collapse? Selection is a cruel business as many species and their DNA find every day. Surviving intact for a hundred million years is no defence when your habitat is suddenly filled with industrial pollutants. The best that can be said for any replicator is that it has survived *so far*. Tomorrow is another day and will perhaps bring an insurmountable challenge.

Even if the worst comes to the worst in terms of a diminishing community of biblical readers, the important thing for the text in a memetic view is not that it be read but that it be copied. By achieving an iconic status within a culture, the text can relieve itself of the pressure of seducing readers. The baptismal bible or wedding bible may be a gift that is never read, and no-one is likely to open the pages of the court room bible on which oaths are sworn, but they must be complete as the community is well endowed with reverence for the canon that says 'all or nothing': an incomplete bible is not a bible. This may work more powerfully for the New Testament than the Old, as the New circulates independently, but it nonetheless still allows for the reproduction of redundant, unread material within the New Testament. This, in turn, will allow for the introduction for the sake of iconic completeness of the even less appealing Old Testament [1]. So the bible can survive in some sense on the vestiges of a culture which valued it.

However, the situation is by no means as gloomy as that. As I was finishing this paper, by coincidence two documents arrived together in my pigeonhole. One was a copy of a review of several modern popular debunking biographies of Jesus, including that by A.N. Wilson, which finished with the comment from an eminent critic, 'At least he sends us scurrying back to the gospels'. The second was a leaflet from the National Bible Society urging donations for the dispatch of bibles to the displaced and starving population of Zaire.

Whatever one thinks of the anti-biblical polemics of an A.N. Wilson and the response of the Bible Society to the disasters of war, there is a common feature to these documents; both seem to serve to increase the sale and distribution of the bible. The Bible Society can still launch an appeal to increase the number of bibles in the belief that the bible will contribute uniquely to the survival of the people of Zaire. A.N. Wilson, who seeks to debunk it and would no doubt pour scorn on the Bible Society's work finds himself both propagating biblical memes in his own texts

and sending his readers back to consult the original text. The biblical text is not affected by the fact that the person who reads it is only doing so to refute it as long as there is a sufficient cultural community or meme- pool to maintain the argument and therefore sustain the need for the text.

Yet the bible has always shown an astonishing facility in generating communities that will see it as worth transmitting. What memetic pull is it that brings together a group of scholars of diverse backgrounds and beliefs to Sheffield to discuss the bible and culture, for instance? Has the bible 'succeeded' in making a bid beyond its native environment of the religious community, one which may be severely threatened in a new memetic ecology. Is it now able to persuade communities of readers to consider it as a cultural artefact, using the same memetic appeal as Homer and Plato? If so, what a tribute to the extraordinary staying power of the particular combination of memes which the text and the communities it builds around itself enshrine. Having formed communities about itself for two thousand years, often by co-opting its enemies, is the bible proving able to do this again by infiltrating not religious but cultural discussion?

A telling example of this ability of the biblical text to infiltrate the most unlikely communities is the very genre of popular genetic writing of which Dawkins is the most celebrated practitioner. For someone who evinces such a suspicion of the influence of the bible, he makes a surprising number of references to it. His main rival, both as a best-selling writer of popular genetics and as advocate of what to Dawkins seems a 'heretical' view of Darwinism is Stephen Jay Gould, whose books are shot through with biblical allusions. Another populist geneticist, Stephen Jones', recent book, *In the Blood: God, Genes and Destiny*, a companion to a television series, is an interesting case in point. In it he covers such topics as the Lost Tribes of Israel and the concept of Armageddon, in the process alluding to a large number of biblical texts and outlining many biblical stories. It would be ironic, would it not, if we were to conclude that Dawkins himself has become a 'survival machine' for the bible, a 'meme nest' for its dispersed memes which may induce readers who would otherwise leave their bibles unread to go back to the text.

Dawkins, however, is merely one articulate representative of a much wider conversation in a global gene pool which could loosely be designated as 'western culture'. Insofar as we have seen that the survival of the bible seems to be predicated on the persistence of its peculiarly effective set of memes which induce reading communities to propagate it, it is Dawkins inescapable cultural environment which is in evidence here.

But are we then simply the victims of the bible? Dawkins ends *The Selfish Gene* with a rallying cry 'We are built as gene machines and cultured as meme machines, but we have the power to turn against our creators. We, alone on earth, can rebel against the tyranny of the selfish replicators' (1976; 215). Is he actually a witness that we may think we can rebel against biblical memes but that such replicators have an uncanny power to survive all our efforts? The telling passage in his *River out of Eden* (the title itself needs no comment) on the 'ravishing' poetry of the Authorised Version of the Song of Songs, and the 'lifetime's repetition' which has given it its own haunting appeal despite the possible inaccuracy in translation (1995:40) argues that aspects at least of the bible have succeeded in inserting themselves into the 'meme nest' of Dawkin's mind in such a way that they are transmitted, if not replicated.

Dennett comments on Dawkin's challenge to the power of the memes, 'This "we" that transcends not only its genetic creators but also its memetic creators is ... a myth.' (1995:366). Dennett himself ends his 1995 book with an ambivalent plea for the preservation of meme complexes such as religions for their cultural enrichment. 'I love the King James Bible', he declares. 'My own spirit recoils from a God Who is He or She in the same way in which my heart shrinks when I see a lion pacing neurotically back and forth in a small zoo cage. I know, I know, the lion is beautiful but dangerous; if you let the lion roam free it would kill me; safety demands that it be put in a cage' (1995: 515). This is a rather extraordinary paragraph which is somewhat baffling in its implications. What is it that distresses Dennett so much? It seems to be the use of gendered language of God, not the idea of God. Is the King James Bible the cage, in which case what is the love he bears it, or does it need to be in the cage with the lion because of its dangers?

My own view, and no doubt I here manifest symptoms of my own freight of memetic viruses, is that the bible has so firmly entrenched a place in our culture that it is ineradicable. It is not a parasite but a constituent part of the great complex of meme complexes that can be designated 'western culture', part of the exosomatic genome of that culture's members. More than that, I see it in Plotkin's terms as an indispensable source of what might be called 'memetic diversity.' In agricultural genetics, one of the most worrying trends has been the loss of diversity from the appellations of food plants and animals. There are obvious superficial gains, not least to seed companies and fertiliser manufacturers in growing vast tracts of pure stands of the 'best' varieties, the judgment of 'best' depending on the particular values of the grower or the market. Ease of marketing may well win out against nutrition. However, there is a potential disaster looming if the super variety is suddenly attacked by a pathogen or if there is a major climatic shift. A variety may be fit for the purpose and the conditions of the moment, but what if conditions change?

Here it becomes vitally important to maintain a 'gene pool' of wild relatives of the crop plants which may themselves have all sorts of drawbacks from the point of view of the technology of farming, but which have shown themselves able to fend for themselves in this competitive world over time. Such wild populations contain a huge diversity of genetic material maintained over time and a vast potential for diversity and for change. Can we view the Bible as a sort of cultural 'memetic reserve'? Parts of it may seem irrelevant, redundant, even detrimental to our survival, but it has kept going. As Medawar and Plotkin indicate, it may serve to maintain a memetic richness and complexity, an inexhaustible source of variety which may contain the unexpected counter to forces that threaten to impoverish our cultural lives.

But Dennett's rather inarticulate declaration of love for the bible suggests other possibilities. This paper has, of course taken a slightly wry look at a provocative re-reading of the dynamics of cultural development. Nothing in the theory of memetics can help us to establish the truth or falsity of a meme; it can only deal with its frequency and prevalence. Questions of reference are not raised. Indeed, the practitioners of memetics have erected some pretty formidable filters to debar any such questions. Methodologically, this may be necessary to prevent muddled thinking, but methodology is not truth despite its strong tendency to become so. The easiest way to filter out a proposition is to declare it to be either meaningless or false. A very different account could have been given on the premise that the bible reflects the encounter of God with the complex web of human culture and individuality, a premise which *methodologically* Darwinism cannot

entertain. The attempt, however, to follow through such a methodology is a discipline which I hope has brought to light intriguing connections which any account of the relations of the bible and culture might need to take on board.

More radically, however, is survival, as Darwinism must have it, really the primary value, or is it in turn a methodology which has become a truth? The lion may be dangerous, and human culture as Bauman argued may well have been a device to keep it caged and to ensure survival, just as the wild lion has been confined practically to game reserves. The beauty of the cage, then, is in some sense engendered by the lion. Letting the lion out would have disturbing implications for culture as well as for scientific method. But is there no other mode of co-existence between human and beast, between human beings, the bible, and the God which it cages and displays? Here I want simply to recall that Isak Dinesen has a wonderful account of the mutual respect between the hunter and the lion which grows from the fact that each knows that the other is hunter as well as prey. Somewhere in this may be a dynamic that can lift us beyond the mechanisms of the meme and into true encounter.

Footnote

The Bible carries a great deal of seemingly redundant information: the detailed instructions for the construction of the tabernacle, for instance. Intriguingly one of the more unexpected findings of molecular biology is that a large proportion of the DNA in any genome is seemingly also redundant, consisting of simple repeating sequences which do not encode any gene. This redundant DNA is, however, copied and transmitted to the next generation as faithfully as any other. Opinion is still divided as to the function of this material. It may have structural or geometrical implications.

Abstract

Imitation has been put forward as a defining feature of memetic transmission. Since there is currently poor evidence for imitation in non-human animals, such definitions have been interpreted as restricting meme theory to the study of human behaviour patterns and birdsong. We believe this is a mistake. Human capacities for imitation, teaching and language may well account for the extraordinary diversity of human culture compared with animal proto-cultures, but imitation is simply one mechanism of transmitting acquired information between individuals. As long as information is transmitted with sufficient fidelity to be replicated in the brain of the receiver, any social learning process will do. Non-human animals may be poor imitators, but many are excellent social learners. We argue that the meme concept can, and should, be applied to animal cultural transmission.

Keywords: social learning, cultural transmission, acquired information, animals, imitation, replicator, meme.

1 Introduction

In her recent book *The Meme Machine* Susan Blackmore (1999) suggests that what makes humans special in comparison with other animals is our extraordinary capacity for imitation. According to Blackmore, imitation is the linchpin of meme transmission, and as evidence for imitation in animals is weak, humans alone can be regarded as possessing and transmitting memes.

In this article we present a counter position to Blackmore's, arguing that animals should be allowed the right to carry memes. We present our arguments, not as a criticism of Blackmore's position, but rather in an attempt to open up an informed debate over this interesting issue. We agree that evidence for non-human animals routinely imitating is weak, but argue that imitation need not, and should not, be the defining feature of a meme. Transmission fidelity, not the psychological process underlying transmission, is a determining feature of whether a meme can spread and replicate.

2 Imitation and the meme

The definition of the term 'meme' has been the subject of some controversy (e.g. Rose 1998). However, transmission of acquired information by imitation is a common element to many

definitions. For example, a meme has been defined as "*an element of a culture that may be considered to be passed on by non-genetic means, esp. imitation*" (Oxford English Dictionary), as "*a unit of imitation*" (Dawkins 1989, p.192), and as "*whatever it is that is passed on by imitation*" (Blackmore 1999, p. 43). In these definitions the use of the term 'imitation' is frequently qualified by the phrase "*in the broad sense*" (Dawkins 1989, p.194; Blackmore 1999, p.7 and p.43). Indeed, Dawkins's first definition of the term appears to equate imitation with all kinds of cultural transmission processes ("*[a meme is] a unit of cultural transmission, or a unit of imitation*", Dawkins 1982, p.192, reversed original italics), and includes examples of cultural transmission such as the spread of milk bottle opening in British tits (Fisher & Hinde 1949; Dawkins 1982, p.109). Other authors do not specifically address this issue, but use the term 'imitation' to refer to social learning processes in general (Bonner 1980, p.18 & p.165; Goodenough 1995) and agree that animals possess memes (Bonner 1980, p.188). Blackmore however explicitly excludes all non-imitative forms of social learning as capable of transmitting memes, and so, with the exception of birdsong, restricts memes to humans (1999, p.49).

There is little doubt that animals regularly acquire learned information from one another. The term 'social learning' refers to learning that is influenced by observation of, or interaction with, another animal or its products (Box 1984). Experimental investigations have revealed that imitation is just one of several processes that can result in social learning (Galef 1988). There exist numerous reports of novel behaviour patterns spreading through animal populations through social learning processes (for reviews see Lefebvre & Palameta 1988 or Galef 1988). Famous cases include termiting in chimpanzees (Goodall 1964), food washing in Japanese macaques (Kawai 1965), the opening of milk bottles in British birds (Fisher & Hinde 1949), dietary preferences in rats (Galef 1996), birdsong (Jenkins 1978), and fear of snakes in rhesus monkeys (Mineka & Cook 1988). In the majority of cases where the transmission process is investigated, behaviour patterns are not transmitted by imitation, but instead result from other, simpler processes such as local enhancement, where an animal's attention is drawn to an object by the actions of another, in a manner that results in learning (Galef 1988). Yet animals clearly have behavioural traditions based on acquired information transmission. Moreover, many of these animal traditions appear to change over time (e.g. Gibbs 1990) in a manner perhaps consistent with the predictions of memetic evolution.

So why do researchers place such a premium on imitation? It would seem that, for Blackmore, the key to memetic transmission is that something is learned about the form of a behaviour rather than about the environment (1999, p.49). For example, Blackmore argues that milk bottle opening in British birds is not a meme since "*the tits already knew how to peck; they only learned what to peck*" (Blackmore 1999, p.49, reversed original italics).

However, while in the past definitions of imitation have stressed the learning of a new behaviour through observation (e.g. Galef 1988), it is now widely recognised that imitation is not solely, and may rarely be, concerned with learning a new motor pattern: imitation is also concerned with learning the context and consequences of an established motor pattern (Heyes 1993; Heyes 1996, p.381). For illustration, consider the case of someone learning to play tennis through imitation. Here the apprentice is not learning to run, hold racket like objects, hit things or wave their arms around - all of the required motor patterns are already part of their repertoire. They are learning to move their body in a particular way (for instance, to move the racket towards the ball), at a

particular time (when the ball is approaching), to generate a certain result (to hit the ball in the desired manner). The tennis playing meme is not exclusively concerned with motor patterns: it is a complex of information that also concerns the location appropriate for the behaviour, the objects with which one interacts, and the consequences of the behaviour. To take another example, this time the 'making pumpkin soup' meme described by Blackmore (1999, p.61), we have a case where the recipient of the new recipe is not preparing food, cooking, or even making soup for the first time. The cook is simply carrying out an existing motor pattern (that of making soup) with an ingredient novel to the soup-making context but familiar in other contexts.

Exactly the same logic applies to the milk-bottle-top opening birds. They are not learning to peck any more than the tennis apprentice is learning to run around or hold rackets: that motor pattern is already part of their repertoire. They are learning to peck a particular object (the milk-bottle), found in a particular location (on a doorstep), to generate a particular consequence (the cream reward). Similarly, Japanese macaques are not learning to move their hands in water; they are learning that if they move particular objects (the sand-covered sweet potatoes) in water they can generate a desirable reward (that is, sand-free food). Imitation is not a criterion upon which the meme-carrying of animals and humans can be distinguished.

3 Reconstructed memes

A second, but related, objection to allocating meme status to animals is that in cases of animal social learning most or all of the meme is not transmitted, but rather reconstructed. To quote Blackmore once more, "*other forms of social learning do not support a replication system with true heredity, because the behaviour is not really copied*" (1999, p.50). To remain with the milk-bottle-opening example, current experimental and theoretical analyses (Lefebvre 1995; Sherry & Galef 1984) concur with Fisher & Hinde's original conjecture that the majority of birds have learned the behaviour pattern in some way from comparatively few individual innovators. There is no evidence that the birds transmit any more information than a tip-off that milk bottles contain cream (Hinde & Fisher 1951), but that is enough for each observer to reconstruct the behaviour of milk-bottle opening. Here it is the meme for milk-bottle opening that is transmitted, not the specific opening technique, which is quite variable even within individuals (Fisher & Hinde 1949). This reconstruction process is very different from the direct copying of DNA, and leads Blackmore to question whether it is legitimate to describe such a process as replication. Yet while this particular meme may not be directly copied, it none the less appears to be replicated with unerring reliability. The first report of milk-bottle opening was in Swathling near Southampton in 1921 (Fisher & Hinde 1949) and since then, it has spread throughout Britain, into several other European countries, across to tens of other species, and is apparently still prevalent some 75 years later. If fidelity in the form of reliable reproduction is a criterion upon which memes are judged, milk-bottle-top opening will surely qualify. It is highly likely that cream-drinking is just one element of these birds' socially learned foraging repertoire, implying that other feeding memes may have exhibited a corresponding decrease in frequency. There is no reason to think that the birds could not institute a mutant variation to exploit some other food source.

This raises a policy decision for memetics. Should reconstructed memes count as genuine memes? We argue that they should for two reasons. First, virtually all memes, including those of

humans, involve an element of reconstruction (Sperber 1996). Humans when they imitate rarely do so perfectly, and they are typically forced to re-evaluate and adjust their behaviour in the light of sensory feedback (Piaget 1962; Yando et al. 1978; Custance et al. 1995). To argue that largely reconstructed memes are not memes would require an arbitrary and unenforceable rule to be employed regarding just how much reconstruction is allowed before acquired information qualifies as a meme. Reconstruction cannot be quantified in any meaningful sense. Second, reconstructed memes fit the Darwinian model as effectively as perfectly transmitted memes. They too can replicate and evolve, and to eliminate them on arbitrary grounds at this early stage in the science of memetics risks eliminating a large number, maybe even the majority, of interesting cases of social transmission that may benefit from memetic analysis. What counts is not how transmission occurs, but whether the product is similar in the transmitter and receiver - in other words, what counts (amongst other things) is fidelity (Dawkins 1989).

4 Information versus phenotype

A further criticism of memetic definitions based upon imitation is that emphasis is shifted from the transmission of information to the transmission of that which is imitated, i.e. behaviour patterns, or the memetic phenotype. Delius (1991) was explicit on the fundamental nature of this distinction, stating, "*memes stress the transmittance of coded information rather than of behaviour itself*". Delius defines memes as "*synaptic patterns that code cultural traits*" (where cultural traits are "*behavioural items acquired through social learning*"). Boyd and Richerson made a similar point, arguing, "*the essence of culture is encoded information rather than the behaviours that result from this information*" (1985, p.43). This discrimination is important, since it seems entirely feasible that the same meme could produce very dissimilar behaviour patterns in different individuals or in different circumstances (see e.g. Boyd & Richerson 1985, p.41-43), and that identical information could be learned from different behavioural performances (Sperber 1999). For example, the meme for making pumpkin soup could be transmitted by a perfect demonstration of the technique, or by a demonstration riddled with obvious mistakes. Prior knowledge of cooking would ensure that the meme for soup making was reconstructed accurately, without the inclusion of such mistakes.

5 Birdsong: a special case?

Although animals in general are frequently regarded as not having memes, researchers commonly make an exception of birdsong. However, learning a song does not involve learning a novel motor pattern, and would appear on the surface to be inconsistent with Blackmore's criteria for memes. Yet perhaps we are being pedantic, since the acquisition of birdsong involves the social learning of novel behavioural elements, if vocalizations can be regarded as such. Moreover, no doubt, most birdsong meme enthusiasts regard song learning as a form of imitation. Yet social learning theorists have long made a distinction between vocal and motor imitation (Galef 1998; Heyes 1994). The former is regarded as a less challenging form of social learning, since there is a greater correspondence between the sensory feedback from the learner's own vocalizations and those of its tutors than in motor imitation, for which the sensory experiences of *doing* and *seeing others do* are typically very different. What is more, birdsong is a highly restricted form of social learning, different from the general capacity for social learning found in humans. The processes underlying song acquisition allow birds to learn song and

nothing else. That is not to say that songbirds are incapable of other forms of social learning, but rather that these other forms probably rely on alternative mechanisms to song learning. Whatever the processes underlying birdsong, there is no evidence that they are more similar to the processes underlying human culture than other forms of animal social learning.

So why is an exception made of birdsong? We suggest two reasons, both unconnected to the psychological processes that underlie learning. First, Dawkins mentions birdsong in *The Selfish Gene* (1989, p.189). Dawkins's authority carries a great deal of weight in memetics, and if he says birds have memes that is enough for many. Second, birdsong has been subject to some of the most elegant empirical work on memes (e.g. Burnell 1998; Lynch 1996; Lynch et al. 1989). It turns out that birdsong lends itself to the meme concept beautifully, perhaps better than almost anything else, even human culture. We would welcome similar memetic analyses of other forms of animal social learning.

6 Memes in non-human animals

We end with three illustrative examples of cultural transmission in non-human animals to which meme theory may profitably be applied. First, an example from the apes. In a recent synthesis of long-term field studies of chimpanzees across Africa, Whiten et al. (1999) documented "*significant cultural variation*" after ecological explanations for this variation were discounted, with 39 different behaviour patterns identified that are traditional in some communities but absent in others. An earlier paper by McGrew (1994) reached similar conclusions. Whiten et al. (1999) argue that these behaviour patterns are most likely acquired by a mix of imitation and other processes that can result in social learning, but Whiten (personal communication) agrees that these different behaviour patterns can be classed as memes, as defined by the Oxford English Dictionary, especially in the sense that Boyd and Richerson (1985) emphasized. For example, the essential 'idea' of ant-dipping by the two-handed method used at the Gombe National Park has been observed in several successive generations, despite minor variations in its manifestations (Whiten, personal communication). Cultural variation has previously been identified only for single behaviour patterns in non-human animals, such as the local dialects of song-birds, and it may be possible to examine the dynamic relationships between the different memes which make up chimpanzee proto-cultures.

The meme concept need not be restricted to animals phylogenetically close to humans. In an experimental study, Curio et al. (1978) demonstrated that observer birds could learn to mob a non-raptorial bird, and even a plastic bottle, as a consequence of witnessing another bird mob at its presentation. This behaviour was transmitted along chain of six individuals, with each individual acting as a demonstrator for the next bird in the chain. Here a meme for the context in which mobbing is an appropriate response is transmitted. However, there were limitations to what could be transmitted. For example, birds did not learn to mob an empty cage, and learned to mob the plastic bottle stimulus less strongly than the bird stimulus. There may be similar restrictions on the successful transmission of human memes.

Third, an example from fish. Mating sites of the bluehead wrasse (a coral reef fish) have remained in daily use over 12 years (four generations) without changing location (Warner 1988). There was no obvious correlation of sites with resources, and many more potential mating sites

available. Entire populations were experimentally replaced, and the transplanted populations chose new sites; but where females were transplanted to locations containing native females, the newcomers only mated at established sites, implying that tradition rather than resources is important in determining mating site location. After further experiments Warner proposed that these arbitrary traditions were probably transmitted by females following one another (Warner 1990), a very simple social learning process. Here we have an example of a long-lived, arbitrary tradition transmitted without imitation. Again, we can consider the mating site preference that each fish learns as a discrete, replicating unit of information, and examine the diffusion dynamics of these memes.

7 Conclusions

We argue that a defining feature of a meme is that of a culturally transmitted replicator. The proposed memes in our examples show the three characteristic qualities of replicators detailed by Dawkins: copying-fidelity, fecundity, and longevity (1989, p.194; see also Dennett 1995, p.343). As such, these proposed memes seem as likely as any human meme to undergo evolutionary processes through heredity, variation, and selection. Hence we believe that memetics should not prematurely rule out these animals' memes. Indeed, animal social learning may be a useful testing ground for the meme concept. After all, it is entirely plausible that in future years animal social learning may eventually be judged to fit the meme model better than human culture.

Abstract

The goal of this research is to assess the impact of Culture on decision-making behavior. Specifically we are concerned whether the emergence of human culture provided humans with an adaptive advantage over non-human primate counterparts in terms of hunter-gathering capabilities. Reynolds has proposed several mathematical models of hunter-gatherer and primate decision making based upon differences in human and primate cultural traits [1]; these were labeled the cultural algorithm and vector voting models respectively.

In this paper an agent-based implementation of the vector voting model using Swarm is presented. Learning takes place in the model by emulation. The performance of this model in a variety of patchwork landscapes is compared with that of a random walk model. The impact that the distribution of food resources has on the outcome is also tested using several different strategies such as equal sharing, round robin, satisfied first, neediest first, and fixed rank order. The results suggest that the vector voting model performs best when certain resource sharing strategies are used (fixed rank order, satisfied first) as opposed to others such as neediest first, and equal sharing. In the latter case it behaves equivalently to a random walk. Thus, when knowledge is not shared equally, it is not adaptive to share resources equally either.

1 Introduction

The goal of this research is to assess the impact of Culture on decision-making behavior. Specifically we are concerned with the question of whether the emergence of human culture provided humans with an adaptive advantage over non-human primate counterparts in terms of hunter-gathering capabilities. Reynolds has proposed several mathematical models of hunter-gatherer and primate decision making based upon differences in primate and human cultural traits [1], these were labeled the vector voting and cultural algorithm models respectively. In the vector voting model each individual's vote was based upon their own knowledge and knowledge was not shared between individuals. The decision made by the group was a consensus based upon the weights and opinions of the members and was modeled after the patterns of interaction seen among primate groups. In the cultural algorithm model the individuals' knowledge was pooled and used by a central decision maker to produce a decision.

The basic context in which these two decision-theoretic models were compared was a two-dimensional cellular space divided into R discrete sub-regions or cells each of unit area. The task facing the model groups was to compute the answers to various spatial predicates or queries about the region based upon the agents' current knowledge. The models were analyzed theoretically and it was shown that the ability to form a collective intelligence through the pooling of knowledge with Cultural Algorithms had some distinct advantages over the vector voting model.

In particular, predicates such as the best direction within a region in which to forage, the direction containing the most resources, was limited by the maximum area over which each individual had knowledge. On the other hand, pooling of that knowledge theoretically allowed a group to make these decisions over the entire region.

However, even in a social system where knowledge is not directly pooled, learning can take place. For example, Tomasello and Call [2] state that there are many similarities between how humans and primates understand their social worlds. Each has its own cultural system. In an extensive survey of primate cognition studies they conclude that, "*all primates live in basically that same type of social world, in which they individually recognize conspecifics and appreciate both the vertical (dominance) and horizontal (affiliative) relationships that hold between group members. They also have the ability to predict the behavior of conspecifics in many situations based upon combinations of cues and insights, and in some cases to affect the behavior of group mates via various social and communicative strategies.*"

They state that the basic difference between primate and human cultures is that in the latter the "*inter-subjectivity of human linguistic symbols- and their perspective nature as one offshoot of this inter-subjectivity- means that linguistic symbols do not represent the world directly, in the manner of perceptual or sensory-motor representations, but rather they are used by people to induce or construe certain perceptual and conceptual situations in order to attend to them in one way rather than another*".

Thus, learning in a primate social system relies heavily on **emulative learning**. An individual watches another perform an action and observes the state changes that result. Learning in this context is directly associated with sensory motor activities relative to objects in the environment. While humans can acquire knowledge in this way as well, they are able to support the **imitative learning** of concepts. With imitative learning "*an individual understands others as intentional agents, like the self, that have a perspective on the world that can be followed into, directed, and shared.*"

The idea is that even when a group makes a decision based upon the knowledge of each individual without pooling, the physical results of that decision can be observed by everyone and learning can take place in an emulative fashion. The question of interest in this paper is what additional behaviors emerge from a group that uses the vector voting approach along with an emulative learning process. Specifically, to what extent do behaviors typically observed within a primate foraging group emerge from the use of the vector voting model? In future studies we will examine the impact that adding communication and abstraction capabilities in the form of Cultural Algorithms has on these patterns of behavior.

Here we develop an agent-based implementation of the vector voting model using the Swarm Simulation environment. In section 2 we describe the theory behind the vector voting model and the emulative learning method that serves as the basis for the primate cultural transmission here. In section 3 the Swarm implementation of the vector voting model with emulative learning is presented in detail. Next, in section 4 we describe the results of running this model in a variety of environments with a variety of social configurations. Specifically, we use our system two sets of experiments. Our first set of experiments is used to determine whether the vector voting model outperforms a baseline model which performs a simple random walk through the landscape. We also observe any generalized behavior patterns that emerge from the model group. The second set of experiments is designed to observe how differences in social interaction effect the performance of the vector voting model. Here, we propose several different ways of distributing the collected resources including approaches based upon dominance and equal sharing. We then attempt to identify which form of distribution works best in conjunction with the vector voting model. Section 5 provides our conclusions.

2 Implementing Cultural Transmission in the Vector Voting Model

The vector voting model represents how primate groups might make consensus based decisions. Human hunter-gatherers can also employ this technique as well and one assumes that human cultural systems are able to build upon the capabilities of the vector voting approach.

The motivation for the vector model can be seen in the following quote from Kummer [3, p. 66], *"In choosing the direction of their departure, hamadryas baboons have to rely on information gathered on previous trips. We do not know how or by whom these sites are explored and remembered, but we know that on different mornings different males of the troop strive in different directions. The decision is made by a long process in which most of the males in the troop participate while the rest seem unconcerned. I have already described how a hamadryas troop prepares for departure during its morning rest. The troop performs slow on-the spot movement, changing its shape like an undecided amoeba. Here and there, males move a few yards away from the troop and sit down, facing in a particular direction away from the center.*

Pseudopods are generally formed by the younger males and their groups, until one of the older males in the center rises and struts toward one of the pseudopods. At this, the entire troop is alerted and begins to depart in the indicated direction. Detailed observation reveals that two male roles are involved in leading the hamadryas troop: the younger initiators who "propose" certain directions and the deciders who choose among the proposed directions."

One of the basic decisions that a foraging group can make is the direction in which to forage during the day. It was shown in [4] that it was not possible for a vector voting model to always select the direction with the maximal amount of resources within a region R. However, theoretical limits aside how does the vector voting model actually perform when coupled with emulative learning, the type of learning that is frequently observed in primate cultures.

In emulative learning the observer makes a cognitive connection between what action is performed and the state changes it produces. For example, a primate can observe another rolling over a log and exposing a number of insects. That action can be viewed as producing a state

change which can be stored in memory. In our model, the result of a directional decision produces a trajectory through the landscape. As a result of that path each individual has an opportunity to acquire food. In each cell that the group enters the resources there are divided among group members by various strategies such as priority or fixed order access or equal sharing of resources.

At the end of the day each individual can store a memory, not of the decision, but of the result. An individual does this by associating a visible landmark with the degree to which they were fed (satisfaction scale) the day they saw that landmark. A memory can more than one landmark attached to it and different individuals in the group can associate different landmarks with their memory. The memory made by an individual is a function of the food resources that they received that day. Each individual has a maximum number of memories that it can store and a memory is forgotten after a certain number of days (memdepth) unless it is used again.

Emulative learning using memories associated with the icons encountered relative to a group's previous decision can now be used to impact future decisions. Here, our region R has a number of landmarks (numLandmarks) which are distributed through the space. The cellular space is of size N by M and a cell can have at most one landmark assigned to it. Each day after the group decides on a direction to move based upon the memories associated with the landmarks currently visible from their location (visibility).

Each individual effectively pools the satisfaction scores for the memories associated with the visible landmarks in each of the eight directions. Here the scores are represented by a preference scale from -5 to +5 where the + direction represents satisfaction and - dissatisfaction. The direction with the highest score is the direction of choice for an individual. That choice is then weighted by their status in the group. Each member then moves in the direction of their choice and is observed by the others. The group moves in the direction which achieves the highest consensus as observed by a mediator.

Group size can change based upon the extent to which individuals are fed. Individuals who have not gotten sufficient resources over a given period die and a group is removed when all of each individual have died. On the other hand if the group has been able to feed all of its members over a given period it can add a new individual up to a maximum group size. When it reaches that size it can fission into a second group.

3 Model Description

The **Band model** is an agent based model that simulates the foraging behavior of groups of hunter-gatherers using the vector voting method described above. The bands move in a rectangular space, looking for food. The size of the band can increase or decrease over time based on its success in acquiring resources. Fission or fusion of a band takes place when a maximum or minimum number of individuals is produced.

The model supports a variety of food distributions, agent characteristics, and foraging behaviors. Food distributions include completely random distributions, distributions based on mathematical

functions, and distributions that simulate a variable distribution based upon local conditions such as terrain, water supply, etc.

Each band member can form memories of their individual successes and failures that they can use to guide their future search for food. At the beginning of each model day, each individual evaluates these memories and selects a preferred direction of travel or vector. The members of a band are polled and the direction preferred by a majority of the members is selected according to the vector voting model given in the previous section.

The band then moves in the selected direction, collecting food as they go. At the end of the day the collected resources are distributed according to the consumption strategy used, each member evaluates how well it was fed, and associates that memory with one or more visible landmarks on the terrain. Several consumption strategies are supported here. They are fixed rank order, round-robin, equal sharing, neediest first, and satisfied first. Each will be described in more detail later.

During the execution of the model, detailed information is written to files for subsequent analysis. This information includes:

- Band and individual survival rates
- Individual satisfaction rates
- Range of movement of the band
- Distance between bands
- Longevity of bands
- Band size

These data are then analyzed to develop the graphs that accompany this report. The project is implemented using Swarm, a multi-agent modeling package developed at the Santa Fe Institute (www.sfi.edu)

3.1 The Basic Agent Model

The system models the activities of hunter-gatherers searching for food in a defined landscape, these constitute our agents here. The hunter-gatherers are organized into bands that travel together in search of food. Their search is guided by fixed landmarks that are distributed across the landscape. Individual members of the bands form memories of their past successes and failures in finding food. Each memory is associated with one or more landmarks that are nearby when the memory is formed. Each memory records the degree to which the individual was successful in obtaining enough food on the day that the memory is formed.

Each day, every band selects a direction of travel based on the memories of the individual members of the band. Bands can move basically in a straight line in any of 8 compass directions (N, S, E, W, NE, NW, SE, SW). The distance traveled is limited to a maximum number of squares in the landscape grid. A limit of 4 squares has been used for all trials used in this paper. Bands move in pseudo-parallel, one square at a time, in rotation among the bands. Each band continues to move in that direction until sufficient resources are acquired to feed all band

members, an object is encountered, or the maximum distance limitation (4 squares) is met. A band will alter its trajectory in order to avoid an obstacle. Here the obstacles are either static (the region boundaries) or dynamic (other bands). It is assumed here that two bands cannot occupy the same cellular space at the same time. If a band encounters an obstacle a new direction is selected, based on the same vector voting mechanism used at the beginning of the day, in order to avoid the obstacle.

At the beginning of the day, each band member reviews the memories associated with any landmarks that are currently visible and forms a weighted sum of memory scores for each possible direction of travel. Weighting is based on the interval that has elapsed since the memory was formed or reinforced and the distance to the landmark. Old memories eventually expire. The direction with the highest score becomes that individual's preferred direction of travel. The direction in which the band will travel is selected by summing up the preferred direction for each voting member. The preferred directions of all adult members are scored and the band will travel in the direction that receives the most votes. One constraint that is placed on the selected direction is that no band can reverse its direction of travel from the previous day. If the reverse direction is selected, the second choice is used. The band then travels together in the selected direction with its members collecting food as they go.

Several algorithms are implemented in order to regulate the distribution of the collected food among the members of the band as they collect food in each new cell. These distribution algorithms include round robin, equal sharing, fixed rank order, neediest first, and a satisfied first strategy. Movement for the day stops when the band has traversed the maximum number of squares or when all members of the band have consumed as much food as they can for the day. Each member of the band has a Minimum Daily Requirement for food. A provision is made in the model for an individual to consume more than one day's requirement. This permits an individual that has not been fully fed in the past to "catch up". It also permits individuals to "get ahead" so that they will survive subsequent food shortages. An individual's failure to obtain the MDR on a given day produces a cumulative deficit in nutrition. If the deficit exceeds a selected limit, the individual dies.

At the end of each day, each member of the band forms memories based on how much food they obtained during the day. These memories are associated with one or more landmarks that are visible from the location at the end of the day. Both the visibility of landmarks and the visual abilities of individuals are controlled by model parameters. Each individual selects a random direction and records the landmarks that are visible in that direction. An alternative strategy of using the nearest landmarks for all individuals failed to produce enough variability of experience to drive the voting model.

3.2 The Food Distribution Patterns

The pattern of food distributions are an important part of the agent's environment here. Initially we tried various mathematical distributions that were intended to produce gradients of food availability. For reference purposes, we also ran trials against a completely random distribution of food on a cell by cell basis. In a completely random distribution each cell is assigned a resource value between 0 and the maximum quantity allowed in the cell selected from a uniform

random distribution. Recently, we have settled on a "patchwork" distribution that is intended to simulate a semi-arid environment in which food supply varies over the entire space but is uniform within localities. Our implementation of this distribution ties each locality to a landmark located at the center of the local area. Regardless of the distribution, as a group moves through a cell it is able to remove resources from the cell. This amount is generated using a uniform random distribution between the current cell value and 0. After the group has moved on, the cell can "regrow" its resources in a linear fashion over time. The parameters for regrowth are provided at run time.

The patchwork distribution represents or attempts to emulate the attributes of a semi-arid environment. This distribution is generated by creating uniform areas of food availability around each landmark on the landscape, perhaps analogous to desert oases. This distribution is created according to the following procedure;

Landmarks are distributed randomly on the landscape

Each landmark is assigned a random food value between zero and the maximum permitted quantity of food in a cell.

An area of fixed dimensions around the landmark is populated with food at that value.

If the areas around two landmarks overlap, the food level will be set at the value of the last landmark processed.

The following image shows a patchwork distribution:

Figure 1. An example patchwork distribution of resources in the model

3.3 The Swarm Model Implementation

The simulation was written in objective C and runs within the Swarm simulation environment. The Swarm simulation environment provides a collection of software objects and associated

methods or algorithms (routines that manipulate these objects) to support the execution of our band model. One of the advantages of this approach is that the basic utilities that are in common to many agent based simulations are pre-written and we only need to supply the object-oriented code for the model. The fundamental swarm object within which our simulation runs is called the **observer space object**. This object controls the graphics interfaces, scheduling of agent activity, and the performance of basic model control functions such as experiment length, and run initialization. It provides a framework in which the behavior of the simulation can be controlled and observed, hence the name observer space object. Table 1 gives the attributes or variables associated with the observer object along with the algorithms that it uses to control the execution of our simulation model here.

Object attributes	
Attribute	Description and usage
Display Interval	Controls how often the GUI display is updated. Set to 1 for all trials.
Experiment Duration	Number of days that the model will run before terminating.
Schedule Objects	Swarm scheduling control objects
Display Objects	Swarm display control objects

Object algorithms	
Attribute	Description and usage
Create model	Create the model objects
Run model	Execute the model

Table 1. The Observer Space is a swarm object that supports the graphical interfaces, scheduling, and control functions for the model.

Running within the observer object is our model. The key object in our model is the model space object. The **Model Space** is a rectangular grid depicting the agent's environment onto which other model objects are mapped. Its attributes and algorithms are described in table 2. Individual bands are placed into cells in the model space as they move about the landscape. Other objects, such as Landmarks, and Food Cells are overlaid on the Model Space and displayed on the common interface provided by the observer object. The dimensions of the grid are set by a pair of parameters. For most trials, a 128 by 128 model space has been used. Practical considerations of the data analysis software preclude large dimensions at this time.

The band model object attributes contain statistics that describe overall model behavior such as the number of bands that are dead, the life span of a band, the number of elapsed days in the model among others. In addition there are attributes that point to a lists of the current bands, the individual agents that comprise them, the current landmarks, and resource cells respectively. These constitute the basic model objects. In subsequent sections we will discuss the attributes and algorithms associated with each. There are also pointers to files that will be used to retrieve model data and archive results. Finally, the model parameter pointer references the list of model parameters that can be set upon model initialization and govern the interaction of the model objects.

The algorithms for the model space object are in charge of getting the model parameters, initializing the model according to those parameters, updating the model statistics after each model event, and logging diagnostic information about model performance that can be useful in debugging the model.

Object attributes	
Attribute	Description and usage
Day Number	Counter of the current day in the model.
Number of Dead Bands	Current count of the number of dead bands
Number of bands that have died.	Count of the total number of bands that have died since the beginning of the model.
Sum of band age at death	Sum of the age of all dead bands at the time of their death. Used to calculate average mortality.
Average age of band at death	Average age of bands that have died or are still living.
List Food Spaces	Pointers to the Food Space Objects
List of Landmarks	Pointer to the list of landmarks.
File object pointer	Pointer to the file control object
Maximum distance	The calculate diagonal distance across the landscape
Model parameters	Shared elements that can be set at the start of the simulation run to control the operation of the model.

Model Parameters	
Parameter Name	Parameter Description
BandSize	maximum size of each band (number of members)
BandSplit	size at which band can split

BandStart	size of each band at the beginning of the run (number of members)
BaseMDReq	base minimum daily food requirement for an adult
BounceMode	Behavior mode when a band reaches the edge of the space or collides with another band 0 – reflex bounce 1 – vote on a new direction
CAAcceptanceInterval	Cultural Algorithm Acceptance Interval (days) this is the interval at which the CA component accesses the data in the model space
CAInfluenceInterval	Cultural Algorithm Influence Interval (days) this is the interval at which the CA component provides feedback to the model space
CAMode	Selects the CA algorithm to be used,
caption	Trial Caption
consumeMode	mode of consumption during foraging
daysAhead	Number of days of consumption that an individual can stockpile to recover from shortfalls or to get ahead
daysToDie	number of days without MDR before a guy dies
decayDays	number of days for a dead band to decay and disappear from the display until this interval expires, the square occupied by the band is blocked to other bands
diagBand	A band number to trigger diagnostic outputs that are limited to a selected band
diagnosticDest	destination for diagnostic outputs 1 => console 2 => log, 3 => both
diagnosticInterval	diagnostic interval in days, interval at which diagnostic outputs will be written
diagnosticMask	diagnostic mask, a bitmap selecting various classes of diagnostic outputs
flipMode	select a yes no parameter to be flipped for each trial
foodDistFactor	First computational factor for food distribution. Used differently by each mode. Not always used.
foodDistFactor2	Second computational factor for food distribution. Used differently by each mode. Not always used.
foodDistMode	food distribution function
foodDistRange	food distribution range in squares usage varies by algorithm currently used only for mode 6, patchwork around Landmarks to control the size of the patches
foodMaxValue	The maximum quantity of food that can exist in a single cell
forageMax	number of squares to forage in Mode 1

forageMode	forage mode 0=en mass while traveling 1=individual after traveling (unimplemented)
lmDistMode	landmark distribution mode
lmPerMemory	controls how many landmarks are attached to a memory when it is formed
logDataInterval	interval to write to data log (days)
memDepth	memory depth in days, number of days after a memory is formed before it is forgotten
memMode	Memory formation mode
numBands	number of bands to generate
numLandmarks	number of landmarks to generate
quitAfter	Terminate the mode after this many steps. Results in program failure. Superseded by batch mode operation.
randomDays	number of days of random movement before using memory (during this interval, bands do not starve)
regenRate	rate of food regeneration per day (≤ 1.0)
reincarnateDays	number of days before a dead band is reincarnated
reproduceDays	Number of days where the band is fully fed before it can add a member.
searchMode	search mode
seedProb	probability of food in a cell (random distribution) also controls the minimum amount of food not currently used in other modes
starveMode	Mode for determining starvation
stepsPerDay	maximum number of steps to move in one day
stopEvery	interval (days) at which the model will pause
trialName	file name prefix for the trial (yyymmdd_hhmmss) this is not specified externally, but is generated and exported at run time
visibility	default landmark visibility in squares, for how many squares is a landmark visible
vision	default vision in squares, how many squares can a Guy see a landmark
worldXSize	X dimension of the model space
worldYSize	Y dimension of the model space
ZoomFactor	swarm zoom factor, 0 = automatic 1-

Object algorithms	
Attribute	Description and usage
Get methods	Obtain model parameters and control variables
Set methods	Set model parameters and control variables
Diagnostic methods	Log diagnostic information about model execution
Tracking methods	Maintain global information on model execution, such as number of living bands, etc.

Table 2. The Band Model space object attributes and associated algorithms

Now each of the model objects that interact within the grid world will be described. The basic objects are: **the food space cells**, **the landmarks**, and **the bands**. The bands are composed of individual **member agents** and each member agent has a list of **memories**. We will now describe each of these objects in turn starting with the top level model objects.

The **Food Space** is a rectangular grid that overlays the Model Space. Each cell in the food space contains a quantity of food that can be consumed. Two supplemental food spaces are defined to support variation in the food supply. The first of these contains the original values calculated when the Food Space was populated. This is used to control the re-growth of food after it has been consumed. The second is used to support seasonal variation of the food supply.

Object attributes	
Attribute	Description and usage
Current food values	Array containing the amount of food available in each cell of the landscape.
Maximum food values	Array containing the permitted maximum amount of food for each cell of the landscape.

Object algorithms	
Algorithm	Description and usage
Seed food space	A group of methods that seed the food space according to the selected distribution function
Regenerate	Grow more food to make up for the amount of food consumed. Executed daily.

Vary food	Change the available food according to a seasonal cycle.
Get methods	Obtain model parameters and control variables
Set methods	Set model parameters and control variables
Diagnostic methods	Log diagnostic information about model execution

Table 3. The object attributes and the algorithms for the food space object. Its attributes include the current and maximum food values for all grid cells.

Just as the food cells are overlaid onto the model grid, so are the landmarks. **Landmarks** are randomly distributed throughout the landscape. They are commonly observed landscape features that can be used as reference points in the decision making of the bands. While landmarks can be randomly placed within the landscape, certain landmarks were placed in certain grid positions to ensure that the entire region was potentially exploited by the bands. For example, a Landmark is placed in each corner square of the landscape. This choice was based on early observation that bands could not navigate into the corners of the space unless there was a Landmark towards which they could move.

Landmarks are used to support memory formation and band navigation. Each memory references one or more landmarks that are visible from the location where the memory was formed. All navigational choices made by individuals are made on the basis of moving towards or away from a landmark.

Each landmark is an object whose state is described in terms of its position on the grid, the maximum distance from which it can be viewed, along with a list of memory scores that have been produced by individuals within view of the landmark. The basic algorithms for landmarks are their distribution (randomization), and the collection of statistics about their use in decision making. Currently landmarks are viewed as static objects so degradation or improvement in their visualization appears over time.

Object attributes	
Attribute	Description and usage
Position	X and Y coordinates of the landmark
Visibility	Distance at which the landmark is visible
Landmark scores	Information about the quality of memories associated with the landmark.

Object algorithms	
Attribute	Description and usage
Distribute landmarks	Distribute the landmarks more or less randomly on the space.
Landmark statistics	A series of methods that maintain current and prior history on landmark performance in memory searches.

Table 4. The object attributes and algorithms for the Landmark objects.

While the positions of both food cell and landmarks do not change during the course of the simulation, the bands are able to move about in search of food. **Bands** are groups of individual hunter-gatherer agents. The members of a band move and forage together within a cell. At the beginning of a simulation run, bands are placed at random on the landscape. Since the carrying capacity of the environment can be estimated, the number of bands used will influence the selective pressure on the decision making process here. In all of the runs described here, more individuals are initially present than can be supported by the environment. This was done in order to assess the robustness of the vector voting model under duress.

Each band starts with a specified number of members. This number can be reduced by the death of members or increased by the addition of new members. Both the addition and deletion of members results from the foraging activity. If the group fails to meet the MDR for some of its members over a period of time, deaths can result. If all members of a band die, the band is removed from the model. New members can be added to a band whenever all members of the band have received their minimum daily requirement for a specified number of days. Only one member is added, and the interval starts over. When the band size reaches a maximum, fission can take place where the new band is placed in the location of a deceased band.

Since band decision making is at the heart of the model, the band object is the most complex model object here. Table 5 gives its attributes and its algorithms. A number of band attributes relate to its current status in terms of creation, number of members and a pointer to a list of its members, current direction of movement, and number of members fed among others. Random days is an attribute that determines how many days the group will move at random before decision making via vector voting begins. The random movement simulates the discovery of the new territory by the band and allows them to record memories about their experience which serve as the fuel for the decision making process. Random days is an attribute that determines how many days they forage randomly until decision making begins. For the completely random model, the number of days is equal to that of the simulation length. The band algorithms include methods for initializing a new band, starting a day, finishing a day, updating its members daily information among others.

Band object attributes	
Attribute	Description and usage
Size	The maximum permitted size of the band.
Member list	Points to the guys in the band
Random days	The number of days of random motion to be performed before using the search algorithm. Zero for all recent trials.
Total Daily Requirement	The total amount of food required by the band on a single day
Band dead	An indicator that the band has died
Band decayed	An indicator that the band has been dead long enough to be removed from the display and also long enough to be reincarnated.
Day created	The model day on which the band was create or reincarnated
Direction	The current direction of movement for the band
Days fed	The number of days during which the all members of the band have received their MDR.
Have eaten	Indicator of whether the members of the band received the MDR today
Number dead	The number of members in the band who are currently not alive.
Number in and	The number of members in the band who are currently alive
Consumption order controls	Controls the order in which members are fed.
Contact information	Counters of the number of times the band collided with or was next to another band
Day band died	The day on which the band died. Used to control reincarnation of bands.
Range date	Deflections in the X and Y axis during a measurement period.

Band object algorithms	
Algorithm	Description and usage
Get methods	Obtain model parameters and control variables

Set methods	Set model parameters and control variables
Diagnostic methods	Log diagnostic information about model execution
Maintain count of alive and dead	Methods to maintain the current living population of the band
Select direction	Method to obtain and tally votes from the band members
Step	Method to perform one step's processing for the band, including movement and consumption
Start day	Method to control beginning of day processing, including selection of direction
End day	Method to control end of day processing, including memory formation by band members
Reincarnate	Reincarnate a band that has previously died.
Forage	Consume food at the end of a day's movement (unimplemented future function.)
Maintain movement and contact statistics	Group of methods to maintain statistics on range of movement and contact with other bands.
Reproduce	Method to add a member to a band during good times.

Table 5. Band object attributes and methods. The band object is the most complex of the model objects. In particular there are a number of algorithms associated with its behavior.

Agents are individual members of a band. They are the second most complex model objects.

Each **member object** forms memories based on how much food it receives on a given day. A number of variables describe the state of an agent including their age and gender, the MDR for their category, where they are located, the landmarks that are visible from their current location, the amount of food they have gotten today, the memories that they have of their experiences, and how they have voted in terms of the bands decision making. The algorithms for an individual agent include making memories, consuming food, starting the day, ending the day, their vote in the foraging decision, and other algorithms to compute agent statistics. The description of the agent object attributes and algorithms are given in table 6 below.

Object attributes	
Attribute	Description and usage
Adult	Flag indicating whether the member is and adult of a child
Gender	Flag indicating whether the member is male of female

MDR	Minimum Daily Requirement of food
Memory list	List of memories
Vision	Number of square in the landscape that the individual can see a landmark. Not used in any current models.
Food consumed today	Amount of food consumed today
Days without food	Number of days during which the member has not received the MDR
Dead	Indicates whether the individual is dead
Food deficit	Cumulative shortfall of consumption against MDR
Number of Memories	Current number of memory entries for this individual. Used to gather model statistics
Last vote	Holds the last direction the member voted for. Use to calculate dissatisfaction.
Total dissatisfaction	Cumulative total of dissatisfaction. Used to determine consumption order.

Object algorithms	
Attribute	Description and usage
Get methods	Obtain model parameters and control variables
Set methods	Set model parameters and control variables
Diagnostic methods	Log diagnostic information about model execution
Vote for a direction	Decide which way the member wants to travel
Make a memory	Create a memory based on current location and today's consumption experience.
Start of day	Perform start of day processing, including clearing of consumption counters
End of day	Perform end of day processing, including calculation of satisfaction
Consume food	Consume food up to the MDR
Consume more food	Consume food beyond the MDR if it is available, up to the

	permitted multiplier
Forage	Look for food at the end of a day's movement (unimplemented future function)
Food needed	Calculate the current need for food. Used to control consumption order
Check whether fed	Compare the amount consumed with the MDR
Reproduce	Change status from dead to living, resetting all controls

Table 6. The attributes for the agent objects and their algorithms.

Just as band objects are contained in the model grid, and agent objects make up the bands, each agent has a list of **memories** that guides their decision making. At the end of each day's movement, every member forms a memory. The content of this memory is a score that indicates how well the individual was fed on that day along with the landmarks associated with the memory by the individual (good), the x and y location in which the memory was formed, and the list of landmarks associated with the memory by the individual. The basic algorithms for this object are the addition and deletion of memories. This constitutes the emulative learning component of the model. The description of the memory object attributes and algorithms are given in table 7.

Object attributes	
Attribute	Description and usage
Get methods	Obtain model parameters and control variables
Set methods	Set model parameters and control variables
Diagnostic methods	Log diagnostic information about model execution
Active indicator	Indicates whether the memory is active or expired
Directions	Direction of movement into and out of the square where the memory was formed (unimplemented future function)
Good	Score reflecting the food consumption associated with the memory -5 – obtained no food +5 – obtained as much extra food as was allowed.
Landmark list	List of landmarks associated with the memory. Used to select memories for navigation.
Position	X and Y position at which the memory is formed. This is

	maintained but is not used when interpreting a memory.
--	--

Object algorithms	
Attribute	Description and usage
Get methods	Obtain model parameters and control variables
Set methods	Set model parameters and control variables
Diagnostic methods	Log diagnostic information about model execution
Reincarnate	Clear memories as part of the band reincarnation process
Add a landmark	Associate a landmark with a memory

Table 7. A description of the memory object attributes and algorithms

This concludes the basic description of the objects used to support the Band simulation model in the swarm environment. In the following section we use the simulation model to ask various questions about the capabilities of the vector voting model when used in conjunction with emulative learning.

4 Experimental Results

The vector voting model augmented with emulative learning was applied to a variety of different environments, each with a different resource distribution patterns. The goals of these experiments are four-fold:

- To compare the model to a base line random walk through the environment.
- To observe any emergent patterns of foraging behavior that correspond to those exhibited in primate and hunter-gatherers groups.
- To observe the relative survivability of groups in terms of various cognitive and social parameters, e.g. the number of memories an individual can have.
- To observe the impact that resource sharing has on the performance of the vector voting model. That is, what forms of sharing are best able to support the vector voting decision making model are which make the model less robust.

While a number of experiments have been conducted we will summarize some of the results here. This section describes two sets of experiments that were performed during the initial stages of the project. The first set of experiments is intended to test the hypothesis that the vector voting strategy performs better than a random search for food in certain environments. In addition, we wanted to determine what specific patterns of behavior emerge when vector voting is used and how these patterns relate to those patterns observed within primate and human hunter-gatherers. The second set of experiments compares the effect that the sharing of resources among band

members has on the overall performance of the vector voting model as well on the specific patterns of foraging behavior that emerge. That is, which sharing paradigms are most supportive of the vector voting model, and which paradigms are not.

In general, a set of 10 trials has been used for each of the two experiments. For each trial, a pair of simulations was run. The same random number seed was used for each of the trial pair. For example, for the first set of experiments the trial pair will be a vector voting model and a random walk model. The results of each series are averaged to produce a result set for analysis. The food and landmark distributions are held constant for a group of trials so that scoring of landmarks and interpretation of patterns of movement can be compared.

4.1 Random Walk versus the Vector Voting Model

A series of 10 trials was run where every band performed a random search for food. An equivalent set of trials was run against the same food and landmark distributions using the vector voting model to regulate group decision making. All simulations are run using the patchwork food distribution and the set of model parameters given below.

Figure 2. An example of the patchwork distribution used in the runs

Parameter Name	Parameter Description	Parameter Value 1	Parameter Value Description 1	Parameter Value 2	Parameter Value Description 2	Mismatch
bandSize	maximum size of each band (number of members)	6		6		
bandSplit	size at which band can split	0		0		
bandStart	size of each band at the beginning of the run (number of members)	3		3		
baseMDReq	base minimum daily food requirement for an adult	1500		1500		
beliefOption	Belief Space Option - unimplemented	0		0		
bounceMode	Behavior mode when a band reaches the edge of the space or collides with another band	1	make new decision on bounce	1	make new decision on bounce	
CAAcceptanceInterval	Cultural Algorithm Acceptance Interval (days) this is the interval at which the CA component accesses the data in the model space	10		10		
CAInfluenceInterval	Cultural Algorithm Influence Interval (days) this is the interval at which the CA component provides feedback to the model space	100		100		
CAMode	Selects the CA algorithm to be used,	1	basic landmark history	1	basic landmark history	
caption	Trial Caption	Memory Based Search		Random Search		YES
consumeMode	mode of consumption during foraging	0	fixed order	0	fixed order	
daysAhead	Number of days of consumption that an	2		2		

	individual can stockpile to recover from shortfalls or to get ahead					
daysPerYear	Number of days per year for seasonal variation	0		0		
daysToDie	number of days without MDR before a guy dies	7		7		
decayDays	number of days for a dead band to decay and disappear from the display until this interval expires, the square occupied by the band is blocked to other bands	7		7		
diagBand	A band number to trigger diagnostic outputs that are limited to a selected band	0		0		
diagLM	Diagnostic Landmark Number	0		0		
diagnosticDest	destination for diagnostic outputs 1 => console 2 => log, 3 => both	0		0		
diagnosticInterval	diagnostic interval in days, interval at which diagnostic outputs will be written	10		10		
diagnosticMask	diagnostic mask, a bitmap selecting various classes of diagnostic outputs	0		0		
flipMode	select a yes no parameter to be flipped for each trial	0	No Parameter Flipping	0	No Parameter Flipping	
foodDistFactor	First computational factor for food distribution. Used differently by each mode. Not always	0.5		0.5		

	used.					
foodDistFactor2	Second computational factor for food distribution. Used differently by each mode. Not always used.	0.5		0.5		
foodDistMode	food distribution function	6	patchwork around landmarks	6	patchwork around landmarks	
foodDistRange	food distribution range in squares usage varies by algorithm currently used only for mode 6, patchwork around Landmarks to control the size of the patches	12		12		
foodMaxValue	The maximum quantity of food that can exist in a single cell	16384		16384		
foodVarFactor1	Food variation factor 1	0		0		
foodVarFactor2	Food variation factor 2	0		0		
foodVarMode	Vood Variation Mode	0		0		
forageMax	number of squares to forage in Mode 1	0		0		
forageMode	forage mode 0=en mass while traveling 1=individual after traveling (unimplemented)	0		0		
goodMode	Mode for calculating good scores	0		0		
lmDistMode	landmark distribution mode	0	random (seeded corners)	0	random (seeded corners)	

ImPerMemory	controls how many landmarks are attached to a memory when it is formed	2		2		
logDataInterval	interval to write to data log (days)	0		0		
memDepth	memory depth in days, number of days after a memory is formed before it is forgotten	64		64		
memMode	Memory formation mode	0	use n closest landmarks in any direction	0	use n closest landmarks in any direction	
numBands	number of bands to generate	128		128		
numLandmarks	number of landmarks to generate	128		128		
quitAfter	Terminate the mode after this many steps. Results in program failure. Superseded by batch mode operation.	0		0		
randomDays	number of days of random movement before using memory (during this interval, bands do not starve)	0		0		
regenRate	rate of food regeneration per day (≤ 1.0)	0.05		0.05		
reincarnateDays	number of days before a dead band is reincarnated	9999		9999		
reproduceDays	Number of days where the band is fully fed before it can add a member.	10		10		
searchMode	search mode	1	memory based vector voting	0	random	YES

seedProb	probability of food in a cell (random distribution) also controls the minimum amount of food not currently used in other modes	1		1		
starveMode	Mode for determining starvation	1	deficit > MDR * days to die	1	deficit > MDR * days to die	
stepsPerDay	maximum number of steps to move in one day	4		4		
stopEvery	interval (days) at which the model will pause	100		100		
trialName	file name prefix for the trial (yyyymmdd_hhmmss) this is not specified externally, but is generated and exported at run time	20010213_201544		20010213_200222		YES
visibility	default landmark visibility in squares, for how many squares is a landmark visible	32		32		
vision	default vision in squares, how many squares can a Guy see a landmark	32		32		
voteMode	Voting mode (unimplemented)	0		0		
worldXSize	X dimension of the model space	128		128		
worldYSize	Y dimension of the model space	128		128		
zoomFactor	swarm zoom factor, 0 = automatic	0		0		

Table 8. The run parameters for the experiments used here

As we might expect, a memory directed search performs significantly better than random movement in almost all food landscapes. The one exception is that if the food distribution is

completely randomized, there is no advantage to the memory directed search. However, in all of the examples given here, the global distribution of resources is random, but the local distribution of resources is patterned. The question is whether the vector voting model can outperform the random walk model even when there is just local patterning. If it can, then it should do even better when region-level patterns are present. The following diagrams compare metrics averaged over the 10 trials between the random walk (random search) and vector voting search (memory based search) models for the locally patterned patchwork examples.

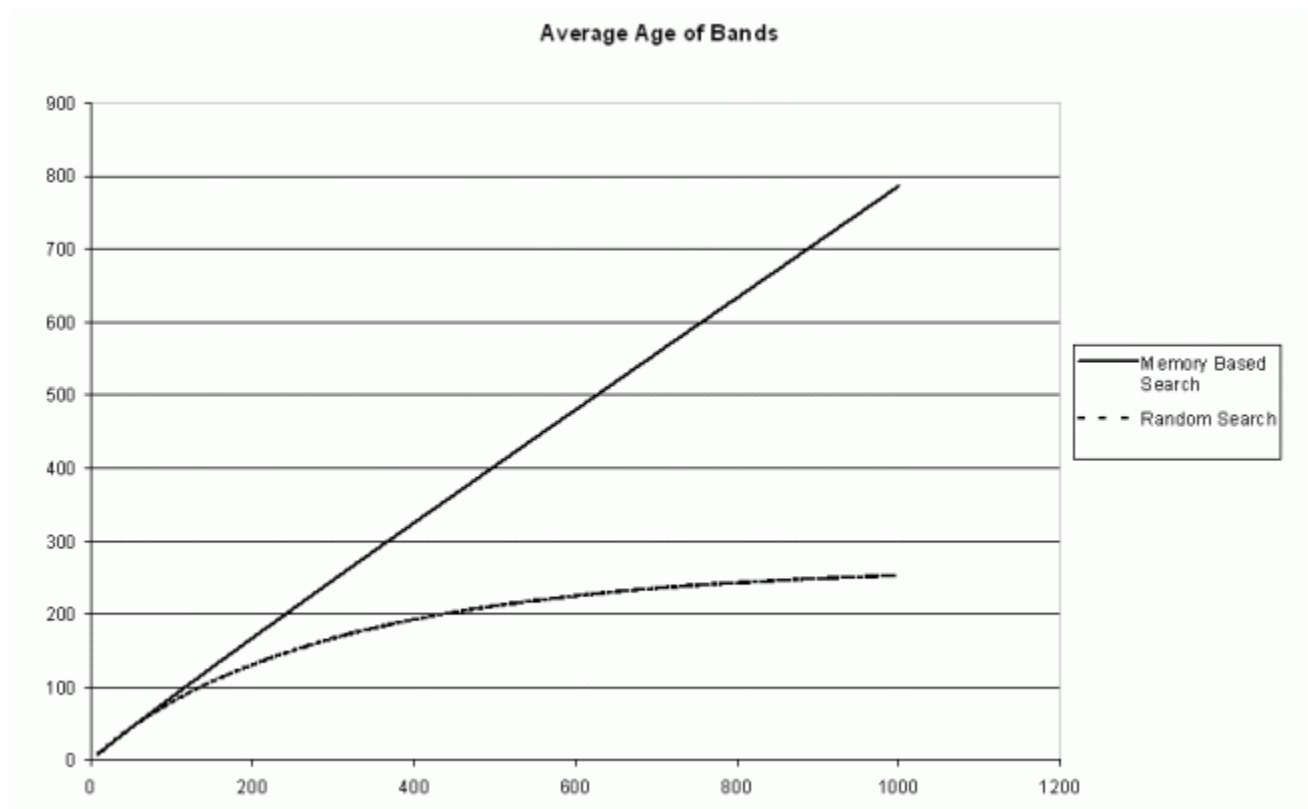

Figure 3. The average age of model bands over a 1200 day simulation for the vector voting (memory based) and random walk (random search) models

Figure 3 shows the average survival age of bands during the execution of the model. This calculation is an average of the age of bands at the time they died as well as the age of each surviving band. The curve for the random model flattens out over time indicating that the age of current bands is contributing less and less to the sum. In other words, the number of surviving band is approaching 0. On the other hand, the age of the surviving bands for the vector voting model is producing a relatively constant increment to the sum over the 1000 model days. That is, a consistent percentage of bands are surviving year after year.

Figure 4 shows the number of individuals getting fed over all bands for each year. The carrying capacity for the environment is approximately 300 individuals. Our initial population was 384, slightly over the maximum amount that we estimated could be supported by the environment on a continuous basis. So, it provides some initial selective pressure on the bands. Initially, the

foraging is random in order to gather information for use in decision making. Since all of the food cells are at the maximum at onset the groups are able to increase the number of individuals getting their maximum daily requirements. However, once foraging has started to deplete the resources, the number of individuals getting fed tends to converge to around 200 for the vector voting model, about 100 less than the total carrying capacity. By the addition of more landmarks and the proper selection of the sharing algorithm, the system can plateau at even higher levels, approaching 300 as the maximum plateau. The number of individuals fed by the random walk model continues to decrease approaches 0 as an equilibrium point. Although it is clear that the environment can support more than that, the system has not been able to acquire sufficient information to exploit those patterns.

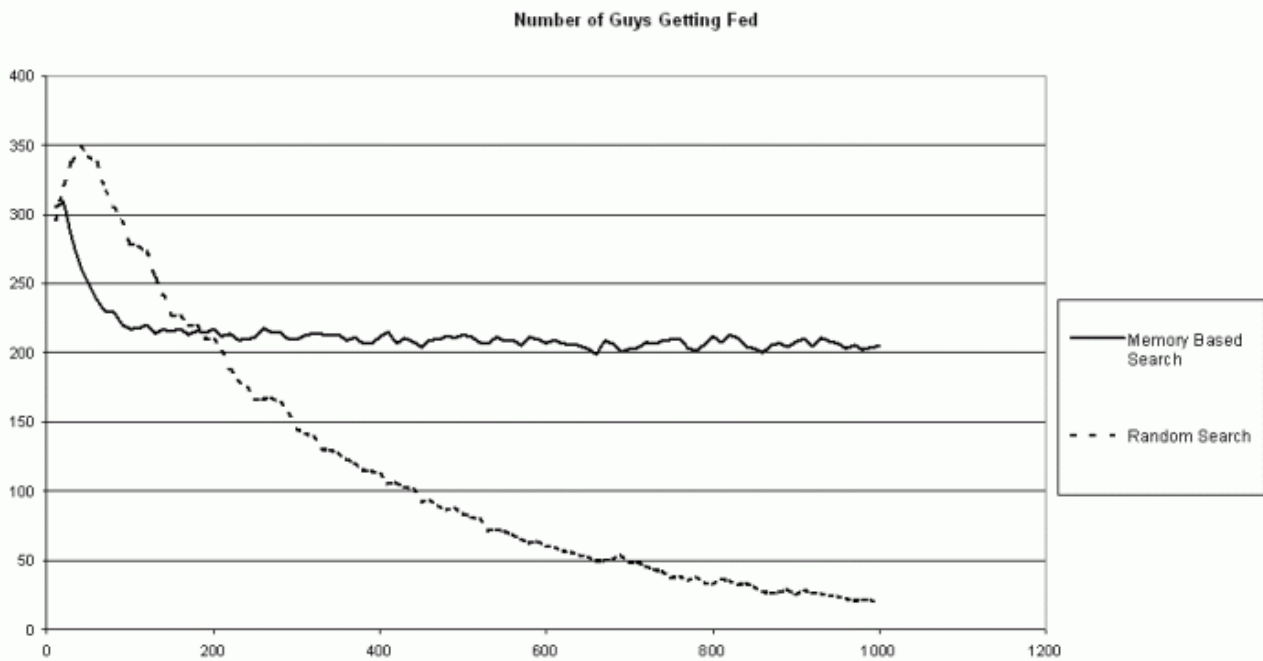

Figure 4. Average number of band members getting fed in the region over 10 runs each for the vector voting and random walk models.

Figure 5 shows the number of band members that were alive on each day of the model execution. Notice that in both cases the numbers of individuals alive exceeds the number of individuals getting fed. For the vector voting model, this number tends to plateau out around 260 here, about 40 less than the carrying capacity. The key is that in any one point in time not all individuals are getting fed, but enough get fed frequently enough in order to allow the overall population to plateau at a higher level than that for those getting fed. The random model again approaches an equilibrium of 0 as the difference between the number of those getting fed and those alive becomes 0 as does the population.

Figure 5. The average number of individuals alive for each model year in the vector voting (memory based) and random walk (search) models for 1200 days.

The results above demonstrate the effectiveness of the memory based search algorithm in finding food in a harsh but consistent environment. The vector voting model is able to exploit sufficient local patterning of resources in order to produce a suggested equilibrium population of around 260, just under carrying capacity. All of the bands without any memory based decision making died out even though the environment was able to support a proportion of them.

4.2 The Effect of Resource Sharing On Vector Voting Model Performance

In this section we perform a series of 10 trials each using 5 different resource distribution models. These were:

Fixed Order - the members of a band are fed in the same order on each day. The first member eats as much as it needs to reach the MDR before the second member eats anything, etc.

Equal shares - each member of a band receives a portion of the food that is based on the individuals MDR. Each member with the same MDR gets the same amount of the collected resources.

Neediest first - the members of the band are fed in an order based on their food deficit. The member with the largest deficit eats first, etc.

Satisfied first - the members of the band are fed in an order based on their satisfaction with the direction of travel. Those who voted for the selected direction eat first. Those who voted for adjacent directions eat next, etc.

Round Robin - the members of the band are fed in sequence, starting with a different member in rotation on each successive day.

Various success metrics were evaluated for each set. These include:

Band longevity - the average age of a band at the point where it died (all members are dead) or at the point in the simulation where the measurement was taken if the band is alive (has at least one living member). This is charted over the duration of the simulation.

Bands that are dead - the number of bands where all members of the band are currently dead. In the absence of reincarnation processing, this is equivalent to the number of bands that have died up to the point when the measurement was taken. This is charted over the duration of the simulation.

Bands that were fed - the number of bands in which all members of the band received the MDR on the day of the measurement. This is charted over the duration of the simulation.

Guys that were fed - the number of individual members of the band who received the MDR on the day of the measurement. This is charted over the duration of the simulation.

Five sets of 10 trials each were run covering 5 food distribution modes with each mode coded as follows:

- Mode 0 - Band members are fed in a fixed order on each turn.
- Mode 1 - Band members receive equal shares of the food on each turn.
- Mode 2 - The band members with the largest food deficit are fed first on each turn.
- Mode 3 - The band members who wanted to travel in the chosen direction are fed first on each turn.
- Mode 4 - The band members are fed in a fixed order, starting with a different member in rotation on each turn.

All simulations were run using a memory based search with a patchwork food distribution.

Figure 6 shows the rate of survival for each of the five distribution modes. The vertical axis is the number of surviving band members and the horizontal axis is the day number.

One of the key things to note is that the performance of the vector voting model is markedly affected by how the resources are shared among the individuals in a band. This is due to the fact that there is no sharing of information among band members concerning the memories that brought about the decision of each. Thus, if individuals who are making bad choices are rewarded as much as those who are making good ones, it is likely that a member making a good choice will die and their memories will be lost to the group forever. Thus, both the round robin and equal sharing paradigms cause the number of individuals to be supported by vector voting models to converge to 0. This is equivalent to the random walk model. This is because the loss of key individuals is causing the decision making to behave in a random manner.

On the other hand, by rewarding the individuals who contributed to the winning decision we are rewarding the providers of key information and working to preserve the groups information that is stored at the individual level. Thus, satisfied first performs the best of the five, producing overall population levels approximately equal to the carrying capacity of the environment. In this case, vector voting exploits the local patterning of resources and satisfied first supports the retention of this information at the local level. "Survival of the fittest" in the case where there is no shared information between individuals means "survival of the group".

Fixed or rank order access to resources performs slightly less than the satisfied first paradigm, but not much less. It is also easier to enforce since one doesn't have to poll the members and decide who did what, where and when. Thus, fixed rank is a good fit with the vector voting model since it produces performance comparable to the satisfied first approach without the social overhead.

The neediest first paradigm is midway between the two groups. Once the population size is significantly below carrying capacity, the vector voting model allows sufficient exploitation of the environment to allow most individuals to be fed. Thus, the randomness that is introduced into the decision-making process is balanced out by the individuals that are helped through the process. Notice that if the group is allowed to share their detailed memories via language, the relative performance of this more altruistic strategy will improve.

Figure 6. The average number of individuals in the population over 10 runs for each of the 5 food distribution modes

5 Conclusions

In this paper we augmented the vector voting model of consensus-based decision-making in primate groups with emulative learning. Emulative learning was the basic form for cultural transmission used here. Extensive runs of this model suggest that the consensus based approach based upon icon memories was sufficient to produce regional populations that approximate the carrying capacity of a randomized, resource scarce environment when certain resources sharing strategies as used to distribute resources among a band's members. Thus, while the vector voting model cannot theoretically make the best choice all of the time, coupled with feedback in the form of emulative learning it is able to effectively optimize the number of individuals living in a relatively harsh class of environments, semi-arid environments here. The key is that although the environment exhibits local dynamics, it does not display local dynamics at this point. Therefore, a decision-making approach, such as the vector voting paradigm, that efficiently exploits local dynamics is sufficient to produce an optimum population size here relative to carrying capacity.

The vector voting model, while exploiting local patterns effectively, is very sensitive to the resource distribution system used. This is because individual knowledge is not shared. This means that if resources produced by the vector voting approach are shared without any consideration of the individuals who made the decisions in the first place, the individuals and their attendant information can be lost introducing randomness into the process and ultimately generating performance that can be the same as a random walk. Thus survival of the fittest is synonymous with survival of the group when information is not sharable.

Also, there are two resource sharing strategies, satisfied first and rank order, that tend to produce the results that are closest to the carrying capacity. While the satisfied first approach is the most precise way to reward the individual responsible for a groups success, and in turn preserving the information that they used, it requires a certain amount of overhead to manage and enforce. A fixed or rank ordering of access to resources produces results that are slightly, but not much lower, and with less overhead in terms of how to determine allocation.

The next step in our project is to implement the Cultural Algorithm paradigm which allows the individuals to pool their memories. Theoretically, this sharing of information will allow the group to make regional decisions about certain predicates more reliably than in the vector voting model. In particular, the pooling of information via a belief space will allow the group to decide on predicates that are not tied to particular locations, e.g. norms of behavior, within the environment. These are called position invariant predicates. Being able to do this makes imitative learning, a form of learning largely unique to the human species, possible [5]. Both activities are influenced by the structure of the language used to perform the pooling and within which the learned information can be articulated. This will be the subject of a subsequent paper. Also, it will be of interest to see how the introduction of shared information impacts the relative utility of the resource distribution modes. That is, will equal access to knowledge within the group imply that equal access to resources will provide better support for group decision making than it currently does in a vector voting environment.

LANGUAGE CHANGE AS EVOLUTION: LOOKING FOR LINGUISTIC “GENES”

Vienna English Working Paper

By
Nikolaus Ritt

I would be extremely grateful for comments and criticism. Please send me an eMail.

0.0. Prolegomena

This paper argues for the view that language change and acquisition represent evolutionary processes in a sense that we nowadays tend to associate with Darwinism. This view is not exactly new, but has never really established itself within the community of historical linguists. It goes back, at least, to August Schleicher, to whom we owe the notion of linguistic 'family trees' and who viewed languages as similar to organisms with life-cycles in the sense that they are first 'born', then grow into fully-developed, or maximally complex 'adults', and may finally degenerate, lose their complexity and possibly 'die'. His conception of 'evolution' was essentially pre-Darwinian, though, and his application of the concepts to linguistic study highly metaphorical. Since Saussure and the formalist linguistic tradition he more or less established were opposed to the borrowing of metaphors from other sciences on grounds of principle, it is no big surprise that approaches like Schleicher's ceased to be taken seriously. Evolutionary concepts only sneaked back in disguise, so to speak, into linguistics via the functionalist approaches developed by Jakobson and the Prague School. There, language change was regarded as functional, 'goal directed' and, one could say, 'adaptive' in a sense similar to the one the term has in biology. However, the functionalists didn't explicitly base their explanations on a theoretical framework that could be called truly evolutionary in the Darwinian sense - probably because they were too cautious themselves to borrow metaphors which, they must have felt, belonged essentially to a different science and had no place in theirs. Retrospectively, I feel that by being so cautious, they made things unnecessarily difficult for themselves, as it may have been due to the very lack of an explicitly evolutionary framework, that their approaches to language change were vulnerable to attacks from structuralists (such as Lass, see for example 1980: 64ff.) for being teleological and unable to offer truly causal explanations. - Whatever the exact reasons for the development may have been, however, it is apt to say that nowadays, as April Macmahon puts it, „Evolution [...] has become a 'dirty word' in modern linguistic theory" (1994: 314).

It is little surprising, therefore, that more recent attempts at dealing with linguistic phenomena from an explicitly evolutionary point-of-view have originated at the margins, or even outside the linguistic community itself. Here is a survey of books and articles that I have found particularly inspiring.

First, I would like to mention Cavalli-Sforza and Feldman's, and Lumsden and Wilson's volumes on cultural evolution. Both include linguistic evolution without giving the latter much space in their arguments or presenting any specifically linguistic cases, though. Similarly, Richard Dawkins' (1982 and 1989) proposal that cultural evolution might be based on the existence of 'mental replicators', which he calls 'memes', seems to be straightforwardly applicable to

language evolution, while Dawkins himself does not develop his arguments in that direction. Interesting comments on Dawkins' proposal as well as on the frameworks developed by the other authors just mentioned can be found in Maynard-Smith (1989).

More recently, a group of scientists based at the Sta. Fe Institute have been developing an elaborate theory of 'Complex Adaptive Systems', which presents itself as a metatheory for the study of a large range of phenomena that display 'adaptive' behaviour and which are difficult to deal with on the basis of classical scientific approaches. These include national economies, immune systems, artificial intelligence, cognitive development and also, quite explicitly, language evolution. Due to the bad reputation which 'evolution' seems to have within the linguistic community, however, the workshop on the evolution of human languages, which the Institute organised in 1991, has not led to the establishment of a permanent research group.

While the failure of the Sta. Fe initiative shows how alien evolutionary concepts might still be to the community of mainstream linguists, contemporary cognitive psychology seems to be adopting evolutionism more enthusiastically. This becomes particularly obvious in Henry Plotkin's recent volume 'Darwin Machines and the Nature of Knowledge', for example. Since the links between cognitive psychology and linguistics are getting continually stronger, however, it seems that before long the linguistic community will have to give up its established biases as well. In other words, I feel that there are quite good chances that evolutionary theory might, after a long period of neglect, find itself to become the majority paradigm in (historical) linguistics within the not-so distant future. Evolutionism is in the air, so to speak, and will soon manifest itself strongly. And I don't seem to be the only one who thinks so. Thus, I have recently kept running into or hearing of colleagues who openly admit to working on possible applications of evolutionary theory to linguistics, although publications are still missing. Among these colleagues are April Macmahon from Cambridge, Guy Cook from London, or Steve McGill from Exeter. Also, Robert de Beaugrande's forthcoming volume on Discourse Analysis adopts many notions from the theories developed at the Sta. Fe Institute.

Finally, I would like to refer to two papers by myself, namely forthc. (a) and (b), in which I have thrown much caution overboard and been as explicitly evolutionary as I dared.

But back to this paper, then. It introduces some of my personal ideas about evolutionary theory and its relation to language change, acquisition and use. It does so in an informal, associative manner without giving much heed to potential advantages of the advocated approach over other, more conventional ones. It is intended to stimulate the search for such advantages, which I feel can easily be found. The main reason why I am not presenting them in any detail here is that they deserve, in my mind, an elaborate discussion that would necessarily go beyond the scope of this contribution. So, if this paper succeeds in arousing some interest and the desire to play around with some of the concepts and perspectives that it develops, I shall be happy enough. Otherwise, I hope that the reader will at least find the mental gymnastics my attempts at reasoning will force her to perform refreshing and worth the time spent on reading all this.

0. Introduction

*Since 'tis Nature's law to change.
Constancy alone is strange.
John Wilmot. Earl of Rochester*

--- A dialogue between Strephon and Daphne

This motto opens the first chapter of Jean Aitchison's classic volume on language change (1991). A weird choice, isn't it? After all, the book is about language *change*, so why are we told that it's *constancy* that we should really worry about? OK, I'm sorry. Of course, this is just a cheap move of mine, and, of course, Jean Aitchison was just trying to tell us that language *change* was less strange and unnatural than one might be tempted to think as a novice to the subject. - But still, if one takes the motto seriously, one cannot help but wonder. Why is it, quite generally, that historical linguists have always focused their attention on instances of linguistic change, and have not found it worth the trouble to deal with those elements in the world's languages that have maintained their identities and shapes over longer periods of time? Why is it, to mention a concrete case, that people in our field have mostly been trying to explain why Middle English long /i:/ shows up as /aI/ in Modern English, while the fact that Middle English short /I/ is still short /I/ in many Modern English words has been taken more or less for granted? At least in the light of the Earl of Rochester's insightful remark, this is almost as strange as constancy itself. In this paper, I'll do what strikes me as the obvious, therefore, and approach language history via constancy rather than change.

So, why is it then that Middle English short /I/ is still short /I/ in many Modern English words? Good question. Or is it? In what sense can we say at all that the /I/ in items such as ModE *middle, it, children* is the same as the - assumed - /I/ in ME *middle, it, children*? Although it is typically assumed that the two are in some sense identical, even a little bit of reflection tells one that things are not so self-evident at all.

On the one hand, we could say of course that the two /I/s are, in some sense, counterparts, because they fulfil similar communicative functions: *middle, it* and *children* mean pretty much the same in Modern and in Middle English, so there is good reason to assume that the purposes for and the situations in which Modern English speakers will use the words are at least roughly comparable to those which Middle English speakers had in mind when they employed them. If, by the same rationale, we then also say that both Middle and Modern English speakers used /I/ to distinguish words such as *middle, it* or *children* from others, it follows that the role which Modern English /I/ plays within Modern English speech communities is indeed similar to the one which Middle English /I/ played within Middle English speech communities.

In order for the question why Middle English /I/ is still /I/ in Modern English to be meaningful, though, the mere observation that the two /I/s are communicative counterparts is not enough. What makes the relationship between Middle English and Modern English /I/ special is that the two do not only play similar roles but that, in some sense, there also exists a kind of genetic relationship between them. In some way, Modern English /I/ seems to be a distant offspring of Middle English /I/, and we feel that Modern English /I/ has not only inherited many of the jobs

of Middle English /I/ but is its direct descendant at the same time. It is both its communicative, or 'functional', and its genetic counterpart. When we want to know why 'Middle English /I/ is still /I/ in Modern English, we are therefore dealing with two questions rather than one. The first would be: how has Middle English /I/ managed to produce offspring that have survived over the centuries? And the second question would be: why and how have the offspring of /I/ managed to take over the communicative functions of their forebears? In the following I shall deal with each of these questions in turn.

Before I go on, however, I guess I owe you a little break to reflect on the course which my argument (or rather my loose associations) seems to have taken. Thus, you will have observed that at the beginning my paper seemed to be about a speech sound, a phoneme, something well defined, you may have remembered, as an element of 'langue' in the Saussurean sense, and now I have come to talk about /I/'s offspring and about /I/'s jobs - just as if I were talking about a person, a human being, or at least a living thing of some sort, capable of reproducing and of doing things. - Obviously, you will think, my discourse has become metaphorical, and whatever the rhetoric or didactic advantages of metaphors might be, you will be aware that one must not let oneself be carried away by them and that, in particular, one must not tacitly endow them with a technical sense, because that way one might wind up in a completely fictional world and solve merely fictional problems that have no bearing on the world out there and thus no truly scientific value.

1. Phonemes (and other constituents of natural languages, for that matter) as active replicators
So, what about /I/ and its offspring then? Is there a technical sense in which such a statement can be read? In what way, if at all, can phonemes be assumed to increase and multiply? This question may sound weird to anybody whose mind has been framed to think in the categories established within the linguistic community - I agree -, but might it not still pay to take it seriously if only to see what happens? How can phonemes be assumed to 'propagate' then? I guess the first type of answer that will probably spring to the mind of most of us is: 'through language acquisition.'

Children learn phonemes through listening to (more or less) grown-up speakers communicating. The general idea is that some part of the human brain works as a device for language acquisition, into which some of the more basic principles concerning the way human languages work are hard wired, so to speak, and which, when exposed to actual utterances will filter out and store in its more flexible components those pieces of information that a speaker needs to produce such linguistic utterances as are likely to serve her communicative needs in the community she grows up in. Those pieces of information will either be more like elements or more like rules/processes, but the distinction doesn't really matter here, because we are interested in /I/, and /I/ is most probably an element rather than a rule. In any case, when we think of /I/ as being learned by humans and stored within some part of their brains, the picture seems to emerge of /I/ as being transmitted passively, while the active agents in its replication seem to be the speakers. It would seem, therefore, that when trying to answer the question why Middle English /I/ is still /I/ in Modern English, we ought to focus our attention on speakers and rephrase our question as something like 'Why have English speakers over the generations successfully acquired /I/'

But is this necessarily so? In what way are speakers really more active than, say, phonemes in the replication of the latter? Obviously, speakers do not control language acquisition consciously

and actively. This has been a home truth ever since Saussure. They are not normally in a position to decide whether they like to acquire a particular phoneme, for example, or not. In this sense 'langue' is beyond the control of individual speakers. So, if we wanted to investigate the speakers' role in language acquisition/replication we wouldn't be talking about speakers as autonomous subjects freely determining their own actions, but we would be looking inside them and disregard their personal integrities, so to speak. What we'd be interested in would be the ways their auditive apparatuses and their articulatory organs work, and also, of course, the way in which these interact with their brains and the way in which linguistic elements and processes are mentally stored. (It is assumed here that language ultimately does have - even though it may not be reducible to - physical reality.) The speakers we would be looking at then, would look like a system of muscles, membranes, teeth, assemblies of nerve cells and other such elements - not much like individuals at all, really.

And where would our phoneme /I/ reside in this mass? Well, although there are as yet no ways of verifying this, there is in fact only one reasonably plausible possibility. It must be located within the central nervous system, i.e. the brain. Without knowing much about the way the brain handles information, most neurologists would subscribe to the notion that an element such as /I/ might be located within an assembly of nerve cells that are linked - however remotely or indirectly- to both articulatory and auditory organs. That assembly, which 'represents', or, actually, 'is' /I/ will be excited when it receives input in the form of sounds that are 'recognised' as /I/ or when other parts of the nervous system get excited in such a way that a realisation of /I/ is pronounced. Another way of putting this would be to say that, depending on the actual state of other relevant parts of the brain, the excitement, or 'firing', of a nerve cell assembly 'I/' will trigger either the firing of such other nerve cell assemblies as eventually amount to appropriate movement of the articulators, and/or the firing of such assemblies which 'encode' or 'are' word forms, morphemes, concepts or socially relevant information. A brain can thus be said to host an /I/ assembly, if there exists a set of nerve cells within it that get indeed excited more or less simultaneously when they receive electrochemical input under such conditions as specified above. The existence of /I/ is thus established when the channels through which electrochemical energy flows during a brain's activity come to be set up in such a way that an assembly of them fires in quasi-unison. The acquisition of /I/ can consequently be thought of as a process that results in the establishment of appropriate links among a set of relevant nerve cells.

During its lifetime, then, an /I/ assembly may be in either of two states: when it fires, it is 'on', when it doesn't, it's 'off'. Due to the fact that the /I/ assembly is linked to articulators it may then happen that the firing of /I/ causes the latter to perform a gesture 'expressing' /I/, typically the allophone [I]. During a lifetime, an /I/ assembly can thus be assumed to give rise to a relatively large number of [I]s, and the [I]s that can be observed in actual utterances can thus be thought of as consequences, or expressions of /I/ in a similar way as the phenotypic characteristics and some behaviour patterns of organisms can be regarded as consequences or 'expressions' of genes. It is exposition to such [I]s in appropriate contexts, then, that allows children to acquire /I/s, or that - to stay within the descriptive framework I have begun to sketch - causes such links between certain nerve cells to establish themselves within children's central nervous systems that may be looked at - from the linguist's point-of-view - as (a representation of) /I/s. Through their inherent ability to produce [I]s under appropriate conditions, /I/s can thus place new copies of themselves within other nervous systems. - Looked at from this perspective, then, an /I/ - or indeed any

phoneme - can be thought of as an entity capable of its own reproduction - a true active replicator and perfect mental counterpart of a gene, which expresses itself through creating organisms capable of spreading copies of the gene through reproduction. In the same way as the story of gene reproduction can be told without invoking organisms as central agents (they can be referred to as the `vehicles' or `interactors' of genes), the story of the life cycle of a phoneme such as /I/ can be told without referring to `speakers' as the primary agents in that process. For the life and reproduction of /I/s `speakers' constitute only the necessary environment and the necessary tools, they play no active role in it - and they cannot, normally, influence it.

The first part of our question can now be partly answered. Middle English /I/ has managed to pass its offspring down to Modern times, because it was turned on often enough in the right way to produce [I]s, which in turn placed new copies of /I/ in the brains of new generations of speakers.

Obviously, this is only a rough approximation to an answer, and raises a lot of questions in itself. In particular, it is obvious that a variety of further conditions must be met if the production of [I]s is really to engender new /I/s. Exposure to [I]s will only lead to the acquisition of /I/ if the [I]s form part of communicatively effective linguistic messages. I will turn to the question how those additional conditions will look within the framework I'm just sketching presently. I would like to do this; however, by taking up the second part of our initial question, namely why it is that Modern English /I/ still does many of the jobs that ME /I/ did? As it seems to me, this question is more closely related to the problem of the conditions under which /I/ will get acquired than might first be suspected.

What are those jobs I am talking about anyway? Let me give a few examples. Well, first of all, there is the primary function of /I/ as a phoneme, which is to distinguish the morphemes in which it occurs from one another. Secondly, there are the functions of making pronunciation and perception possible, which /I/ shares with all other elements and processes that `inhabit' human phonologies, of course. Finally, then, there are other potential functions which a phoneme such as /I/ may have, including morphological ones such as indicating a particular morphological environment, or social ones such as identifying the social adherence of a speaker, and probably many others as well. Now, how do these functions translate into the framework that I have been sketching so far? If phonemes are regarded as nerve cell assemblies, then - interestingly, but actually quite obviously - so can the so called functions of a phoneme. If recognition of /I/ is viewed as the firing of an assembly, it is equally plausible to assume that if /I/ and /t/ fire one after the other, this event will in turn excite an assembly {/It/} which will automatically excite assemblies for {3rd person} {neuter} and {singular}. Similarly, both articulation and perception crucially involve the excitement of nerve cells along certain `pathways'. Thus, the perceptibility as well as the pronouncability of /I/ result from /I/'s association with the respective neuronal pathways. In other words and quite generally speaking, then, /I/ fulfils its functions by virtue of its associations with other cell assemblies. In some cases, as in morpheme recognition or in articulation, the firing of /I/ will cause a firing of associated assemblies, while in others the firing of appropriate `function' assemblies will cause a firing of /I/. The fact that /I/ does certain jobs can thus be viewed, quite simply, as its occupying a certain designated place within a network of associated cell assemblies and standing in mutual triggering relationships with those. Viewed this way, however, the jobs which /I/ does are at the same time the clue to its very existence as an

assembly, since only through being triggered to fire in unison a set of nerve cells emerges as an identifiable assembly in its own right. A number of connected cells that never come to fire in unison are, by definition, no assembly in the sense that we have established above.

It seems to follow, then, that whether or not an /I/ will emerge as a stably connected nerve cell assembly within a particular brain depends on whether it gets excited sufficiently often by the assemblies in its environment - and this, incidentally, represents an answer to the question concerning the conditions under which the production of [I]s can be expected to create new copies of /I/. As we observed, it cannot be enough for some sets of cells to be excited through input from the sensory pathway, because in order for /I/ to be acquired, it is not enough to hear [I] sufficiently often. Rather, [I] must be received and 'interpreted' as part of a meaningful message. In terms of the model I am sketching here, then, this can only be done, if there exist the relevant other 'linguistic' cell assemblies in the mental environment of /I/

Of course, if the acquisition of any linguistic element depends on the presence of other elements, the notorious chicken-egg question seems to raise itself. It can be solved relatively easily, though, on the assumption of repeated boot-strapping as well as of auto-catalytic self-organisation processes. One only needs to assume a very tiny set of linguistic 'universals' to be hard-wired (or 'inherited'), so that these then provide the environment in which further linguistic elements can establish themselves: an assumption that is perfectly compatible, if not equivalent, to the well established notion of a genetically provided 'language acquisition device'. Whatever the detailed mechanisms behind the emergence of fully functional language systems, though, I feel that the picture that emerges from what has been said so far offers a rather cute re-interpretation of Saussure's view of language as a system 'ou tout se tient'. At the same time, the dependence of /I/ on the presence of certain other assemblies represents another beautiful analogy to DNA based evolution, where the evolutionary stability of genes also depends on the presence of other genes within the genome. In the same way - to give just one example - as an /I/ assembly makes sense only within a more or less complete system of other 'language assemblies', there can also not exist a gene for eye colour without the system of genes that manufacture the rest of the eye and the organism around the eye.

Another important aspect of the acquisition of such linguistic elements as the /I/ that this paper focuses on, is that they can be assumed to establish themselves within a new brain only, if their establishment and the activity it causes in associated assemblies gets 'rewarded' and thus 'reinforced'. In other words, the effects of an emerging assembly on its environment must be such that they feed back on the assembly by making its future firing more likely, so that the assembly acquires the necessary stability. 'Reward' and 'reinforcement' must ultimately come from neuronal activities whose effect is that they make people feel good, or, in other words, cause psychosomatic states which represent positive emotions and which are probably hardwired (i.e. genetically determined) into the nervous systems of human beings.) This is just a technical way of saying that the acquisition of appropriate linguistic cell assemblies is probably rewarded through the positive emotions that go along with successful communicative acts, or - in yet simpler terms - that a brain will acquire such elements as help its bearer to get himself across to and understand other members of the speech community. The acquisition of an /I/ phoneme can thus be viewed as just one series among the adaptive process that a brain goes through as it evolves towards a state in which it enables its owner to interact/communicate with her

environment in a sufficiently harmonious manner. At first, an assembly which eventually turns out as an /I/ will be just one of a larger set of many possible neuronal configurations a brain may assume. As its activity, that is its firing, turns out to have rewarding effects more often than the firing of other neuronal configurations, it will probably 'attract' more electrochemical energy and get fired more often than the latter. By virtue of that fact, then, it will establish itself as a stable assembly, while its competitors won't. The emergence of an /I/ assembly within an individual brain can thus be viewed as a process that involves chance variation among brain states and selection of some states over others. The relative fitness of the competing states is determined by the degree to which they affect positive 'emotional' responses, while the general 'tastes' of emotions have probably been shaped through selectional processes acting on the genetic level.

For /I/'s success as an active replicator, this means, that its capacity of producing [I]s is just one aspect determining the success of its replication. Producing [I]s will probably increase the number of times an assembly corresponding to /I/ gets excited within a new acquirer's brain but it cannot guarantee that new /I/'s stability. However, the very existence of 'adult' /I/'s in the speech community also increases the chances for the effects of a potential new /I/ to be 'rewarded' and thus greatly increases the chances of a new /I/'s stability. /I/ is thus an active replicator in two ways: it generates new /I/'s through emitting [I]s, and it breeds newly generated /I/'s by making its host (or: speaker) react to their effects in a way that gives the hosts of the new /I/'s the feeling of being 'understood' or having reached their communicative goals. So much for my view as to why Middle English /I/ is still /I/ in Modern English. /I/'s are still around in abundance in Modern English in environments similar to those in which Middle English /I/'s thrived, because the latter have managed to replicate themselves successfully through multiple generations of host brains.

2. Some reasons why I find it so attractive to view linguistic elements as replicators

What are the advantages, if any, of viewing phonemes as replicators? After all, it would have been equally possible to say that /I/ and its functions have been successfully acquired by successive generations of English speakers and that's why it is still around? And this sounds more familiar as well, doesn't it? It's much more easily digestible, doesn't demand mental gymnastics and seems to capture, basically, the same facts. So why take the trouble?

Well, I can think of a number of good reasons. Here I will present just two.

First, a statement to the effect that speakers have successfully acquired /I/'s over successive generations forces one to change perspectives, because phonemes and speakers belong to different ontological domains. Such a change is intellectually unsatisfactory, particularly in lack of a theory that makes the links between the two domains or levels explicit. Thus, saying that a speaker acquires a phoneme begs the question of how she actually does that, and in structural historical accounts this question is typically never taken up seriously or even answered, because speakers are treated as black boxes at best or even regarded as outside the domain of linguistic science proper. - The view sketched here, on the other hand, is perfectly explicit about the way in which language acquisition is supposed to work, while at the same time describing it exclusively from the point of view of the linguistic elements themselves. No recourse to notions such as that

of 'speakers' as agents in the story of linguistic evolution has to be taken. Speakers figure exclusively as the environments in which the replication of linguistic elements take place, and the story can remain a consistently 'linguistic' one.

Second, viewing linguistic elements as replicators opens the possibility of transferring to the study of linguistics many theoretical insights gained in other sciences that have for a longer period and more explicitly concerned themselves with the study of replicating systems and their evolution. First and foremost these include evolutionary biology, of course, but also other sciences applying generalised Darwinian frameworks, such as evolutionary cognitive psychology, artificial intelligence and particularly the study of systems that are capable of 'learning' on the basis of genetic algorithms, and so on.

In particular, the view that linguistic elements are replicators affords interesting aspects on questions relating to language change. Remember that I argued that the success of /I/'s replication depends, among other things, on whether a new brain can integrate /I/ meaningfully within the network of linguistic elements and processes that are emerging within it. One aspect of an emerging linguistic system or competence, is therefore, that it provides slots that need to be filled, and it is such a slot that an element /I/ needs to fill if it is to replicate successfully. It seems to be a characteristic of such slots that there is not only one way of filling them. As the evidence of linguistic variation and change show, it is possible and happens quite frequently that within one and the same speech community corresponding slots happen to be occupied by different elements within different brains. Thus, as a very trivial example, take the variation between /U/ and /A/ in English, where either of the two may occupy the slot provided by the context of such words as *hut*, *but*, *butter*, and so on. It can be said, therefore, that within the pool of linguistic elements which occupy brains of speakers of English, there is a competition between /U/ and /A/ for a certain defined slot, or that - with regard to that slot /U/ and /A/ are *alleles*, to borrow a term from genetics (where it refers to different genes that can occupy the same slot on a DNA strand and are thus competitors). Typically, such a competition for slots - on which any linguistic element depends for its existence - will take place in all instances of linguistic variation, so that variation itself can in fact be regarded as competition. Whenever variation leads to actual change, the cause for such an event must be that for some reason a new competitor for a given slot manages to place more copies of it there than its established rival. In the case of phonological elements, ease of perception and production will obviously play a great role there, in the case of other elements semiotic parameters determining the ease with which links between associated elements are established will probably play similar roles. At the same time, however, the fact that existing elements will tend to reward the establishment of what they 'recognise' as new copies of themselves will be a powerful barrier against the spread of new variants, and if a new variant is to establish itself successfully then it must have sufficient selective advantages over the established competitor. Such selective pressures which favour the spread of a new variant at the expense of an established one may among other things be due to changes in the environment of the slot, where environment includes both a slot's immediate systemic environment and the wider environment comprising the whole set-up of the speech community in which linguistic elements 'live'.

Also, the view of linguistic evolution as a story of items attempting, with varying success, to replicate themselves affords interesting perspectives on the notorious problems concerning the

actuation and the implementation of language change. Change is actuated under this view simply through undirected copying mistakes that occur in the replication process. It may have various reasons, some of them pretty straightforward, such as misarticulations and misunderstandings. More crucially, though, variation is already built into the copying process itself, since an item relies on an acquirer's brain to produce 'random' varieties of neuronal configurations among which the replicating item will reinforce those most similar to itself and thus make them stable. In other words, the processes by which linguistic elements get copied involves successive stages, during the first of which the average copying fidelity must necessarily be relatively low. The resulting variability of languages is thus a natural matter. - As far as the implementation of changes is concerned, then, it can be regarded as parallel to the implementation of mutational changes within the gene-pool of living species: it results from the relatively more successful replication of a new variant within the brains of a linguistic community.

Finally, this perspective makes one of the more puzzling aspects of language evolution easy to digest, namely the fact that - on the one hand - language changes often seem to be adaptive in the sense that they seem to make things easier for language users, while - on the other hand - the world's languages are full of elements and qualities that must count as clearly suboptimal with regard to those criteria that allow language change to be regarded as 'optimisation' in the first place. As the approach I have sketched here suggests, the items of which languages are made up do not primarily exist 'because of' the purposes they serve their speakers, but rather simply because they have managed to replicate sufficiently well. Language evolution takes place, in other words, primarily because the elements that constitute languages are replicators which strive to propagate. The needs of speakers only represent constraints on the propagation of linguistic replicators, determining which of them will survive more easily in an environment where resources (in this case electro-chemical energy supplied within human brains) are as limited as they are anywhere within our world.

CONTROVERSIES IN MEME THEORY

By

Nick Rose

University of the West of England, Bristol. UK.
And the 'Meme Lab'.
Nicholas.Rose@uwe.ac.uk

Abstract

Meme theory and the notion of cultural evolution present the possibility of a fundamentally new way of understanding human culture. Yet some of the speculation within meme theory has become confusing and ambiguous. Four areas of meme theory are critically reviewed. These are ambiguity in the definition of a meme and confusion regarding the distinction between replicator and phenotype, the problem of inheritance of acquired characteristics, the relationship between memetics and sociobiology, and the selection or mutation of memes being carried out by conscious foresight. Whilst I suggest directions which might resolve these problems, the purpose of this short review is to help generate the wider debate required to settle these important issues.

Keywords: meme theory, replicator, phenotype, Lamarckism, sociobiology, self-centred selectionism, Cloak, Dawkins, Dennett

1 Introduction

Evolution by natural selection has been controversial since Darwin first published 'The Origin of Species' in 1859, not least amongst those who hold religious beliefs. By demonstrating that through the accumulation of small inherited changes and differential survival, 'nature' could select animals upon the basis of their suitability to their environment, Darwin achieved an explanation of how complexity and apparent design could have arisen in nature without the need for a designer. Perhaps the most controversial aspect of Darwin's theory was that it challenged the view that 'Man' was somehow separate from the rest of nature. Human beings were merely another branch of life, stemming from the same evolutionary process and primitive beginnings as all other animals.

Despite the controversy, Darwinian evolutionary theory has succeeded in becoming a central feature of the biological sciences. The theory has undergone some refinement during the time it has been around; not least with the unification in the 1930's with the genetic mechanism of heredity (e.g. Fisher [22]). Essentially, however, it could be said that Darwin's theory is the centre piece of biology, the basis for explaining the origins and history of life on Earth, and perhaps everywhere else in the universe (c.f. Dawkins [17]; Dennett [19]).

The core tenets of evolution by natural selection 'are as much open to doubt as the theory that the earth goes round the sun' (Dawkins [15], p1). Advances in sociobiology and evolutionary

psychology attempt to use the strength of this theory to generate explanations of human behaviour by seeking possible genetically based evolutionary adaptations (e.g. Barkow, Cosmides, and Tooby [2]). However, it is clear that human beings differ from other animals on Earth by the complexity of their culture. By apparently seeking to explain all human behaviour in terms of biology, sociobiology has found itself accused of what Dennett [20] calls 'greedy reductionism'. It is clear that much of human culture requires a more appropriate level of description. Although the level of the gene may not fulfill that requirement, it remains to be determined whether evolutionary theory could be more widely applied to incorporate human cultural change. It has been suggested that cultural complexity may have arisen through mechanisms analogous to those responsible for the formation of organic life, leading to the attempt to create a theory for the evolution of culture.

Memetics takes the Darwinian revolution one step further. Evolutionary theory explains how complexity and apparent design could emerge within nature without the need of a designer. In the case of culture the 'designer' could be the 'common sense' notions of 'free will', 'intentionality', or 'Self'. In a way memetics appears to attempt to replace the 'Self' (c.f. Blackmore [5]; Dennett [19]) with an algorithm of culture in the same way that Darwin and his successors have replaced 'God' with an algorithm (c.f. Dennett [20], p 50) of life. We can expect the future of memetics to be a difficult and controversial one.

Universal Darwinism (Plotkin [32]; Dawkins [15]) and its application to culture provides a rich and exciting source of speculation from a wide variety of disciplines. Meme theory, in particular, has proved fertile ground for such theorising. Whilst much of this theory has been good, some of it has become confusing and ambiguous.

This paper will offer a critical review of four areas of meme theory. These involve difficulties for the theory which I suspect are also of concern to many people both within, and outside, memetics. I have views as to how each of these problem areas could be settled. However, the purpose of this paper is to give a short review of these areas in the hope of stimulating something of the wider debate required to find solutions for these problems.

2 Replicators and Phenotypes

The definition of a meme is currently ambiguous. A meme can be found variously described as; a unit of imitation (Dawkins [15]), a unit of information residing in a brain (Dawkins [16]), culturally transmitted instructions (Dennett [19, 20]), any permanent pattern of matter or information produced by an act of human intentionality (Csikszentmihalyi [14]), roughly equivalent to ideas or representations (Plotkin [32]), a unit of information in a mind whose existence influences events such that copies of itself get created in other minds (Brodie [9]), actively contagious ideas (Lynch [28]), a mental representation (Gabora [23]), a self-replicating element of culture passed on by imitation (Oxford English Dictionary), etc. Without some kind of firm definition the word 'meme' becomes almost meaningless (c.f. Wilkins [35]) applied to instructions in brains, information, behaviour, words, mental states, books and all kinds of cultural artefacts without consistency.

Dawkins [15] used genes as an analogy for memes and recognised that the analogy had natural limitations. It is difficult to recognise anything like a memetic allele (although Durham [21], refers to `allomemes') or memetic chromosomes, for instance. Dawkins [15] suggested that the meme is still "drifting clumsily about in its primeval soup" (p 206) much like early replicating molecules, and might have a very different mechanism for competition such as memory space in the brain. Thus Dawkins [15] appears to resist any definition of a vehicle of culture or memetic phenotype.

Wilkins [35] attempts to clarify this analogy by tracing Dawkins' conception of memes from Williams' evolutionary gene and examining Hull's (e.g. Hull [26]) distinction between replicator and interactor. I'd like to take an alternative approach and trace Dawkins' conception of memes from Cloak's [12] work on cultural ethology. Cloak attempted to lay the foundation for applying ethological methods to the study of culture-specific human behaviours. Cloak's [12] definitions are much less confused, and thus perhaps more useful, than the definitions for memes. He calls the set of cultural *instructions* people carry in their nervous systems, `i-culture'. The *material* structures, relationships among material structures, and changes in these relationships which are actually brought about or maintained by behaviours of those cultural instructions, he calls, `m-culture'. Features of m-culture thus include features of their behaviour, their technology, their social organisation, and when considered as a set of verbal behaviours, ideologies. Cloak [12] summarised the i-culture-m-culture interaction in a way which makes the link to Dawkins' subsequent formulation of memes and their phenotypes quite apparent.

"An i-culture builds and operates m-culture features whose *ultimate function* is to provide for the maintenance and propagation of the i-culture in a certain environment. And the m-culture features, in turn, environmentally affect the composition of the i-culture so as to maintain or increase their own capabilities for performing that function. As a result, each m-culture feature is shaped for its *particular* functions in that environment." (Cloak [12], p 170, original italics).

Dawkins' [15] examples of memes, such as, pots, arches and clothes fashions, would naturally belong to Cloak's [12]) `m-culture'; only the cultural instructions inside the brain which produced these artefacts would be considered the replicator whose `purposes' are being served by these things. Dawkins [16] later clarifies his position by adopting the i-culture-m-culture distinction; "I was insufficiently clear about the distinction between the meme itself, as replicator, on the one hand, and its 'phenotypes effects' or 'meme products' on the other. A meme should be regarded as a unit of information residing in a brain (Cloak's 'i-culture')." (Dawkins [16], p109).

Despite this helpful clarification the distinction between memes and their phenotypes has been overlooked by subsequent authors, adding to the confusion generated by Dawkins' [15] lack of clarity. For an example of such confusion I would like to use Dennett's [19, 20] now famous maxim;

"A scholar is just a library's way of making another library." (Dennett [19], p 202; [20], p 346) Whilst there is no doubting the shock value upon the reader, Dennett's maxim is quite problematic. One could compare Dennett's [19, 20] statement to the (Batesman [3]) quotation; "a bird is the nest's way of making another nest", in genetics. Dawkins [16] points out that Bateson's remark, which arose from an argument that genetic determinants of development are necessary

but not sufficient, is wrong in Dawkins' view because the nest is not a replicator. The gene is the replicator, and both the bird and the nest are phenotypic expressions of those genes. As Dawkins [16] puts it; "A nest, like a bird, is the gene's way of making another gene." (Dawkins [16], p98)

Dennett appears to suggest that we should consider that a library (presumably the 'information' housed within a library) is a replicator, and the scholar (a person who studies books) a phenotype. However, Dennett [20] goes on to suggest that language (oral or written) is a 'vehicle' for invisible memes, which are the cultural replicators. This would suggest perhaps that Dennett does not hold the position that a library is a replicator, but something like a meme vehicle. In which case we might be better off saying that; libraries, as vehicles for the memes, serve to promote the replication of those memes (among scholars). Not as punchy as the original, but much clearer I think, and also consistent with Cloak's [12] original work, where a library would be a class of m-culture, the function of which is the maintenance and propagation of i-culture.

There are two points I hope to have brought out from this brief review of the problem. Firstly, that some of the problems of defining memes and making a firm distinction between replicator/phenotype, stem from Dawkins' [15] lack of clarity and the overlooking, by subsequent authors, of Cloak's [12] work and Dawkins' [16] correction. Secondly, that Cloak's [12] work is worthy of greater consideration than it currently appears to enjoy, as it generates some rigid definitions and distinctions which much of memetics has so far lacked.

3 Lamarckian Heredity

Why did such usually clear and consistent writers fudge the important issue of replicator/phenotype distinction? I suspect one reason was because Dawkins and contemporaries realised that they were proposing an evolutionary system which appeared to work on Lamarckian-like principles - that is, a system which involved the inheritance of acquired characteristics. Given that Darwinists had spent the best part of 100 years trying to explain why biological evolution was not Lamarckian and trying to undo some of the misconceptions generated by this alternative model, it seems possible that they drew back at the last for fear of resurrecting an old 'enemy'.

Lamarckian heredity is now widely rejected as the mechanism for inheritance within biological systems (although there have been occasional scares, see Dawkins, (1982) [17]. Lamarck's theories on evolution and inheritance have been often mis-represented or mis-understood, (c.f. Hull [26]). Within memetics we tend to refer to the fact that culture is acquired by directly copying the phenotype as 'Lamarckian' (e.g. Boyd and Richerson [8]). Put simply, the view that a blacksmith's son will inherit the developed arm muscles of the blacksmith is as simply untrue as the idea that a dog which loses a leg will give birth to three legged puppies. Organisms do not appear to inherit the changes made to the phenotype during the lifetime of the parent organism. Although this is untrue for biological systems, something like Lamarckian inheritance may exist for cultural systems.

Short of some kind of telepathy it is difficult to see how instructions for a cultural behaviour inside one person's brain could be transmitted to another person's brain without the mediation of

a phenotype. The mediation of the phenotype may be enough to call cultural inheritance 'Lamarckian', but of more interest is the question of whether accidental deviations in the phenotype are acquired by the new host. As Blackmore [4] explains, this is not always the case. She gives the example of telling a story with a hoarse voice. When the new host of the story retells the tale, they do not do so with the same hoarse voice. It may be the case that human beings are very resistant to this kind of 'Lamarckian' inheritance, and that changes accidentally acquired by the phenotype are not automatically adopted by potential hosts.

Although some theorists (e.g. Boyd and Richerson [8]; Gabora [23]) appear certain that cultural inheritance is 'Lamarckian', others (e.g. Dawkins [16]; Hull [26]; Blackmore [4]) seem to have reservations, and question the relevance of the term when applied to cultural evolution. In one sense there is a causal arrow from phenotype to replicator in that the synthesis of a cultural instruction proceeds from the interaction of a potential host and the phenotype of that instruction; and this may be called 'Lamarckian'. In another sense the system appears remarkably resistant to accidental noise within the phenotype, often synthesising the cultural instruction without that acquired characteristic of the phenotype. It is not clear whether cultural inheritance is Lamarckian (in the sense given above), or merely occasionally Lamarckian. Therefore, it seems sensible to conclude that cultural inheritance is mediated through the phenotype, and that the possibility exists that characteristics acquired by the phenotype can also be inherited. It may be better to drop the term 'Lamarckian' altogether (c.f. Blackmore [6]).

Does this imply a causal arrow between the phenotype and the replicator? (Dawkins [16] concern). It does, but only in that changes to the phenotype may be synthesised as 'mutant' instructions in the brain of a host that comes into contact with it. In this way it appears that the mechanism of transmission is simply another example of the difference between memes and genes. Copying the phenotype (when the phenotype has been accidentally changed) could be said to sometimes cause the creation of mutant memes. This form of 'Lamarckism' could be seen as just another potential source of copying infidelity in meme transmission. The 'meme-line' for the construction of the original meme phenotype has ended, and a new mutant 'meme-line' has sprung up. Whilst this is certainly a 'problem' for memes (as all copying infidelity is a problem), it does not necessarily cloud the distinction between memes and their phenotypes or prevent cultural evolution from being considered Darwinian.

Indeed the problem of copying infidelity may give us insight into the deeper mystery of why humans have evolved such complex culture whilst no other animal on Earth has done so. Nature abounds with examples of cultural transmission (e.g. Bonner [7]), but humans appear unique in the complexity and variation of their culture. Many writers have speculated as to the cause of this disparity for example; creativity (e.g. Gabora [23]) or Machiavellian intelligence (e.g. Byrne and Whiten [10]).

Dennett [20] suggests that for cultural evolution to occur the fidelity of transmission must lie within a particular range. The fidelity cannot be 100% because culture would have no variation; which is required for differential survival to drive evolutionary change. The fidelity must still be very high, or else culture would have no continuity between individuals and 'Good Tricks' (Dennett [20]) would be lost as quickly as gained, and again evolution would not occur.

One might speculate that at some stage of evolution human imitation progressed to the point where it crossed a fidelity threshold. It became high enough fidelity for 'Good Tricks' to survive for some time in the system (c.f. Maynard Smith and Szathmary [29], who model permissible genome size as a function of replication accuracy for viruses). It is easy to forget just how hard imitation is, humans are so good at it. Few other species have been shown to truly imitate one another, and none are anywhere near as proficient at the task as even human babies (c.f. Heyes [25]; Meltzoff and Moore [30]). If transmission fidelity is a key factor responsible for the complexity of our culture we would expect normal adults to be well within the expected range of fidelity, whereas humans (e.g. autistic children perhaps) and animal groups which do not readily develop complex culture would not.

4 Sociobiology and Memetics

Evolution by natural selection, with the gene fulfilling the role of the replicator, provides formidable explanatory power when applied to biological systems. Dawkins [15, 17] demonstrates how the idea can not only account for complex biological structures, such as the eye, but also social behaviours, such as patterns of aggression. Altruistic behaviour, which appeared a thorn in the side of 'nature red in tooth and claw' models of evolution, received special attention. Biologists, (e.g. Hamilton [24]; Trivers [35]; Dawkins [15]; Cronin [13]; Axelrod [1]; Ridley [33]) have used the 'gene's eye-view' to provide convincing explanations of altruistic behaviour among animals through mechanisms such as kin selection and reciprocal altruism. Considering evolution from the point of view of the selfish gene has also given new life to explanations of flamboyant features among animals, such as the peacock's tail, by allowing a better understanding of the mechanisms of sexual selection (e.g. Cronin [13]).

Despite the success of sociobiology in illuminating possible evolutionary mechanisms which lead to particular forms of human behaviour, many aspects of culture remain beyond the aegis of neo-Darwinian explanation. It is apparent that the evolution of biological phenotypes cannot completely explain the panoply of behaviours which humans exhibit. Kin selection, sexual selection and reciprocal altruism may well describe the mechanisms which operated to form, for example altruistic behaviour, but much of the specifics of those behaviours are not adequately explained by sociobiology. The mechanisms sociobiologists examine allow us to understand why altruistic behaviour evolved in the first place, but examples like blood-donation, where the donor appears to receive no (biological) benefit in return, or adoption, where parents invest in non-kin, appear to require additional explanations.

There appears to be a feeling, particularly among psychologists and sociologists that perhaps sociobiology has gone too far (e.g. Rose [34]), a resistance to what some see as 'greedy reductionism' (Dennett [20]). It is apparent that there needs to be a theory which attempts description of human behaviour at a more appropriate level of analysis.

However, some proponents of meme theory often appear to undervalue sociobiological explanations for behaviour. Meme theory should only be applied where Occam's razor allows. A theory of cultural evolution should incorporate sociobiological findings, only calling upon the addition of cultural mechanisms where they are necessary in order to accurately describe or explain behavioural phenomena. An example from Lynch [28] illustrates this point.

"Eating abundant high-fat food causes people to gain weight as they age. So women's body-fat percentage now correlates with their age. But men who prefer young women can lead longer reproductive careers, replicating their memes into more sons. By thus favouring young women, the lean-partner preference out replicates the fat-partner preference in modern well-fed societies." (Lynch [28], p 87)

Whether or not this example is true (and there are no sociological references in support of the claim made), Lynch [28] gives us no clue as to why we should ascribe lean-partner preference to purely cultural factors. In the example simply replacing the word 'meme' with 'gene' could make it a sociobiological argument. Surely genes which promote men to have sexual relationships with younger women (because of their longer reproductive careers) could lead to a 'lean-partner preference'.

As well as over-relying upon the power of 'vertical' transmission of memes ('vertical' refers to cultural transmission from parents to children, c.f. Cavalli-Sforza and Feldman [11]), this kind of memetics does not tackle the possibility of other mechanisms for culture (e.g. 'epigenetic' rules; Lumsden and Wilson [27]), and overlooks possible genetic biases in cultural selection and the explanatory power already available from sociobiology. We should not ignore or attempt to rewrite the advances made by sociobiology. It seems likely that there will be many instances where memes and genes have co-evolved (e.g. Durham [21]) 3, particularly when the majority of cultural transmission has been 'vertical'. If we wish to look for examples of apparently 'independent' cultural effects on human behaviour, it might be more profitable to look at biologically maladaptive behaviours which have arisen from predominantly 'horizontal' transmission (i.e. cultural transmission between non-kin, c.f. Cavalli-Sforza and Feldman [11]). Where cultural practices appear to directly increase the chances of biological reproductive success we should acknowledge them as co-evolutionary systems (e.g. Durham [21]) and recognise the important contribution of biology to many of our behaviours.

5 Self-centered Selectionism

Finally I would like to examine what I believe is a major misconception which has found its way into memetics. I shall call this misconception Self-centered selectionism. Perhaps Dawkins himself provides the most famous example;

"We are built as gene machines and cultured as meme machines, but we have the power to turn against our creators. We, alone on earth, can rebel against the tyranny of the selfish replicators." (Dawkins [15], p 215)

On the very last page of *The Selfish Gene*, Richard Dawkins closes his argument with a call to overthrow the tyranny of the replicators. In doing so it could be claimed that he committed a common, but fundamental, error; he assumed there was 'someone' beyond the constructs of the memes and genes who could do the overthrowing.

The idea that a Self, beyond the constructs of the genes and memes, can select or design memes is what I call 'Self-centered selectionism'. Self-centered selectionists claim to accept the idea

that memes are the unit of cultural heredity, and even that memes have 'power' to influence behaviour; but then contradict themselves by claiming that it is the 'conscious Self' which selects which memes a person has in 'their' brain. This is the sentiment echoed throughout Csikszentmihalyi [14], and Brodie [9]. The 'someone' beyond the construct of the memes and genes is 'consciousness', they claim. It is apparent that both of them believe that consciousness has the power to select memes in order to fulfill some life goal.

"After all, our genetic program, laid down before our ancestors achieved consciousness, dictates that we place all our efforts into what it takes to replicate our own genes. ... Yet there are also many people for whom the goals of survival and reproduction are not sufficient. It is for these individuals that the possibility of contributing consciously to evolution might be a very attractive proposition." (Csikszentmihalyi [14], p 168)

"You can consciously program yourself with memes that help you with whatever you're up to in life. That's one of the main strategy-memes in the memetics paradigm. It goes against that strategy to believe religious dogma without having consciously chosen it as empowering to your own life." (Brodie [9], p188)

The other idea they both appear to support is akin to the idea of 'directed mutation'; a paradoxical position whereby mutation that occurs is not random, but somehow directed towards some goal. The claim that variation is directed by human intentionality appears utterly incompatible with the idea of culture as an essentially Darwinian evolutionary system. "At the moment of creation, the meme is part of a conscious process directed by human intentionality." (Csikszentmihalyi [14], p 120)

"In the not-so-distant future, the bulk of our culture will be composed of designer viruses. Why? Because now that we know how to do it, we will. We will conquer the conceptual landscape as surely as we conquered the wilderness. At first, designer viruses will compete with cultural viruses for a share of our mind. Soon the old cultural viruses will lose, because the natural selection with which they evolve is not as quick as the intelligence-directed creation of designer viruses." (Brodie [9], p 200)

The claim that we can intentionally design and choose memes begs the question; 'why do we need an evolutionary theory at all?'. If the processes of meme selection are not 'natural', one is perhaps left with 'conscious foresight' picking and choosing memes towards some goal. Even if we ignore the very real issue of consciousness doing anything, this is still entirely at odds with the proposal that culture is an evolutionary system.

Given the complexity and variety of life found on Earth it is not surprising, perhaps, that in the past people have looked to that complexity as evidence for the existence of a God or supreme designer. William Paley [31] used the example of finding a watch on a deserted heath, and that from the complexity and apparent design of the watch one could infer the presence of a designer. By analogy, he claimed, because complexity and apparent design exists within nature, nature too must have had a designer. Paley was firm in the claim that; "Arrangement, disposition of parts, subserviency of means to an end, relation of instruments to a use, imply the presence of intelligence and mind", and his belief that; "There cannot be design without a designer". It is this

view which has been roundly defeated by the Darwinist revolution within the biological sciences. In biological evolution it is unnecessary to posit some external influence, or guide, or God which directs evolution along. Natural selection can account for the evolution of complexity and design without a designer, without foresight.

If memes are not selected by the same sorts of `natural' processes which affect genes, it becomes difficult to understand how memes could be said to have `phenotypic power', or any other kind of power for that matter. If one believes God meddles in biology, one need not posit evolution to explain the forms we find in biology. Likewise, if one believes that `consciousness' has the foresight and independence to select and direct behaviours towards some goal, one need not posit evolution to explain the forms we find in culture.

People choose memes, but people are constructs of memes and genes. If meme theory is to be given serious consideration then we must first reject the notion that some `central executive Self' can pick and choose among the memes, and refer instead to the sorts of filters (c.f. Dennett [19]) which memes and genes have constructed. Dennett [19] suggests it is the memes which already occupy the brain which influence the brain to accept or reject new memes which come along.

"But if it is true that human minds are themselves to a very great degree the creation of memes, then we cannot sustain the polarity of vision with which we have started; it cannot be `memes versus us' because earlier infestations of memes have already played a major role in determining *who or what we are*. The `independent' mind struggling to protect itself from alien and dangerous memes is a myth; ..." (Dennett [19], p207, original italics)

Understanding the `natural' selection pressures upon memes is of fundamental importance to meme theory. To attribute selection to conscious foresight, ignoring that (short of some kind of precognition) foresight does not really exist, not only undermines the value of meme theory as an evolutionary process, it is also a kind of giving up. Meme selection is already a big enough mystery without introducing the complex and enigmatic concept of consciousness. We might as well attribute meme selection to magic, for all the progress that *will* achieve.

6 Conclusion

I have briefly, and critically, reviewed four important areas which I believe are central to meme theory. The difficulties which I have covered generate concern both within and outside memetics and which need some kind of resolution before major progress can be made towards a science of memetics. Whilst I have aired my views as to how the difficulties in these areas might be settled, these aspects of meme theory can only really be resolved through further debate and eventually research. It is my hope that these short reviews will go some way to stimulating that process.

Notes

1. I mean `Self' in the same sense that Blackmore [5] refers to. Blackmore suggests that there is no `Self' beyond a construct of memes, no one to `have' a belief, or `own' an idea. She suggests that the illusion of a `Self' is itself a meme-complex (i.e. a collection of co-adapted memes)

which is 'unzipped' by Zen training. This general line of thinking is similar in direction to some of Dennett's ideas in *Consciousness Explained* [19].

2. An 'Algorithm' in the sense that Dennett [20] uses the term is broadly characterised as a 'foolproof and somehow "mechanical" procedure' (Dennett [20], p 50). Here I use the term to underline the essential 'mindlessness' of the process involved (i.e. not directed by foresight or a 'Self').

3. Durham [21] uses the idea of memes in his book 'Coevolution'. He provides some excellent examples and analysis where genes and memes have co-evolved in particular cultures. In his view memes can alter the behaviour of humans in such a way that certain genes are favoured over others; e.g. cultural beliefs about dairying and fresh milk consumption affect the reproductive fitness of genes for adult lactose absorption. Durham comes to the conclusion that evolution involves a dual inheritance system, genetic and cultural; which interact with each other in predominantly co-supportive ways. Whilst this may be true when memes and genes share the same vector of transmission (i.e. from parents to kin), it is likely that when memes begin to use lateral transmission (e.g. to non-kin) they can begin to behave more independently of biological advantage, sometimes leading to biologically maladaptive behaviours (c.f. Cloak [12]).

OKAY, BUT EXACTLY “WHO” WOULD ESCAPE THE TYRANNY OF THE REPLICATORS

Reply to the commentaries on the author's paper: Controversies in Meme Theory

By

Nick Rose

Department of Psychology
University of the West of England
Fishponds, Bristol, BS16 2JP
Nicholas.Rose@uwe.ac.uk

The section of my paper entitled Self-Centered Selectionism actually dealt with several issues, which was clumsy of me. To help rectify this I shall respond to the commentaries by attempting to divide up the issues.

1 Self-Centered Selectionism and Self-Centered Variation

In a Darwinian system the random variation among the replicators allows differential survival to drive evolutionary change. The meme 'eye view' of this process has been characterised by Blackmore (1997) "*...imagine a world full of hosts for memes (e.g. brains) and far more memes than can possibly find homes. Now ask - which memes are more likely to find a safe home and get passed on again?*" The problem, as I see things, with the ability to consciously choose or reject which memes we have is that it shifts the focus of cultural selection away from the characteristics of the 'meme' and instead concentrates upon the properties of consciousness (with all the associated problems). I am happy to accept that people choose memes - and that they do so in a non-random or directed way. However, I would insist that whatever is directing the selection of memes we are better off examining genetic predisposition and the memes already in situ and trying to understand the differential survival of memes - before resorting to the more enigmatic properties supposed of the mind. Just as the environment for genes includes other genes (and their vehicles), the environment in which memes differentially survive includes other memes. It is these genes and other memes, perhaps in the form of 'filters' (c.f. Dennett, 1991), which I believe make up the 'self' which selects memes.

At the last I have no great argument against the possibility of conscious foresight or intention selecting memes, and I have no trouble admitting this. For me it simply focuses the debate in a rather unpromising direction - and represents a kind of giving up. To that extent I find myself in general agreement with David Hull and Derek Gatherer. One point of contention with Hull is the question of Artificial Selection. Hull suggests that because I rule out intentionality in memetic evolution - that I reject also Darwin's argument that the goals of conscious agents play a crucial role in artificial selection. This is ironic because Darwin spends a large section of his first chapter in 'The Origin of Species' undermining the extent of conscious selection - for his argument builds towards natural selection from the premise of unconscious artificial selection having a crucial role in the form and character of domestic animals. But, nit-picking aside, the example of artificial selection (and modern genetic engineering) is a misleading one. Cultural

practices which have effects upon the phenotypes of animals are (we might claim) the result of memetic evolution. Selective breeding is not random, but then neither is natural selection. The selective environment for domesticated animals also includes humans who, through the course of cultural evolution, have discovered ways of exploiting them and even manipulating their characteristics at the genetic level. I still feel that this does not require conscious foresight to guide meme selection - merely evolved cultural practices to guide the selection of genes in animals. I find this compatible with Darwin's observations and preferable to introducing conscious foresight.

There are many aspects of John Wilkins's commentary with which I agree, but he insists at the last upon the intending self as a social agent. He writes; "*If memes are selected for or against intentionally on the basis of prior experience and propensities to estimate the likely success of a given strategy, that will deform the fitness landscape for these memes and meme-bearers.*" If I could strike the word 'intentionally' I would find myself in perfect agreement. I find the word 'intentionally' utterly redundant here, adding nothing to the description of the process. The 'intentional stance' (c.f. Dennett, 1991) is an excellent heuristic - it allows us to form quick and ready predictions about the behaviour of another - whether that other is Wilkins's lion or another person. Whilst such a 'theory of mind' is undoubtedly useful, I would say (probably along with Dennett) that it is only a convenient short-hand. I might use a similar short-hand to describe other non-intentional processes, for instance; the salt molecules seek areas of low concentration, or the phototropic plant wants to grow in the direction of light. But, at the end of the day it is merely a short-hand for a more complex, and essentially passive, process. Wilkins suggests that the 'self' (as a social agent) has some control over the kinds of memes it hosts, not unlike the control our immune system has over the sorts of micro-organisms that a body hosts. However, we don't require 'immuno agency' to understand the immune system - so why introduce 'social agency' to understand culture? Whilst it may be 'bleeding obvious' to Wilkins that intentions play a part in evolution, I would say it is a short-hand which is 'bleeding redundant' to understanding selection.

Hull is right; I don't care very much for such 'selves'. I find attributing meme selection to a 'self', which exists beyond the constructs of memes and genes, redundant, misleading and lazy. Whilst George Modelski may be right that there is no 'inherent contradiction' between self-centered selectionism and Darwinian evolution, I would agree with Gatherer and Hull who suggest that it is a position unhelpful to the development of memetics. However I maintain that what is essentially fatal to the argument that culture evolves along Darwinian lines is the suggestion that meme variation is a product of a process directed by conscious intentionality and foresight; which I shall dub 'Self-Centered Variation'. If variation among memes is somehow directed by consciousness towards some goal then it is not a Darwinian process. None of the commentators appeared to argue against this position, so I shall hesitantly assume that they were in general agreement.

2 Tyranny and Freedom

Memetics poses some difficult questions about free will and the self. Francis Beer describes the uneasy coexistence of free will and determinism within our thinking and theorising and perhaps it is this underlying tension which so often produces impassioned argument. I have nothing

against using the term 'free' in a legal or political sense, indeed these are definitions of freedom which make some sense to me. Certainly a slave has, in a very practical sense, less freedom than I do. However, whatever freedoms I enjoy only exist by convention of the society in which I live. Whenever we speak of freedoms, in a political or legal sense, we also recognise responsibilities. In many instances 'responsibilities' represent things which we are not 'free' to do. As Beer rightly points out, these meanings are themselves 'fluid' and subject to the selective forces we seek to use to explain other aspects of our culture.

Ifryn Price attempts to find a compromise in this debate and seeks to soften the dramatic claim made by Dawkins (1976) which I felt typified the Self-Centered Selectionist error (c.f. Rose, 1998). He writes; "*Perhaps it is only through the memes / genes for the inquiring mind and an appreciation of the power of selfish replicators that we may at last escape at least some of the tyranny.*" I would add with a touch of cynicism; 'and run headlong into other tyrannies'. However, to describe the genes or memes as 'tyrants' in the first place is certainly a 'literary excess' - for we are the products of these memes and genes. I find the distinction between us and our genes or us and our memes distinctly odd (and one which smacks of Dualism). At the end of the day who would escape the tyranny of the replicators? To escape the tyranny of memes we should surely have to lose the ability to imitate and instruct and culturally transmit information to one another - and have minds unshaped by culture. To escape the tyranny of genes we should surely have to lose the ability to reproduce - and have bodies and brains unshaped by biology. Not only would such a revolution be impossible, but who would be left after the revolution to enjoy the victory?

DARWINIAN SOUP

Review of *The Meme Machine* by Susan Blackmore · Oxford, 264 pp, £18.99

By

W.G. Runciman

LRB | Vol. 21 No. 12 dated 10 June 1999 | W.G. Runciman

The word 'meme', popularised by Richard Dawkins in *The Selfish Gene*, has recently gained entry into the *OED* as 'an element of a culture that may be considered to be passed on by non-genetic means, esp. imitation'. But the idea that culture is transmitted by imitation and learning in a manner analogous but not reducible to natural selection has been around for a long time, and many other terms have been used in describing it. Darwin himself, when he came to consider 'the causes which lead to the advance of morality', concluded that 'natural selection effects but little' and looked instead to such things as 'the approbation of our fellow-men' and 'example and imitation'. Much later, when the mechanism of natural selection had come to be understood in greater depth and detail than had been possible for Darwin himself, the American psychologist Donald Campbell and others began to develop the notion that cultural evolution (including the emergence of such things as theories of cultural evolution) is also driven by a competitive process of variation and selection. Campbell called his Presidential Address of 1975 to the American Psychological Association, 'On the conflicts between biological and social evolution and between psychology and moral tradition'. But how does cultural evolution actually work? Any reader sufficiently interested in that question to read this review is likely to be aware that current discussion of it is permeated by controversy. The controversies are of two kinds. For some opponents of 'memetics' in any guise, the mere idea of it is totally misconceived, whether because (as the Reductionists argue) cultural evolution is really all about the workings of our genes, or because (as the Creationists argue) it's really all about the souls implanted in us by God, or because (as the Post-Modernists argue) no so-called theory of cultural evolution will ever explain it any better than any other so-called theory. There are also not a few anthropologists and sociologists for whom the mere association of 'memes' with the name of Dawkins is enough to rule them out of mention in correct academic society. But to those, including myself, for whom the ideas of heritable variation and competitive selection are much the most serious game in town when it comes to explaining, and not merely narrating, the course of human sociocultural evolution, the issue is not whether to incorporate culture as such within neo-Darwinian theory, but how.

The disanalogies with natural selection are obvious, and Susan Blackmore is well aware of them. There aren't, literally speaking, lineages of memes as there are of genes, and memes, unlike genes, can be discarded by the people who carry them and replaced by others. Moreover, the relation of the information encoded in memes to the rituals and artefacts of a given culture is not at all the same as that of the information encoded in genes to the organisms which carry them. But it doesn't follow that memes can't therefore be replicated and diffused by what is still a process of heritable variation and competitive selection. Some neo-Darwinian theorists, although they agree that in the human species genetic is supplemented by cultural inheritance, insist that the function of memes is still to serve the interests of genes: cultural mutations will continue to be replicated only if they somehow enhance, on average, the inclusive reproductive fitness of their carriers. But although that may be true in the long run, it demonstrably isn't true in the short

- and the short run covers some of the widest and most significant divergences between the cultures of the different human populations in the ethnographic and historical record. Blackmore firmly, and in my view rightly, sides with those who maintain that 'memetic' mutations can be culturally adaptive - that is, can be such that their continued replication will be favoured by the relationship of their carriers to their environment - even when they are at the same time genetically maladaptive - that is, such as to reduce the probability of replication of the genes of the people who carry them.

But what is - or isn't - a 'meme'? Blackmore sensibly eschews any attempt to find precise 'memetic' analogies for genetic concepts like alleles, meiosis and so forth. But having reviewed some of the many conflicting opinions in the current academic literature, she concludes that the best thing to do is to 'use the term "meme" indiscriminately to refer to memetic information in any of its many forms; including ideas, the brain structures that instantiate those ideas, the behaviours these brain structures produce, and their versions in books, recipes, maps and written music'. This is not only confusing, but defeatist. It is true that there is no single model which can capture everything involved in the transmission of culture from adjacent or successive populations to one another. But if 'memetics' is, broadly speaking, about the way instructions affecting phenotype are transmitted from mind to mind by imitation and learning, it is presumably worth drawing an explicit distinction between the instructions transmitted, whether visually, orally or in written form, by parents, teachers, peer-group members or role-models, and the behaviour which the instructions dictate. Nobody can deny that such transmission is happening every day. Why, then, should even those whom Daniel Dennett calls 'Darwin-dreaders' object to the adoption of a single word for whatever specific bundles of instructions affecting phenotype - whether encoded in gestures, speech, writing or any other medium - do in fact guide the behaviour of the members of different cultures or sub-cultures?

The carriers (or as Blackmore prefers it, 'vehicles') of 'memes' are then the minds in which the instructions are held, and the behaviours which result from following the instructions - cooking soups, building churches, singing songs, wearing hats, performing plays, giving birthday parties - are the memes' phenotypic effects. The instructions do not, however, have to be strictly deontic in logical form, or strictly prescriptive about every detail of behaviour. 'Memes' can include discrete units of memorable information (whatever they are) within the totality of values and beliefs which guide our cultural behaviour, as well as mental representations (however they function) of recipes, drawings, musical scores, prayer-books, folk maxims, manuals of etiquette and so forth. The different individual 'cultures' of the human populations in the ethnographic and historical record then consist of sets of related 'memes' (Blackmore calls them 'memeplexes') which have been handed down sufficiently widely and accurately over a sufficient number of successive generations to amount to a definable cultural tradition.

Not even the blessing of the *OED*, however, has converted to 'memetics' more than a handful of the increasing number of behavioural scientists, from archaeologists to linguists to economists, whose studies of one or another aspect of sociocultural evolution are conducted within a recognisable neo-Darwinian paradigm. This may in part be due to an innate suspicion of neologisms. But it is also due to a widespread feeling that 'memes' sound too much like 'genes' for the significance of the disanalogies between them to be allowed for, that the use of the word provokes more definitional quarrels than it resolves evidential disagreements, and that until we

know much more than we do about where and how instructions affecting phenotype are stored in the human brain it is premature, if not seriously misleading, to talk about their replication and diffusion as if we did. Blackmore's answer is to remind us that the theory of natural selection made enormous advances long before the underlying chemistry was understood and to claim that for all our ignorance about how memes are stored and transmitted 'we certainly know enough to get started.' But even those of her readers who are willing to assent to that proposition may be startled by her headlong gallop into problems as complex and intractable as language, altruism, religion and human self-consciousness itself.

The puzzling question about language, as Darwin observed, is why linguistic ability hasn't evolved in other apes as well as humans. In both humans and other primates, there is a correlation between increasing group size and increasing size of the neocortex. But what were the ecological conditions which allowed the benefits of progressively bigger brains to outweigh the heavy energetic costs? And what exactly were those benefits? As Blackmore acknowledges, we have almost no idea when our remote forbears started using language, let alone what language was first used to say. Her claim that their brain size was 'created by memes' - 'memes' here standing for the newly evolved capacity for genuine imitation, as opposed to mere stimulus enhancement or operant conditioning - is purely speculative. It isn't even as if genuine imitation hasn't been observed in other species. Primatologists are divided about what sort of evidence is conclusive for this purpose, but Darwin had no doubt that 'apes are much given to imitation.' Might not language have helped the replication of memes more than memes helped the replication of genes responsible for the 'language instinct'? Without a more detailed model of the feedback between the greatly enhanced capacity for imitation which Blackmore assumes to go with language and the physiological and anatomical changes which language required, it is difficult to see how the strength of her claim can be assessed. Her fellow-psychologists would probably agree that there is strong evidence for a link of some kind between the acquisition of language and the acquisition of a theory of mind which enabled our remote forebears to conceptualise other people as such. But nobody (yet) knows what it is, and invocation of 'memes' isn't enough to furnish the answer.

Similarly, it is far from clear in Blackmore's discussion of altruism how the strength of her claim that 'meme-driven' altruism spreads because people 'infected with altruistic memes . . . are copied more than other people and so these memes spread more widely' is to be tested. There is no lack of evidence that human beings will, under some conditions, behave generously towards others who are not their genetic relatives, and will sometimes do so even where they have no reason to expect that the recipients of their generosity will at some later stage do them a favour in return. But equally, there is no lack of evidence that under other conditions, human beings will cheat and exploit others who *are* their genetic relatives, and that once some members of a group or community start to renege on social contracts it is the behaviour of those who do so which the others will increasingly imitate. Particularly in large groups whose members are not genetically related, it is not at all easy to see how altruism can become the evolutionarily stable strategy uninvadable by defectors who will be imitated in preference to the altruists. So under what conditions can Blackmore confidently predict that altruistic strategies will be sufficiently widely imitated that they will come to dominate selfish ones (both being, presumably, 'meme-driven')? There is by now an extensive literature on this, much of it grounded in evolutionary game theory, including not merely formal models but field-studies and social-psychological experiments. It

would be unreasonable to expect Blackmore to cover it in a single chapter of a short book which has in any case been written more as a manifesto than an encyclopedia. But the implication that it can all be absorbed in, or has been overtaken by, a 'memetic theory of altruism' whose 'main assumption is that people preferentially copy the people they like' may well leave the authors of that literature somewhat underwhelmed.

About religion, where sociobiology has the hardest time linking 'meme-driven' behaviour to inclusive reproductive fitness, Blackmore is on firmer ground. It is altogether more plausible to suppose that religious memes are replicated and diffused because of their selective function at the level of the group than because their carriers are individually more likely to have more children (although there are, admittedly, some well-documented religious communities where this does hold good). Instructions affecting phenotype which are underwritten by beliefs in supernatural sanctions, are encoded in sacred books, and enjoin the performance of elaborate ceremonies may well give the group a competitive advantage over other groups and thus enhance the probability of replication of memes carried by its members relative to theirs. Moreover, it may well do so by at the same time reinforcing altruism within the group through a mixture of punishments and rewards and permitting or even encouraging deceit, manipulation and aggression in relationships with the members of other groups.

Blackmore seems inclined to regard all religions as 'memetically selected' bundles of 'clever tricks' which fool people into believing things which are either untestable or false (as, let us remind ourselves, science often does, too). But this is to ignore the distinction between genuine conversion and mere 'adhesion', as Arthur Darby Nock called it. No doubt religions have often been helped in their quest for converts by apparently successful prophecies, answers to prayer and miraculous interventions in the natural course of events. But for many of its (mere) adherents, religion is not a matter of intellectual commitment so much as emotional involvement in the mourning of the dead, the celebration of victory, the re-enactment of myth, the collective expression of hope or fear, and the symbolising through rites of passage of transition from one stage of life to the next. If 'memetics' is to contribute anything significant to what is already well known to anthropologists, sociologists and historians of religion, it will have to be by identifying specific components of different religious 'memeplexes' whose probability of replication can be shown to have been enhanced by specific features of their carriers' environment - a rewarding task, but a very difficult one.

When it comes to self-consciousness, Blackmore appears to assume that her readers will all be unreconstructed Cartesian dualists still clinging to what Gilbert Ryle famously called the 'ghost in the machine'. But how does 'memetics' resolve the disjunction between the acknowledged findings of psychology and brain science on the one hand and the persistent phenomenological sense of self on the other? For Blackmore, the sense of self is another 'clever trick', which works because the various memes by which we are 'bombarded' can, once they get into our heads, 'gain an advantage by becoming associated with a person's self concept'. But if our sense of self, illusory as it may be, is intrinsic to any and all our beliefs, values and preferences, how does it influence the relative probability of replication of some memes as against others? On a 'memetic' view, competition between memes is what drives the various cultures between which the human species is distributed down one rather than another evolutionary pathway. But what actually happens in a culture where anti-Cartesian memes propagated by psychologists and philosophers

start to invade minds in which what Blackmore calls the 'selfplex' has previously been undisturbed? If memes 'associated with a person's self concept' have, on average, an advantage, are anti-Cartesian memes a mutation doomed to extinction? Or will they somehow combine with the memes constitutive of our phenomenologically unreconstructed beliefs, values and preferences in such a way as to be replicated along with them? And if they do, what difference will it make to which of the bundles of instructions by which our cultural behaviour is directed? Will we cook soups, build churches, wear hats, perform plays or give birthday parties any differently as a result?

Despite these reservations, nothing in this review is meant to imply that Blackmore's emphasis on the significance of imitation in cultural evolution is necessarily misplaced. The relation of imitation to individual learning is itself a matter of some dispute. But the acquisition of an entire repertory of cultural behaviour by individual trial-and-error would be prohibitively costly, and the human capacity to absorb and retain rules of conduct observed in the behaviour of other people goes far beyond what could ever be achieved by operant conditioning and stimulus enhancement alone. On the other hand 'socialisation', so called, is not just a matter of children doing what they see their elders doing. It is also a matter of their doing what their elders tell them to do even if the elders don't even pretend to do it themselves: 'don't do what I do, do what I say!' And what about cultural behaviour which is the result not of imitation or learning but of enforced obedience to instructions from lawgivers and other people in positions not merely of influence but of power?

It may be that I am here disclosing a professional bias, since I am not a psychologist or anthropologist but a historical and comparative sociologist more at home in topics like class conflict, the formation of states and the displacement of slavery by wage-labour. But there is more to cultural evolution than just the relative psychological attraction of different memes. Blackmore sweepingly asserts that 'social scientists study the way that people's lives and selves are constructed by their roles, and by the texts in which they are embedded. But they have no evolutionary theory within which to understand the processes going on.' That, however, is simply not so. I am not the only sociologist in the world who sees social roles as part of the same continuous evolutionary process out of which first genes and then memes have emerged and which stretches all the way from the chemical evolution of the nucleic acids to 'intelligent' machines. But social roles involve a further mode of information transfer affecting phenotype. As well as instructions transmitted genetically by inheritance and instructions transmitted memetically by imitation and learning, there are instructions encoded in formal rules underwritten by institutional inducements and sanctions which define the practices that make our roles what they are; about these Blackmore has little or nothing to say.

How successful, then, is *The Meme Machine* likely to be as, under Blackmore's definition, a meme designed to further the replication and diffusion of the 'meme' meme? The answer, I suspect, is that it is unlikely to do for public understanding of the meme-centred approach to cultural selection what Dawkins's *The Selfish Gene* has done for the public understanding of the gene-centred approach to natural selection. This isn't just because Blackmore doesn't have Dawkins's altogether exceptional gift for accurate synthesis and lucid exposition. It is because she attempts too much too soon. No author of a book like this one can yet draw on the large volume of well-tested hypotheses and closely-documented examples available to writers on

biological theory. Only detailed and wide-ranging re-examination of the relevant ethnographic, historical and archaeological evidence for the heritable variation and competitive selection of clearly identifiable 'memes' whose spread can accurately be traced and functions convincingly specified will turn 'memetics' from a project into a science.

Abstract

The process of design in architecture parallels analogous generative processes in biology and the natural sciences. This paper examines how the ideas of Darwinian selection might apply to architecture. Design selects from among randomly-generated options in the mind of the architect. Multiple stages of selection generate a design that reflects the set of selection criteria used. The goal of most traditional architecture is to adapt a design to human physical and psychological needs. At the same time, however, a particular style of architecture represents a group of visual memes that are copied for as long as that style remains in favor. Darwinian selection also explains why non-adaptive minimalist forms of the modernist style have been so successful at proliferating. The reason is because they act like simple biological entities such as viruses, which replicate much faster than do more complex life forms. Simple visual memes thus parasitize the ordered complexity of the built environment.

Keywords: adaptivity, architecture, Darwinian process, design, images, memes, minimalism, modernism, parasitic, selection, styles, viruses.

1 Introduction

The world of the architect is created in an architect's mind according to certain principles related to the biology of the brain. According to one theory of the thinking process, an idea arises out of the competition among similar and dissimilar ideas occurring simultaneously in adjacent neural circuits of the brain [6; 7]. The same principles of competition and selection might be said to apply to the general public in accepting architecture. Things in the built environment originate and endure (not just in the tectonic sense, but in their survival value in a society's common language) because they 'make sense' in some way. Competing ideas in a society eventually suppress or reinforce each other to produce one or more dominant themes. In other words, creativity and survival work in ways that are compatible with the cognitive machineries that make up the mind.

Nevertheless, sometimes the mind works against the body by acting in a harmful manner. An architect's mind has the power to either create designs that adapt to human needs and emotions, or to impose arbitrary images on the environment. A Darwinian selection process in architecture takes place among competing ideas in the mind. A second process, also Darwinian, occurs in the society of consumers. This second selection process is between styles, where certain styles win over others. In both of these selection processes (i.e., in the mind, and in society), the criteria are a mixture of human needs and irrelevant stylistic fashions. Meme propagation and encapsulation explain why these two disparate sets of selection criteria can coexist, and when one set can displace the other.

This paper applies the theory of memes to the field of architecture. Two main points are argued: (1) Darwinian processes (combining variation and selection) are important to architecture; and (2) the specific case of modernist architecture corresponds to a 'parasitic' meme, which has spread in spite of its being non-adaptive for the people that make use of modernist buildings. These two theses are logically independent, though both are necessary to present a picture of how architectural styles propagate. The first thesis may seem rather obvious to many readers, yet it has important implications for the design process in general. The second thesis is more controversial, and is discussed in greater depth. Explaining the unlikely success of modernism by other than subjective criteria is our eventual goal.

Design is a problem-solving activity. Human intelligence allows both the generation of possible alternative solutions and selection among them to take place mentally. That neatly summarizes our intellectual advantage over other animals: our imagination is a profoundly useful virtual reality simulator. A more intelligent system will have a more efficient mental representation and selection process. The architect's mind is impacted by the problem space and various 'memes' (conceptual entities that propagate among human minds) from a variety of sources [14]. These could come from one's own memory; visual templates from the environment; the influence of other architects; etc. Competing forces such as engineering constraints, a desire for creativity, and the unique need to express oneself drive the design to its final state.

A Darwinian process in the mind of the designer depends on a set of selection criteria. Traditional societies such as pre-industrialized people, and the industrialized nations up to and including the nineteenth century used a wide range of selection criteria that, among other practical constraints, enhance emotional well-being for the user. Specific architectural styles, however, replace the selection criteria of traditional adaptive design by a matching to visual templates, or 'memes'. Once adaptive design is abandoned, the spread of architectural styles depends strictly on factors governing meme propagation in a society. A minimalist style then possesses an unbeatable advantage over more complex styles, because of its low information content. It is possible to explain in this fashion an important event in the evolution of mankind: the drastic change in the visual character of the built environment during the twentieth century.

The successful spreading of modernist design is interpreted in terms of the replication of memes. After a design style is introduced and is accepted for whatever reasons by a group of people, then it is subject to Darwinian selection from among the pool of competing styles. This is where consumers, the construction industry, and the architectural establishment come into play by exerting selection forces. A second selection occurs entirely outside the architect's mind, within

the arena of human society [13]. Some architectural styles die out, whereas others survive and become popular. Their success has little to do with their fitness for human habitation; the criteria for success in Darwinian selection are abstract and are not based directly on human needs, even though it is human beings that do the selecting.

Studying how architectural memes spread in a society, and how competing memes are selected requires a knowledge of the factors affecting meme propagation. Francis Heylighen has identified a list of these. We will discuss seven of his factors: SIMPLICITY, NOVELTY, UTILITY, FORMALITY, AUTHORITY, PUBLICITY, and CONFORMITY in the context of architecture [17; 18]. With the exception of UTILITY, none of these factors serves actual human needs. We will argue, therefore, that the spread of a design style occurs in a society more because of mass media than for practical reasons. Even UTILITY will be shown to obey memetic transmission, as often the mere *promise* of UTILITY is responsible for the success of an architectural style that creates buildings impractical in actual use.

We will propose an eighth factor that aids meme propagation: ENCAPSULATION describes how memes link with other memes. This process confers an advantage to the encapsulated meme because: (a) it increases the meme's virulence by making it appear more attractive; and (b) it protects the meme from external challenges by insulating it inside a complex of other, beneficial memes. An encapsulated architectural meme manipulates our emotions in order to propagate. ENCAPSULATION embeds a meme or collection of memes into a meaning structure [22]. Through this mechanism, visual memes acquire an emotional and physical basis. At that point, they cease to be regarded as mere ideas open to debate, but assume the fundamental character of beliefs defining one's consciousness.

It is also possible to condemn an architectural style by deliberately encapsulating it within a shell of negative associations. By using ENCAPSULATION as a weapon to discredit competing styles, a useful idea can be tainted (whether there is any basis for that association or not). A society's collective unconscious from that point on automatically rejects such an idea or style without question, even though it may offer excellent solutions to urgent problems. In contemporary architecture, destructive encapsulation is used to discredit new buildings in the Classical and Nineteenth-century styles. This has happened despite the fact that earlier buildings in those styles are among the most comfortable and best adapted to human needs. We will argue that by encapsulating them with pathological memes, those styles have effectively been placed in quarantine.

Success in the spread of social memes is measured by how far they establish themselves as basic beliefs in a society. This paper explains their spread from the point of view of Darwinian processes. A group of memes achieves its greatest success when it becomes part of the establishment; i.e., it is institutionalized. We are first going to deal with those factors that increase the spread of memes, and thereby help in their chances for institutionalization. In the final section, we explain how once memes have been institutionalized they acquire a rigidity that makes them extremely difficult to remove. The institutional perspective offers some strong explanations for the remarkable persistence of modernist architecture and urbanism in spite of their negative aspects.

2 The modernist style and military architecture

The modernist style of architecture, otherwise called the *International Style*, has been the overriding building style from the 1920s until now. The style is instantly recognizable by its geometry of cubes and rectangular slabs; flat plain surfaces; the lack of thick connective boundaries; the use of steel, glass planes, and concrete panels; and in many cases the elimination of color and structure on the human range of scales 1mm-1m [23]. Representative buildings and architects include the *Bauhaus building* (1926) by Walter Gropius; the *Pavillon Suisse, Cité Universitaire* (1932) and *Carpenter Center for the Visual Arts* (1961) by Le Corbusier; the *Casa del Fascio* (1936) by Giuseppe Terragni; the *UN Headquarters* (1950) by Wallace Harrison and Max Abramovitz; the *Seagram building* (1958) and the *Neue Nationalgalerie* (1968) by Ludwig Mies van der Rohe; and the *National Theatre* (1967) by Denys Lasdun.

Modernists claim their buildings to be 'functional'. Nevertheless, simply looking like a machine from the 1920s doesn't guarantee functionality in a building. Those machines were housed in smooth metal shells, following cubist aesthetic principles, so their 'look' had nothing to do with their function: it merely conformed to a passing artistic fad. A culture that substitutes images for the real thing risks losing its accumulated knowledge. Many authors claim that this has already happened, since our generation has lost innumerable adaptive architectural traditions stretching back several millennia. More recently, 'high-tech' has become the fashionable international style of corporate architecture, simply because its superficial appearance of metal pipes, glass, mirrors, and plexiglass links it to modern technology; this goes on despite high-tech's extremely high cost and low user comfort. Representative high-tech buildings and architects include the *Centre Pompidou* (1977) by Richard Rogers and Renzo Piano, and the *Hong Kong and Shanghai Bank* (1986) by Norman Foster.

Two contradictory movements in twentieth-century architecture work against adaptive selection towards the human needs of users. The first is an attitude taught in recent decades by our schools: that an architect has artistic license to ignore certain practical constraints — indeed, that it is necessary to do so — in the pursuit of a 'great work of art'. The second is a standardized approach to buildings, behind which is a conviction that shaping design to particular individual needs is simply being self-indulgent and therefore socially irresponsible. Early modernists set up standards for minimal dwellings that had little relation with the living needs of real human beings, and incredibly, most of them are still applied today. A central idea in German social housing of the 1920s, the *Existenzminimum* [4] codified the minimum space in which a German blue-collar worker and his family could be housed. That is where oppressively low ceilings and cramped, tiny kitchens in today's apartments originate.

Although traditional architecture for human use adapts to human needs and sensibilities, military architecture is the exception. A well-defined typology has been used throughout the ages to construct deliberately uncomfortable environments. These include defense installations and castles (experienced from the outside), and dungeons, prisons, crematoria, etc. (experienced from the inside). Such environments lack texture, color, and decoration, preferring damp, grey surfaces that are usually punishing for human beings. Their forms and surfaces are meant to oppress and frighten us: they communicate danger and evil directly through architecture. Where possible, a grandiose scale dwarfs the role of a human being in the environment. To achieve a

forbidding, hostile exterior, a building must reveal a minimum of information. This makes sense when defensive fortifications protect against attack by infantry.

There are obvious stylistic similarities between military and modernist architectures, since many modernist buildings look forbidding, ominous, stark, alien, faceless, and present a generally hostile appearance. The reason for this impression is that they utilize some of the same typology from military and prison architecture. Here we face a paradox: how could society select an architectural style for human use that has a similar typology as the military style, which was developed specifically to make people feel uncomfortable? Our explanation is that modernist architecture is a 'parasitic' meme group that is non-adaptive to human use and sensibilities. At the same time, however, the group of memes defining the modernist style of architecture has memetic advantages that helped it to take over. It is for this reason that modernism won out over competing styles.

3 Design as a Darwinian process

Design ought to begin by understanding a building's particular uses. A designer is aided by recalling built examples that work under similar circumstances; this is the idea behind Alexandrine Patterns, which distill working solutions from widely different cases [1]. Alexander *et. al.*'s *A Pattern Language* provides a collection of design constraints extracted from traditional architecture the world over that are meant to anchor and guide an emerging design [24]. These aim to make the designed structure adaptive to human needs, while leaving the form and visual aspect unspecified. It really doesn't matter what triggers one's creativity, as long as the generated alternatives cover a broad enough range, and the selection is adaptive. The possibilities of a Darwinian process of design are tied to the system of options within which it operates, and the richer the system is, the broader the field.

Each design competes in the mind of the designer with other conceived possibilities, and the fittest ones (those that partially solve the problem as posed) survive to the next generation. More detailed designs generate further alternatives, which are culled by selection in the subsequent round. The cycle starts with the creation of variants, which then get culled by using a set of selection criteria; the survivors are used to create a new generation of variants, which get culled in turn; and so on. This represents a typical Darwinian process [6; 7; 8]. Visual inspiration can fix the entire gestalt of a project in a single initial image. Often, it is precisely such a *conceived* image that, through the emotional feedback it generates in the mind of the architect, sustains the design and drives it towards completion.

When architects turn for inspiration to fixed images from a set vocabulary defining a style, images displace the adaptive component of design by changing the selection criteria. Design then becomes a process of comparison with certain visual stereotypes, which radically affects the end product. Matching to currently popular images takes priority over all the other design constraints. The new selection criteria may not aim at adapting a design to human needs. The selection process itself ceases to be recursive because selection occurs only on the first level, which is derivative of memory and stored images. If structural, functional, and practical constraints are abandoned in the interest of maintaining images, however, such a design method acquires advantages of economy over more complex approaches that are adaptive.

By accepting input from natural objects (e.g., Le Corbusier from a crab shell he found on the beach and later used to model the Pilgrimage Chapel *Notre-Dame-du-Haut* at Ronchamp); man-made artifacts; buildings originally intended for another use (e.g., the fascination of Walter Gropius and Le Corbusier with American grain silos); modernist architects chose not to follow an adaptive process for turning their inspiration into a practical design. Copying an image is very easy to do and gives a superficial sense of understanding while ignoring the complexities of both the copied structure, and the needs of what is being designed. Grain silos were the end-result of adaptive design for agricultural storage, not for habitations. Copying the 'look' of a structure developed for something else, and applying it to a use for which it was never intended, is not adaptive. A crab shell is beautifully adapted to house a crab, but not for its magnified shape to house human beings wishing to worship in a church.

4 Memes and architecture

The word 'meme' denotes any idea that endures and propagates [5; 11; 12; 14]. Memes have a lifetime; they can 'die' when they cease to be of interest to the population for whatever reason. If memes die, then in a given collection of them, one can speak of the survival of some, and the death of others. Survival in an environment, coupled to forces that promote mutation and change leads to Darwinian selection. The concept of memes thus has explanatory value. It also has heuristic value because it forces us to examine how ideas persist and propagate. An image will stick in memory if it is encapsulated in a meaning structure. An image will be more likely to be transmitted to others if it is easy to remember, among other factors to be discussed below.

While our topic is architecture, it is instructive to discuss for a moment a parallel situation in biology where these ideas are routinely useful. In considering how microbes attack tissue, as for example those in the oral cavity that cause tooth decay, the scientist studies the tendency of a microbe to adhere to the tooth surface. Microbes that have the greatest stickiness are also likely to have the greatest virulence; i.e., cause the most serious disease. The logic is straightforward: the stickier the microbe, the greater the number that will adhere to the tooth at any one time. Research shows that the surface of tooth enamel has a certain chemical structure, and the virulent microbes have a corresponding chemical structure that binds to it; rather like the two mating surfaces of Velcro.

Individual memes, or images, are the equivalent of agents that 'infect' memory. Each image has a set of attributes that makes it more or less likely to stick in memory and to be transmitted to others. In the universe of Art and Design this mechanism is readily apparent. The volatility of design themes drives the world of fashion, where the business and sales force creates a strong pressure for selection that is Darwinian at its core. New mutations arise with regularity, and these are tested against the environmental forces in which they appear. The life and death cycle can be swift for unsuccessful fashion styles. The same is true in architecture, where there is an undeniable and changing 'fashion'. Nevertheless, a fashion arrests the adaptive design process, in which selection evolves specific solutions to individual problems that are exquisitely suited for their job and surroundings [24].

Architectural memes are more nearly analogous to physical replicating entities such as viruses, than to more general memes representing only ideas. The reason is that the former are encoded

as actual structures (other than neuronal circuits). It is only their replication that occurs through memetic transmission; the artifact in this instance has a physical existence outside the human mind. An architectural style thus exists in two very different forms: (i) as an ideology codified in books and taught as a tradition in architecture schools, which perpetuates a group of memes in people's brains; and (ii) as images represented in the built environment. Each aspect reinforces the other. The built environment serves as a source of continuous re-infection by visual architectural memes. The image/building/image cycle has positive feedback, and can lead to an exponential rate of infection.

While architecture is often classed along with music, poetry, and the fine arts as a vehicle for individual artistic expression, it is actually far more than that. Humanity needs to house itself, and architecture represents a world-wide building industry that is forever looking for prototypes to copy. The vast majority of buildings, be they commercial or vernacular, require a typology of reproducible patterns. Clearly, the process by which architectural styles spread through copying is one that lends itself to a memetic explanation. This is seen in practice, where throughout history, a single example was often sufficient to establish a new style of architecture. Even though the early buildings defining a new style could number only a handful, their true impact lies in their easy repeatability. Conversely, a style that is difficult to reproduce will die out. The style succeeds not because its original examples are either attractive or useful, but because it infects the vernacular building tradition.

5 Explaining the unlikely success of Modernism

In 1922, Le Corbusier exhibited a series of drawings labeled "A Contemporary City" at the *Salon d'Automne* in Paris; he built the *Pavillon de l'Esprit Nouveau* for the International Exposition of Modern Decorative and Industrial Arts, held in Paris in 1925; Walter Gropius built the *Bauhaus building* in Dessau in 1926 as a visual example; Ludwig Mies van der Rohe organized and contributed to the mass housing projects for the Stuttgart *Weissenhoffsiedlung* in 1927, which consisted of very similar white, rectilinear, flat-roofed temporary and permanent buildings. All of those buildings and drawings provided images for young architects to copy. The reason anyone would even consider such plain prototypes was the promise of inexpensive housing for all made possible by modular design, bolstered by proclamations of links to a 'new' society.

The rate of transmission of a visual style among human minds depends on several factors. Considered simply as information, the success of an architectural style is governed by the speed at which the associated memes can propagate. The situation is akin to percolation or diffusion: copies of an object (a piece of information encoding the style) have to pass from one human mind to another. This resembles the mechanism by which infectious agents spread in a population. Individuals in the population have little control over the process. Propagating agents are obviously not selected by the host, since they parasitize their more complex hosts. The process is infection rather than competition. An epidemic occurs when a virus has evolved an unbeatable advantage over its hosts.

Francis Heylighen has identified factors contributing to meme propagation [17; 18]. The meme could be an image, or a set of rules defining an architectural style. We will examine four factors now: SIMPLICITY, NOVELTY, UTILITY and FORMALITY are relevant for the initial spread

of modernism, and three more of Heylighen's factors help in the institutionalization of modernism (there are other factors that are not discussed). One of Heylighen's criteria is SIMPLICITY. A simple idea is easier to reproduce and has a competitive edge over ideas that are more difficult to grasp; it poses a lesser burden on our cognitive system [18]. Therefore, an architectural style that is simpler to encode will propagate more successfully than one that is difficult to encode. In an analogy with life forms, viruses reproduce much faster than more complex organisms because of a reduced structural investment. Biological and computer viruses take advantage of their host's structural complexity, using it to propagate themselves, and without which they could never replicate at all.

The early modernists introduced images of geometrical emptiness with enormous replicative power. The modernist vocabulary of plain, featureless surfaces in a flat geometry of cubes and rectangles eliminates substructure; eliminates borders; eliminates contrast and color in design by using only plain white or gray; and finally, tries to eliminate the building material itself through its replacement by glass panes [23]. We see some or all of these features used in a majority of buildings throughout the second half of the twentieth century. Design richness and complexity in other architectural styles was eliminated in the drive to reach forms with minimal information content. Architects in the 1920s working in a traditional style originally dismissed this effort as perverse and not worthy of notice; they little realized that it satisfied the SIMPLICITY criterion for memetic propagation.

Another criterion is NOVELTY, where standing out and thereby attracting one's attention facilitates a meme's assimilation. New, unusual, or unexpected ideas arouse one's curiosity [18]. Twentieth-century architecture used novelty of a deliberately shocking kind. The early modernist prototypes looked strange to people used to Nineteenth-century architecture. Indeed, the modernist style is arrived at by reversing elements of previous traditional styles [23]. The spread of those novel images occurred primarily through the media before any significant number of examples was actually built. Le Corbusier was remarkably successful at propagating modernist memes through the journal *L'Esprit Nouveau*, which he controlled [9]. That was the age when picture magazines became a popular medium for visual information, helped by technical advances in photography, printing, and distribution. People were eager to read about new ideas, especially if they were accompanied by futuristic-looking illustrations.

UTILITY plays a double role here. First, the architectural media declare (without justification) that a minimalist structure is somehow more efficient or is better adapted to the functions it is supposed to house. The opposite is true: many modernist buildings are dysfunctional because their imposed form and impractical materials hinder human activities. Criticisms of modernist buildings and their materials include the impossibility of effective temperature control in a glass-walled structure; the tremendous energy waste in attempting to do that in a sealed building; the 'sick building' syndrome; the social damage of living in skyscrapers (most severe for children and the elderly); the dangerous wind shear created on the ground by smooth-faced skyscrapers; flat roofs that invariably leak; the staining or cracking of large, plain surfaces; a general problem of joints when connective interfaces are eliminated in the interests of style; psychological alienation produced by dead gray surfaces and concrete slabs, which give an unpleasant 'hard' echo; etc. [3]. Still, the mere *promise* of UTILITY is often enough for propagating spurious ideas [18].

Second, the modernist style represents a genuine advantage for the construction industry that can build cheap, minimalist box-like structures without having to worry much about either structural quality, or accommodating human physiological and psychological needs [2]. A visually simplistic architectural style thus offers a commercial benefit via UTILITY that counts as a major factor in its propagation. Modernist memes found a ready environment after the Second World War, when buildings had to be produced in large numbers and at low cost. Never before in history had such building efforts taken place. This was also in the period that the industrialization process was at full speed, penetrating more and more economic sectors of society. The construction industry eagerly embraced the UTILITY offered by modernist memes. Philip Johnson (the first American architect to convert to modernism) frankly admitted that: "*The International Style did sweep the world because it came along at the same time developers wanted to make cheap buildings, and this was cheaper than other architectures*" [19].

Yet another factor is FORMALITY: the more formally an idea is expressed, the more likely it survives in transmission [17; 18]. The intention of modernist design is to be context-independent. Adaptation requires selection on the basis of local climate, materials, culture, and relationship to adjoining buildings and specific human needs. Since its inception, however, modernism has been 'universal' because it is based on a small set of simple images. Different individuals in different contexts can interpret modernist rules in the same way. A modernist building can be put up anywhere in a city, anywhere in the world, because the style is independent of locality or particular circumstances. Materials of choice are pre-formed panels, glass, steel, and reinforced concrete; these are industrial materials that are detached from any region. Modernism imposed the universal visual language of abstract cubism to come up with "*one single building for all nations and climates*" [3].

Non-adaptivity to human needs, which helps in memetic propagation, is rooted in modernist ideology. The philosophical origins of modernism in Germany of the 1920s reveal a parallel between modernism and totalitarianism [25]. The German art historian Wilhelm Pinder (a supporter of Hitler) and his student Nikolaus Pevsner (an architectural historian who was one of the strongest promoters of modernism as a guide for social and political ideals) argued that great architecture is the product of the *Volk*, during periods when ideology triumphs. Adolf Hitler, Josef Goebbels, Walter Gropius, and Ludwig Mies van der Rohe all shared the conviction that architecture was an expression of the central spirit of an epoch, and thus justified idealism, absolutism, and arrogance [25]. In this view of the world, the individual is insignificant, and the needs of the human user are thus of little consequence [25]. Philip Johnson complained of the futility of trying to discuss the aesthetics of modernism with Walter Gropius: "*Talking to Gropius was a dead end because he would still mouth the Giedionesque platitudes of social discipline and revolution*" [9].

6 Competition among early twentieth-century architectural styles

The unbiased human mind applies selection criteria that give the most positive emotional feedback from a built structure. This is something we have evolved to do: we instinctively avoid pain and discomfort and seek pleasure. If a design (and, by extension, the building when finished) provides joy to the architect, then one can expect the user to share that experience. The same does not follow, however, when purely intellectual selection criteria replace those based on

emotions. What one person believes in ideologically is not necessarily shared by others. Modernism was very successful at convincing people to forgo sensual pleasure from built forms, as minimal surfaces and spaces offer less visual stimulation than human neurophysiology is built to handle [22]. Memes help us to understand why architectural styles that give emotional satisfaction were replaced by those that don't.

Once built, structures survive or not according to Darwinian selection. Here we are no longer talking about Darwinian processes in the mind of the architect, but survival in the outside world. Occasionally buildings get destroyed by natural or human acts; most often conscious decisions are made on whether to repair the inevitable wear in an existing building, or to build a new building altogether in its place. In biology, the survival rule for a species is to procreate before death. Culling of organisms is determined by survival in the environment. In architecture, survival of a particular style depends on whether the buildings representing that style are preserved, or are replaced by those of another style. Architectural survival therefore depends upon decisions that are heavily influenced by stylistic concerns.

Different styles competed with each other at the beginning of the twentieth century. Any architectural style that contained traditional elements was doomed to extinction because people now demanded NOVELTY. Styles that had comparable NOVELTY were further selected on the basis of SIMPLICITY, UTILITY, and FORMALITY. Art Nouveau is very high in information content. The convolutions, curves, and complex colors on which the style depends ought not to propagate rapidly, and that's exactly what happened. Despite an initial flourish, Art Nouveau didn't last for more than about a decade. Its markedly plainer successor, Expressionism, was equally short-lived because of its curvature. Art Deco abandoned the curves of Art Nouveau and Expressionism, adopting a more rectangular geometry, and was much longer-lived. One could surmise that, by lowering its information content, it acquired greater staying power. Finally, Modernism got rid of the visual richness of Art Deco, reducing its information to an absolute minimum; it won out over its competitors by spreading around the world and surviving until today. These events in architectural history support a memetic theory of architectural styles, with selection on the basis of SIMPLICITY.

Looking at both UTILITY and FORMALITY leads to the same conclusion. Unless there is a strong societal demand for information-rich buildings and environments, the construction industry will select those that are visually plain (since they are often cheaper to build, though not to maintain). As far as FORMALITY is concerned, a set of context-independent rules was never given for either Art Nouveau or Art Deco. We have no formal set of symbols that can generate an Art Nouveau building. The style depended upon the individual creative genius of say, Louis Sullivan or Victor Horta, who drew their inspiration freshly from each new architectural context. It is worthwhile noting that a highly successful style in architectural history, the Classical Style, also depends on rather precise formal rules that can be applied in any situation regardless of context. Nevertheless, its much higher complexity compared to modernism allows adaptive design.

A large number of Art Nouveau and Art Deco buildings were built in the early decades of the twentieth century, before the modernist selection criteria took hold. Many of those buildings did not survive, precisely because the selection criteria used in the 1960s for preserving buildings

were the same as those for designing new buildings. The stereotyped visual template of a glass box determined which buildings to save from demolition, and those buildings that did not match were destroyed. In effect, structures were categorized according to modernist images, thus providing a mandate to eliminate those judged to be 'misfits' One reads that the architecture of the twentieth century is founded on rational laws as opposed to base emotions, which is quite true. Nevertheless, this statement ignores the incredible persistence of modernist memes, which is fundamentally emotion-based. This emotional dimension of memetic transmission will be discussed next.

7 Encapsulation of images in the mind

Entities with a finite lifetime will survive in the sense of propagating their information only if they are favored by selection forces. An encapsulating shell that surrounds a meme by an attractive verbal explanation endows it with a meaning system that helps in transmission. Once inside a mind, a meme will lose its boundaries as it is sacrificed to a larger meaning structure that is expressed as a physical grouping of neurons. The mind shows itself to be a multiply-connected network, where ideas, opinions, factual knowledge, and prejudices are all interlinked into what may be called one's 'consciousness' [16; 22]. In this way, memes influence an individual's thoughts and actions. This is the idea behind advertising: embedding a commercial product into a person's consciousness will guarantee the use or purchase of that particular product as the result of a subconscious decision [5].

Architecture and advertising act in much the same way. After they are taught in Architecture school, the memes of an approved style become a permanent part of one's thinking patterns. They are encapsulated into meaning structures such as metaphors. The group of neuronal circuits consisting of images, their encapsulation, and their interconnections defines some domain of one's consciousness. Those regions of the brain provide bases for meaning structures, which are used to interpret the world throughout one's life [16; 22]. We are thus programmed to automatically replicate memes whether or not they are good or useful; that's because they are part of a person's inner belief system [5]. This also explains why visual icons can rarely be dislodged by scientific arguments. A simple but irrational belief can displace an accurate but more difficult description of the world.

This section proposes another factor affecting meme propagation: ENCAPSULATION. A meme boosts its virulence by linking itself to other attractive memes, which then shield the original meme. (This is related to but distinct from Heylighen's criterion of COHERENCE, wherein the assimilation of new ideas depends on their being consistent with existing knowledge [17; 18]). The advertising industry is founded upon techniques of encapsulation: either physical packaging, or the packaging of products within ideas. A commercial product sells just as much because of an attractive package as for any other factor. An effective marketing strategy links a product via emotional appeals to self-esteem, sex, status, power, individuality, etc. It is not a coincidence that modern advertising techniques developed alongside modernist design, and early modernist architects showed a keen interest in psychological manipulation as it was then being incorporated into the advertising industry [9]. Le Corbusier actually made a living from mass media and commercial promotion independently of his work as an architect [9].

This concept applied to architecture reveals an unexpected yet major reason for why architectural design evolves the way it does. A change in encapsulation comes from societal discontinuities, which affect architecture just as much as practical matters such as the introduction of new materials and novel methods of construction. For example, immensely powerful social forces unleashed between the two world wars led people to adopt modernist design memes as a reaction to class oppression. They identified decorated buildings as visual symbols of what was wrong with the past. With all the old values discredited by the horrors of the First World War, people eagerly embraced new ideas, thus linking desirable social aims to encapsulated memes. They willingly sacrificed pleasure from their surroundings for the promise of a better future. The *1918 Manifesto* of the Dutch group of modernist architects known as "De Stijl" states [10]:

"The war is destroying the old world with its content ... The new art has brought to light that which is contained in the new consciousness of the age ... Tradition, dogmas and the predominance of the individual stand in the way of this realization. Therefore the founders of the new culture call upon all who believe in reform of art and culture to destroy those obstacles to development ... The artists of today, all over the world, impelled by one and the same consciousness, have taken part on the spiritual plane in the world war against the domination of individualism, of arbitrariness."

Bruno Taut, a key member of the German group of modernist architects, had this to say in his *Frühlicht* of 1920 [10]:

"Oh, our concepts: space, home, style! Ugh, how these concepts stink! Destroy them, put an end to them! Let nothing remain! Chase away their schools, let the professorial wigs fly, we'll play catch with them. Blast, blast! Let the dusty, matted, gummed-up world of concepts, ideologies and systems feel our cold north wind! Death to the concept-lice! Death to everything stuffy! Death to everything called title, dignity, authority! Down with everything serious!"

These extracts give an indication of the rage against traditional styles in art and architecture prevalent at that time. They reveal the profound societal discontinuity that was to provide a breeding-ground for any ideology, mixing political as well as artistic memes, which promised radically new solutions to the problems facing mankind.

A biological virus remains infectious against the continuous development of antibodies by host organisms. The way it does this is to change its encapsulation so that it is no longer recognized by the host. This is said to be one of the mechanisms for the resistance of the HIV virus to therapy [20]. In exactly this fashion, modernism successfully changes the shell in which its memes are packaged. Modernist ideologues accomplish this switch with great dexterity: almost a sleight-of-hand. As soon as one of the encapsulations is identified, and it is realized that it does not lead to the promised benefit, the shell is changed to a new one. The central core — containing images that erase information and complexity from the environment — remains the same. We list seven encapsulations for modernist memes:

- (i) 'Progress and economic prosperity from technology';
- (ii) 'Freedom from class oppression through new design';

- (iii) 'Social equality and housing opportunities for all';
- (iv) 'Moral superiority from using honest materials that express the spirit of the age';
- (v) 'Improved health and hygiene through smooth surfaces';
- (vi) 'The mathematical principles of pure form';
- (vii) 'Cost benefits resulting from modular production'.

Today, the modernist style predominates in architectural practice, and is taught in our schools to the exclusion of most other styles; the above encapsulations are therefore presented and discussed at length as part of the standard architectural literature. It is not useful to repeat that material here. What is of immediate interest is that the seven slogans listed above are very successful at encapsulating modernist memes, thus helping their propagation. Our point is that, in the absence of either a scientific or sensory basis, modernist architecture justifies itself solely by its memetic encapsulations. For detailed criticisms of the unfounded claims of modernism and the weakness of the usual arguments trying to justify those encapsulations, see [1; 3; 23; 24].

An architectural meme that has become part of our meaning system is protected by its ENCAPSULATION. Attempting to revise the meme pulls at the entire meme complex, which is attached to the rest of the mind's associational network of concepts. Writings by modernism's proponents link the visual images representing the style to other, beneficial memes, so that questioning modernist design appears to question the technological, scientific, economic, and social progress of the twentieth century. This often triggers a strong emotional reaction that is reminiscent of religious intensity [25]. We suspect that certain memes such as these become encapsulated into our belief systems in places traditionally occupied by a religious credo. From the first author's experience, this impression is reinforced by the irrational manner in which contemporary architects engage in discussing the foundations of their discipline.

When confronted by criticism based on scientific reasoning, many architects react by interpreting everything in modernist terms: they base all arguments on what the modernist 'masters' said, as if that were some sort of revealed truth. This is indicative of religious fundamentalism. An automatic reliance on modernist dogma as part of one's basic belief system is consistent with a memetic infection; i.e., the justification for a belief is the infecting meme itself. It is pointless to argue against ideas and values that people accept unquestioningly, or have adopted in the struggle to better their lives [5]. The reason is that people are physically, viscerally, and emotionally attached to their beliefs, regardless of how they acquired them, and irrespective of their absolute validity. No-one wants to have to reach back and re-wire their brain into new habits of thinking, because such a process can be traumatic. It is far easier to hold onto one's ideas and values, and when challenged, the natural reaction is to defend them emotionally without thinking about their origin [5].

8 The two faces of encapsulation

ENCAPSULATION has also been used to discredit traditional architectural styles and throw them out of favor. The meme here is a negative association, which spreads independently of whether the accusation is true or not. This happened to the Beaux-Arts style, which was tainted by association with pre-World-War-I society in supposedly 'decadent' western Europe. The same is true of the Victorian and Edwardian styles in England [25]. The Classical style, after surviving for more than two millennia, was discredited because neoclassical buildings were erected during the Second World War in Germany, Italy, and in Stalinist Russia [25]. The absurdity of this argument does not however undo the remarkably effective use of ENCAPSULATION to further the agenda of modernist architects. As a result, there exists a violent resentment today against traditional styles; although no-one who feels that way can explain logically why that should be so.

Destructive ENCAPSULATION is well known in the political arena, where it is used for character assassination. In the world of art, the Iconoclastic movement declared figural representation to be unholy, despite the complete absence of any such restriction within Christianity. This happened around the 9th century, and led to the wanton destruction of religious paintings and mosaics before it was reversed. Early Christian icons dating to before the 11th century are as a consequence extremely hard to find. A brief resurgence of Iconoclasm occurred in Italy in the 15th century, instigated by the deranged monk Savonarola, which prompted the burning of several of Botticelli's paintings. History is unfortunately replete with examples in which individuals, groups of people, races, ideas, or artifacts are eliminated, after being branded by association within a destructive ENCAPSULATION.

One of the twentieth century's most successful memes is: "*Ornament is a crime*", coined by the Austrian architect Adolf Loos in 1908 [10]. This phrase is impossible to forget; it goes straight to one's memory whether one agrees with its message or not, thus ranking it with the most successful advertising jingles ever. Because of the NOVELTY criterion, the more outrageous social memes are often the most virulent [5]. This particular ENCAPSULATION identifies anyone who dares to enjoy architectural ornament with persons who by creating ornament supposedly become criminals, and "*inflict serious injury on people's health, on the national budget and hence on cultural evolution*" [10]. Infection by this meme continues to this day, since Loos is presented as a pioneer of the modernist movement, and his overly plain buildings (though built with the most expensive materials) feature in histories of European architecture. Something occurring outside established architecture may eventually prove far more damaging in the long term. For millennia, people have built modest structures such as pieces of wall, a raised flower bed, a veranda, or an addition to someone's house, etc. This vast "architecture without architects" is simple, functional, often ornamented, and made out of available materials. Some of mankind's most endearing artifacts are produced within this tradition. They possess an emotional appeal and mathematical coherence that is lost when such structures are replaced by rigid industrial objects trying to emulate a crystalline geometry. People infected with modernist memes are eager to erase their heritage, since it reminds them of the past. Because of inner fear and feelings of inadequacy, people are terrified to risk losing what they believe to be modernist progress. In many societies, it has actually become illegal to build anything that doesn't 'look'

modernist. Something wonderful and complex — a tradition of building small things to please one's emotions — is becoming extinct as a result of a memetic infection.

9 A complexity threshold

The rapid spread of modernism is reminiscent of the spread of biological and computer viruses. What links them is their reduced complexity overhead (i.e., the minimum structural complexity they have to maintain during transfer from site to site). By sacrificing the structural complexity needed for metabolism, viruses gain an unbeatable advantage over more complex, metabolizing life-forms that they infect [20]. There is a parallel here with modernist design as it competed with more complex architectural styles such as Art Nouveau and the Classical style. Any style that attempts to adapt itself to human physical and emotional satisfaction, as well as to local materials and climate, will necessarily exceed a certain complexity threshold. In neglecting those needs — indeed, in making it its explicit aim to ignore them — modernist architecture crossed the complexity threshold going downwards. This brought it an unprecedented advantage, but removed an essential quality that we associate with 'life'.

Although 'life' has not been rigorously defined as a concept, biological life consists of two components: metabolism, and replication [15; 21]. The apparatus for metabolism represents much of what we observe as biological structure in every organism. The machinery for replication, on the other hand, occupies only a limited portion of an organism's structure. A virus replicates its encoded genetic information without being able to metabolize. It is the simplest possible life form, and by this definition, it is not 'alive' in the sense that a more complex metabolizing organism is. In an analogous manner, modernist structures, though immensely successful at replicating in the built environment, do not possess the same degree of 'life' (measured in terms of organized complexity) as do more traditional architectural styles that adapt to human use and emotional needs.

There is a debate going on in evolutionary biology as to whether viruses developed before, concurrently, or after metabolizing life forms [20; 21]. The third option argues that parasitic replicators have to have a population of more complex organisms to parasitize before evolving. A probable scenario for this third option is that some incomplete pieces from the replicating apparatus of an organism found it possible to lead an independent existence outside the metabolizing structure. Whatever the actual case, this third option is intriguing for its parallel to modernist architecture. With the above analogy, modernism could not have taken root before society became complex enough to support it. The intuitive perception of modernist buildings as 'alien' forms invading our cities (and minds) makes more sense in a society that is so morally and ideologically confused as to be in no position to stop the invader.

Evolution relies strongly on the organization of complexity. The metabolizing structure of all life forms exceeds a certain complexity threshold. Natural selection pushes many organisms to become more complex. It is true that some species reach a plateau when their structural complexity provides a reasonably good chance for survival and reproduction. Those that do this have no need to change as long as their environment or ecological niche remain stable. Nevertheless, the direction of evolution as defined by the progress from elementary life forms to humans is one of increasing complexity. A sudden *decrease* in organized complexity thus

appears as a catastrophic reversal akin to species extinction. Just as when viruses kill off a population of mammals, or when computer viruses erase a host of hard disks full of organized data, so the organized complexity of the built environment is decreased when Nineteenth-century buildings are replaced by modernist ones.

The low information content of minimalist design distinguishes it from other, more traditional styles of architecture, as well as from more recent stylistic trends. We want to clarify a misunderstanding in discussions of complexity in architecture. Biological forms are characterized by their extraordinary high degree of organized complexity. A high degree of organized complexity (visual as well as structural) is also found in the great buildings of the past such as mediaeval cathedrals and mosques, and in vernacular architectures. This property should be contrasted with a high degree of *disorganized* complexity that is seen in detailed, busy, but disorganized buildings such as postmodernist and deconstructivist structures. Disorganized complexity is also encoded in the visual cacophony of signs and materials in the suburban commercial strip, and the jumble of neon signs of the Las Vegas casinos. Our age appears incapable of organizing spontaneously-generated complexity, and we believe modernist memes contribute to this deficiency.

10 How architecture perpetuates modernist memes

By a remarkable confluence of historical events and circumstances, selection on the basis of images of emptiness has succeeded in displacing a variety of architectural traditions based on adaptation to human needs. Those who promote modernist structures agree that the style's lower organizational complexity is meant to deliberately contrast with the higher complexity of traditional architecture. Is it possible now to re-establish traditional adaptive design methods in practice? We don't believe that significant changes can come from within mainstream architecture, because it is itself a product of (and is totally dependent upon) modernist memes. Additional insight comes from seeing how three more criteria proposed by Heylighen: AUTHORITY, PUBLICITY, and CONFORMITY, contribute to the propagation and eventual institutionalization of memes [17; 18].

AUTHORITY from famous architects and their sponsors legitimizes design memes in people's minds. The backing from a recognized expert or institution boosts the acceptance of a particular idea [18]. After the Second World War, the United Nations built its headquarters in New York City as a validation of the modernist style. Several progressive governments reinforced this example by building new capital cities in a modernist style: India (Chandigarh); Brazil (Brasilia); Bangladesh (Dacca); and Australia (the post-war buildings in Canberra). The U.S. Government adopted modernism for its international trade missions and exposition spaces, projecting images of prosperity from a superpower, while corporations competed to outdo each other in occupying modernist headquarters. In our times, the administrative buildings of the European Community in Brussels embody modernist memes. (People conveniently forgot that modernism was the official architecture of Fascist Italy).

Setting up a cycle of positive feedback, acceptance of modernist memes by governments and organizations elevated their architects to a position of AUTHORITY. The 1932 exhibition on Modernist Architecture at the Museum of Modern Art in New York was a highly influential

event, using the museum's AUTHORITY to promote the so-called 'International Style'. (After New York, the exhibition travelled for seven years around the United States [9]). Two former directors of the German Bauhaus school were subsequently made heads of Architecture schools in the United States when they emigrated from Europe. Those architects then used their positions to promote modernist memes through their teaching, and by praising each other in the media. Their positions of AUTHORITY also guaranteed them more commissions to erect modernist buildings. The public rarely feels confident enough to challenge the AUTHORITY of individuals presented as the world's experts on the topic, even if what they say runs contrary to people's basic feelings and intuitions.

Professors at prestigious universities such as Sigfried Giedion and Nikolaus Pevsner — the first enormously influential as the Secretary of *CIAM (Congrès International d'Architecture Moderne)* — wrote scholarly "histories" of architecture that twisted facts to promote an ideology [25]. Modernism was falsely presented as the inevitable end result of the continuous evolution of historical architectures, instead of the radical negation of traditional styles that it represents. By claiming that modernism is not a style, and thus not subject to stylistic competition, they implied for it an AUTHORITY above and beyond architecture. Styles that modernism competed with and displaced (e.g., Neoclassical; Edwardian) were either dismissed as irrelevant, morally reprehensible, and were ignored altogether, or they were misleadingly appropriated as ancestors of modernism (e.g., Art Nouveau; Expressionism). An invented architectural history thus endowed modernism with false historical and moral AUTHORITY. Those treatises, along with others bearing the same misleading message, became the standard textbooks for more than one generation of architecture students.

An essential feature of evolution is that complex systems build upon existing complex systems: each new development adds something to what already works. New layers of functionality develop on top of older structures, without altering them radically. This summarizes both the advantages and disadvantages of cumulative design by selection [14]. We can trace evolutionary ancestry by looking for features in common with less developed organisms on the evolutionary scale; some of which survive in an inactive or useless form. For an architectural example, the Classical style retains features of its ancestral wooden construction, although they make no structural sense when building with stone. Nineteenth-century styles retained much of what had developed up until then. As modernist architecture was intent on destroying and replacing all past and existing styles, however, it cannot be termed an evolution of those styles.

PUBLICITY is the effort to spread an idea; often an ideology includes explicit injunctions that believers should engage in propaganda [18]. In architecture that is taken care of by a wealth of picture-filled books and architectural magazines, films, television documentaries, and the press; all of which promote modernist memes. These offer a platform from which often confused ideas are endowed with visual legitimacy. The 1932 'International Style' exhibition was conceived as a publicity campaign for modernist architecture, and its catalogue as a propaganda tool for disseminating the new style in the United States [9]. Modernist architectural memes spread through advertising techniques coupled with proselytizing in architecture schools. Since its inception in 1979, the Pritzker architecture prize has been awarded to architects who best embody the latest trend in design; such prestige and accompanying PUBLICITY in turn helps to perpetuate those fashion trends. The same is true for numerous other architectural prizes of lesser

prestige. Those prize-winning built examples are publicized by the media, and influence the design of new buildings.

CONFORMITY guarantees that newcomers into a group will be infected by an accepted meme, even though it rejects sound knowledge and contradicts established beliefs [17]. CONFORMITY pressure establishes and maintains an invariant belief over a group of people [17; 18]. Peer pressure from the architectural community maintains approved architectural images, with the threat of ostracism for apostates [25]. Many cases are known of ridicule heaped upon architects who stray from the official design style. Architectural magazines tend to publish only articles featuring buildings that maintain the *status quo*. Architecture students are infected with modernist memes by their teachers, and are under pressure to conform to the accepted style. The teaching of architecture has changed since most architecture schools adopted the Bauhaus concepts, so that today design is almost entirely image-driven. It is very difficult even to discuss adaptive design such as Alexandrine patterns [1; 24]. Academic architects still invoke the tired 'modern versus traditional' argument, which ultimately thwarts creative endeavor.

11 Modernism has become an institution

This paper described how modernist memes spread in society, to the point where they displaced most other architectural styles. We now wish to discuss the opposite process: how to remove modernist memes from our society. A group of memes achieves ultimate success by becoming institutionalized. The rigidity of institutionalized memes then makes it extremely tough to get rid of them. This section explains the great difficulty in displacing modernist memes from today's architectural establishment. Nevertheless, we are optimistic that people (most likely users rather than architects) will begin to consider alternatives once they see the connection between modernism and memetic infection.

An institutional system will take actions to protect its political base, which results in a conceptual bias. Decisions are made as to which information is relevant to it (i.e., relevant to architecture as defined by those in power), whereas other conceptual models will be ignored. The political agenda favors specific issues, deciding as well how dialogue with competing issues is to be addressed, if at all [13]. The same rules apply to any other meme group that has become institutionalized, and are not specific to either architecture, or design [13]. The institution defines both the importance and the interpretation of concepts, so that it controls whether a particular idea will be discussed, and whether any action will be taken. Not surprisingly, arguments and actions that do not fit into the conceptual framework of those in power are not going to be pursued.

This analysis is confirmed by how architecture has progressed since adopting modernism. The institutionalization of modernism in our society acts as a filter for innovation within architectural design. Despite well-publicized reactions against the empty forms of early modernism, most of the original visual memes have been retained in post-modern design. The overall forms may vary, yet the basic 'look' is still familiar. Architecture today remains at its core non-adaptive to human needs; that basic aspect certainly has not changed. Neither has the proscription against detailed ornamentation and color that the early modernists imposed. Materials tend, on the

whole, to be those preferred by the early modernists because of their universality, and even when traditional materials are used, they are used in ways so as to mimic "pure" modernist surfaces. Because every institutional structure acts as a memetic filter, innovative concepts may be able to evolve only outside it. In the case of architecture, the evolution of design that is adaptive to human needs is taking place mostly outside the establishment: either spurred by architects who have been evicted from the establishment, or by other professionals who have discovered that the existing complex is too rigid to deal with societal problems. The establishment is reacting in a predictable manner by ignoring innovations. Instead, it underlines its absolute control by allowing limited debate within certain boundaries. The debate is very tightly controlled, however, and is never allowed to endanger the institutional basis. Thus, the declaration of the postmodernists that 'modernism is dead' should be interpreted for what it really is: a smoke-screen meant to protect the architectural establishment from any serious attack.

The proponents of modernist design sought to eliminate competing styles by employing two tactics: aggressive attack, and ridicule. The switch from one to the other marks the point when modernism became an institution. In the years up to the 1950s when modernism was peripheral and was trying to gain the upper hand, destructive encapsulation was used with great effect. By the time this tactic succeeded, the modernist establishment found it more appropriate to express its strength by ridiculing its competition. The word 'pastiche' was henceforth used to make fun of any architects who tried to incorporate traditional elements into their designs. 'Pastiche' is the artistic equivalent of 'plagiarism' in the sciences, and implies that such an architect is not being original. In fact, those who follow the establishment typology are doing exactly the same thing. Developments in architectural design touch upon the commercial benefits of the modernist style in comparison to other factors. Modernist designs, because of their simplicity and context independence, are designs that can be produced industrially for a reasonable price. The institutionalization of modernist architecture has taken place in the entire construction industry, driven by the rise of industrial construction. This institution is separate, and more powerful than architectural education, institutes, and magazines. Some authors have identified this as the dominant factor for modernism's success [2]. In accepting a Faustian bargain, architects provided ever plainer designs that could be built more cheaply, until by now the threshold is so low that it is extremely difficult to raise. Any change that threatens to increase construction costs while lowering productivity in the construction industry is going to be fought by a massive establishment.

12 Conclusion

The idea of design as a Darwinian process that relies on selection has interesting ramifications for architecture as a whole. This explanation of how design emerges in the human mind reveals a split between design methods based on stereotyped images, and those based on adaptation to human needs. Both architectural and popular literatures come back to the theme that a majority of twentieth-century buildings provide neither the physical nor the emotional comfort for their users that older buildings — which are built in a freer, more adaptive style — almost invariably do. Nevertheless, despite such strong criticisms, certain visual styles continue to dominate construction and design practice today. An answer to why this is so comes from visual memes: self-sustaining conceptual entities that become encapsulated in human memory. Originally introduced in discussions of evolutionary biology, memes serve well to explain why architectural

fashions survive and propagate. In particular, memes explain why the modernist style has achieved such remarkable success in displacing traditional architectural styles.

GERMS AND IDEAS

By
André Siegfried

The spreading of germs and ideas

There is a striking parallel between the spreading of germs and the spreading of ideas or propaganda. On the one hand we are dealing with a virus which can be transported and transmitted under certain conditions which favor or limit its transportation or transmission: on the other hand with ideas, religions, and doctrines, which can be described as germs, benevolent or malevolent, according to the point of view one takes up. These germs can either remain at their source and be sterile, or emerge in the spreading of infection. The vocabulary which normally comes to mind is that of medicine. Conditions of infection, besides, will also be the same as in the domain of health. For diffusion to take place we must necessarily have a germ, a carrier, and receptive surroundings. It is then, as in the case of epidemics, a matter of contacts, made easier by the techniques of communication or delayed by obstacles arising from custom or from administration. Sociology and biology are curiously akin in this.

Conditions necessary for the initial germ to spread

The initial germ cannot travel on its own; it needs a carrier, which may be a man, a journal, a book, a pamphlet, not to mention the radio or the cinema or the television screen.

The human being is in the circumstances the most natural transmitting agent. A particular man, on moving from one place to another, will take with him a doctrine, a religion, a germ of opposition or revolt. It may be that he feels conviction about it, like a missionary, an apostle, or a propagandist, but it might also be the case that such an agent remains unconscious of the contagion he spreads, carrying a germ of which he does not suspect either the harmfulness or even the existence: just as there are carriers of non-apparent infections, who know nothing of the virus they harbor, which is undiscovered even by doctors. These are the most dangerous. The carrier who is admitted to be such will preach, harangue, teach, discuss, insinuate, openly sowing the seed along his path, which means that he can be stopped or refuted; but with the unconscious or camouflaged carrier diffusion will be infinitely more insidious: it may be an army soldier in a distant garrison or in the battle-field, a peddler on his rounds, a laborer recruited for some distant scheme, or even the valet of some millionaire touring round the world. The fantasy, the unpredictability of human contacts is without limit, surpassing the scope of even the wildest imagination. We have only to consider the pollen spread to the uttermost ends of the ancient world by those bees, the Tartar conquerors; the fecundation which those kill-joys, the nomads, periodically brought to the owners of solid hereditary estates; the incessant temptations of neighboring idolatries for the faithful of the true God; or the unforeseen spiritual transports brought about by the Parthians, the Mongols, and the Arabs. The world is infinitely more permeable than one could believe, and in order to be so it has not had to wait for the telephone, the telegraph or the aeroplane to conquer distance and time for us.

We have said that infection may take place through the reading or the hearing of something from a distant source, or through the sight of some image, but, all the same, human intervention will have been necessary: the germ may be laid in a book, in a screen production, or in a purely formal rite, yet a human intermediary will have been necessary; the source remains inevitably human, for one cannot imagine an idea without a human reservoir, comparable to the germ reservoir in the preservation and transmission of diseases. As far as the virus reservoirs in animals are concerned, however, the comparison stops short, for one can hardly imagine the monkey or the rat playing the part in mind communication that they play in the case of the yellow fever or the plague, even though they be the library rats of the Fable.

Routes followed in the diffusion of ideas

Here we again find the routes which we have already come across in the spreading of germs, which are naturally a subdivision of the large class of world communications in general. Thus we have to remember the caravans, those ancient instruments of trade, pedlary, pilgrimages, sea itineraries, immigration routes, and missionary routes, which are often indistinguishable from routes of conquest - a list that goes back over the ages. If we are dealing with modern routes, conditions of contact remain the same, but transport techniques have supplied the railway, the motorway, and the airway. The nature of communications does not alter, but their intensity increases, the route becoming the instrument *par excellence* of penetration, now as strong as a battering ram able to knock down any obstacle, now supple., subtle, and capable of insinuating itself everywhere: the work of Gothard, by introducing a foreign labor force into a swiss canton which was still living in the Middle Ages, changed the political and social balance. In his novel *Les hommes de la route*, André Chamson has described a similar revolution brought to the Cévennes in an offensive on the part of the Highways Department. In building roads, in laying down railways, in setting up strings of naval bases across the seas, and in forming a network of substructures for the needs of air travel, pioneers bring with them not only their techniques but also their ideas, and then, after them, other men use these paths to convey products of all kinds, including those of the mind. The part that chance then plays in these contacts surpasses the imagination and one must have recourse to the demoniac fantasy of the association of ideas to find any image for it. The insinuation of idea germs can come about through the arrival of tourists, through a detachment of foreign workers, through an army of occupation, through the enrollment of foreign students at a university, through then introduction to non-immunized surroundings of a single individual, or sometimes of a journal or a book, or through the unexpected conjunction of something read with a state of mind which happens to be receptive at that particular moment. My grandfather, who was a notary in the chief town of one of the districts of Ardèche, while sailing along the Rhône towards Lyons to see a performance of *Rachel*, was engaged during the journey in reading a Bible that a friend had put into his hands --- it was during the time of the Revival; he did not see *Rachel*, came back to his town, and after conversion, became a minister. the example is typical of many. Infections, epidemics, are born in this way. "There are forms of madness which can be caught in the same way as infectious diseases," says the moralist. The types of human carrier are innumerable - each of us being one, on occasion - but certain categories of men are so by profession, or even simply by temperament: As examples we can quote the missionary, the traditional peddler, the political agitator, the leader feared by his employer, the canvasser in an election, the publicity agent, and the American [travelling] salesman: from the sociological point of view the possibly endless list would be most

interesting to draw up. In any case, the "evil spirit" introduced by the purest chance into given surroundings, is sure to breed trouble and disorder, and one can easily understand the employer, whoever he may be, shielding himself from it *as from the plague*.

Environmental conditions

The environment, however, must be suitable. For diffusion to take place the environment must necessarily be receptive, that is, suitable for the development of the germ, without which conditions it will remain sterile, or else there may only be a localized and temporary infection. It may also happen that the human carrier disappears of his own accord, or is simply suppressed as being harmful: this radical suppression has the same result as it has on infections. In the geographical studies of public opinion that I made on the borders of the Central Plateau in contact with the Mediterranean world, I found many examples of similar infection reaching upwards and then stopping and becoming sterile. Extreme leftist ideas thrive and multiply on the coast in the form of radicalism, socialism, or communism, according to the times, and they have a tendency to travel up towards the mountains along the valleys, just as Mediterranean qualities work their way up towards the plateau along the routes most exposed to the sun. Thus between Hérault and Aveyron, socialist propaganda between the two wars raised a small extremist center at Séverac-le-Château in Aveyron, among the railway workers; but the atmosphere was evidently not propitious, for its virulence remained limited and localized. If extremism thrives in low-lying country, altitude is not favorable to it. Before 1914, as I remember, I observed an analogous transmission of germs in Hérault, Gard and Lozère, with no consequences. In the distant time of the Dreyfus Affair, when a new generation in forward-looking circles was substituting the socialism of Jaurès and de Guesde for the old radicalism of Clemenceau and Pelletan, there were students in the Faculty of Medicine of Montpellier University who were responding with enthusiasm to this propaganda. One of them, called Phalippoux (I still remember his name) going along the valleys of the Basses Cévennes, had carried the revolutionary good word, which was then Jaurèsism, as far as the parishes of the district of Florac, where the protest element declared itself left-wing in virtue of a tradition of resistance stemming from the Desert and persecution. Many of the good Huguenot electors of the time voted therefore "to the left" and "always to the left" --- as a young greenhorn who had only just attained his majority said to me: "I am a Marxist, and I vote on principle for the most advanced side." The agitator from Montpellier had thus created small revolutionary centers at Pont-de-Monvert and Barre-des-Cévennes. But the altitude, physical as well as moral, no doubt was unfavorable, and the movement never developed; it is yet another example of infection setting up a small center and then dying a natural death. We could quote numberless examples, in the sphere of religion as of politics: the rare and sporadic Christian conquests in Asia suffer from these limitations: they form small centers, active and not without vitality, but discontinuous and unable to spread, and becoming endemic only through a kind of adaptation to their surroundings, as is the case with Portuguese Catholicism on the Malabar Coast. Sometimes all that is needed is that the merest chance, or else the founding of a new transport route, should carry far afield some bearer of religious conviction: this is how some negro employees travelling in the Southern Pacific Pullman between New Orleans and Los Angeles, once brought to South California the germ of some sect or other which held that Jesus and the Apostles were black; one can imagine that the infection would not spread very far beyond the railroad.

Defense measures and their degree of efficacy

In order to destroy and sterilize a germ, or simply to circumscribe its diffusion, one can, as in the struggle against disease, proceed in different ways.

The most decisive action is to destroy the germ at its source. But this is often difficult. Either one does not know the germ or, if one knows it, one does not know exactly where to find it. It may be that its possibilities of diffusion have not been properly estimated. It may also be that the germ has multiplied in such a fashion that one is defenseless, tempted to say with the combatant who is completely surrounded: "They are too many!" We can well understand the reaction of Simon de Montfort at Béziers in his extermination of the Cathars: "Kill them all, God will recognize his own!" The Albigensian germ was in fact completely destroyed, and since then it has only existed in the memory.

Another defense, which is the most usual, consists in suppressing the carrier, or at least in preventing him from penetrating the territory that one wishes to preserve. Thus all the agents of diffusion of this or that doctrine will be systematically destroyed. At all events their entry will be prevented by an impassable barrier at the frontier. That is the traditional Russian system, favored by the Czars long before it was used, as today, by the Soviets. It is also the American system of the immigration quota, which tends to limit the entry of immigrants of Latin or Slav origin, whose influence, it is assumed, might compromise the orthodox Anglo-Saxon tradition. After the First World War America thought that she could in this way keep out a European infection that she considered insidiously Communistic. McCarthyism, after the Second World War, was but a temporary paroxysm of this defensive obsession. If however the infecting agent somehow succeeds in getting in (and how can one really prevent this?) every effort will be made to watch him, to limit his activities and to render him harmless. There may be some doubt as to his degree of harmfulness, and, in this case, he will be subjected to some sort of quarantine. I have been assured that, in the Province of Quebec, the orthodoxy of whose Catholicism is well known, a Canadian student returning from any French university is placed under observation for a certain period, to make sure that no infectious disease develops in him.

The procedure which is most prudent is naturally to take preventive measures: censorship of the press or of books, examination of luggage to make sure that it contains no subversive publication, police supervision of suspects, religious persecution, to say nothing of these so-called "psychological" operations of re-education, de-fanaticizing and re-adaptation which are the shame of our century. The Russians and the Chinese are past masters at this type of treatment, but it certainly seems to have been used occasionally in the American army during the Korean war, and it would be most reassuring to know that it is not practiced in North Africa. Hitler caused this technique to progress in a truly horrifying way and since then the demoniac progress of neuro-surgery has placed in the hands of experimenters in the matter instruments capable of working miracles in the domain of evil.

One wonders, however, how far such procedures are effective against that winged germ, often invisible, which is the mind. If one "kills them all," as in the case of Albigensian Manicheism, the enterprise is successful, but if as much as one remains propagation starts again, as is the case with the majority of persecutions: whether it is a case of the Protestants after the revocation of

the Edict of Nantes, or the Jews throughout the ages, or of the Armenians assassinated *en masse* by the Turks, the operation has proved itself useless, for there are still Protestants, Jews and Armenians. The sterilization of the surroundings by the suppression of all contact with the exterior has produced the expected effect in Russia: the state succeeds in preventing the Soviet citizen from knowing what is going on outside, and besides, if any outside propaganda evoked the slightest response this would soon be suppressed by a police force which could, in this context, be described as "sanitary." The iron curtain and the bamboo curtain are, from this point of view, as effective a protection as the ancient wall of China, which protected the refined civilization of the Yangtze Kiang against the raids of the Tartar hordes.

So far the comparison between the epidemics of the body and those of the mind has proved fruitful. It remains so as long as the question is one of immunization or vaccination. The laws of nature have given the organism a mechanism for self-defense, corresponding to a fundamental instinct for restoring the balance. That is the significance of immunity, of which vaccination is but a derivative. In the defense measures that human societies adopt against the attacks of propaganda or the penetration of new ideas, immunization and vaccination likewise exist. The virulence of a given doctrine is attenuated by its adapting itself to its surroundings or simply through habit. It can even happen that the injection of a reduced dose can bring with it immunization against a more active form. I seem to have observed several times in Latin America, especially in Argentina, that a particular form of demagogy is the equivalent of a social vaccine against communism. The same thing can be observed in the United States with respect to Irish demagogy, which never goes as far as revolution. A given reform, subtly inspired by the menace itself, will often prevent the disease from declaring itself or at least from spreading when a local infection appears. A healthy society has its own defenses against the infections which might endanger the integrity of its personality. On the other hand an unhealthy society will catch all the illnesses that are going, and will react to all the infections. Rome, in its decline, was not able to defend itself against Christianity. Bismarck said of Russia that she had no business in Europe, and would just catch all its diseases. Freudian psychology spread easily over the Protestant countries, particularly the United States and Switzerland, while Catholic countries put up an effective resistance.

Certain doctrines and certain religions spread like epidemics, following the same lines of least resistance, coming up against the same obstacles, first striking out - depending on the transport available - towards the main centers of communication and distribution, from which they then spread in all directions. Conditions are the same as those we analyzed above with regard to the great pandemics of the nineteenth century, halting places and ports of call being the first to be affected, remote places only being reached after some delay. This explains why certain isolated districts hidden in the mountains or forests escape infection for so long, acting as strongholds of resistance to the infection of progress, and as the last refuge of conservatism.

A typical example of a spiritual epidemic is to be found in the spread of Christianity over the ancient world, which was exceptionally permeable from a spiritual point of view in Roman times. What do we find if we describe this in biological terms? The initial germ is at Jerusalem, but it might have given rise to a merely local infection, limited to the Jewish society in which Christ carried out his apostleship: the apostles, good Jews, who no doubt meant to remain within their own religion, would probably not have spread their faith to any great distance. But there

were proselytes among the first Christians, Hellenized Jews or Judaized Greeks, and in their ranks was Stephen, the first martyr. After he had been stoned to death by the fanatics of orthodoxy, his closest disciples, fleeing from Jerusalem, thus fled from the capital to the coasts of Asia Minor, where Jews and Greeks met in the synagogues. Here they were in surroundings which lent themselves admirably to the diffusion of the doctrine which Jerusalem refused to accept, and so, by degrees, Christian centers were constituted in Antioch, Tarsus, Ephesus, Thessalonika and Corinth. The carriers, in this instance, were the disciples of Stephen, the converted Judaeo-Greeks, the missionary apostles in whose front rank we find Saint Paul, the carrier *par excellence* through his immense missionary activity. Where the atmosphere was favorable, churches sprang up; where it was not, the Christian seed remained sterile: this was the case at Athens, where the Apostle preached as if in the wilderness. But in other places it was successful, and in the Mediterranean where everything tended towards Rome, it was inevitable that sooner or later the capital of the world should be affected. From Rome the diffusion became generalized and, everything considered, took on for the people of the time, the nature and extent of a pandemic.

The itineraries of Saint Paul are, from this point of view, singularly revealing. The apostle chose the big towns placed along the most frequented lines of communication, because there he found the people less fixed and established, and so more accessible to his preaching; and also because, no doubt, as a tentmaker he found better possibilities there of earning his living. The pattern of roads, the network of sailing routes, obviously also counted for something, for there is a curious mixture of settled plans and irrational impulses in the missionary method. It was natural that he should finally end up in Rome, and, had he not perished under Nero's persecution, doubtless he would have gone on as far as Spain and Gaul. The pressure of East upon West which, in the second and third centuries reached its maximum intensity, meant that all theological developments taking place in Western Asia had an immediate or almost immediate repercussion in Rome, where there were important Asiatic colonies. Maurice Goguel, the great historian of early Christianity, to whom I am indebted for these thoughts on the geography of religion, believed that an exciting study could be made of the geography of primitive Christianity and the manner in which early Catholicism was built up by a sort of concentration, fusing types of Christianity which at first had differed considerably. The first Christians traveled about a great deal, and their journeys and highly developed practice of hospitality did much to unify them. Christianity thus moved westwards, the center of gravity moving from Jerusalem to Antioch, then to Ephesus, and finally to Rome after a fruitless attempt on the part of Corinth to compete with the capital.

Another example of the geographical extension of a religion can be found at more or less the same time in the spread of the mysteries of Mithras, as appears from the classical research of Franz Cumont. The main Mithraic monuments have been found on the frontiers of the Empire, strung out along, and protected by the *Limes*. It is clear that the Roman legions were the means of transmission here; it is a case, and a very curious one, of an occupational infection.

We have made use of the same vocabulary to speak of the spread of diseases and of ideas and propaganda: virus, germ, source; carrier, soil, surroundings; contact, contagion, infection, contamination, endemic, epidemic, pandemic; prevention, inoculation, sterilization, immunization, vaccination, quarantine. Surely we have more than a superficial coincidence here:

both in the domain of biology and in the world of ideas, certain reactions are shown which are common to all living beings.

MEMECOSYSTEMS: ARE ANIMAL MINDS SUITABLE HABITATS FOR MEMES?

By

Brent Silby

Department of Philosophy
University of Canterbury
New Zealand

Abstract

Milk-bottle opening behavior in a species of bird known as the British tit has been put forward as an example of a meme in a non-human animal. The existence of this type of case has led some thinkers to believe that non-human minds can acquire memes. I believe that the British tit's behavior has been misinterpreted as memetic. In this ePaper, I argue that milk-bottle opening in the British tit can be explained by appealing to its innate behavioral repertoire. I then suggest that the question of memes in animal minds should be considered on a case by case basis.

1. Introduction

In their paper "Do Animals Have Memes?" (1999) Simon Reader and Kevin Laland suggest that animal minds are suitable habitats for memes. Their ideas come about after a critical examination of points that Susan Blackmore raises in her book *The Meme Machine* (1999). Blackmore argues that humans are the only animals with minds capable of supporting memes. Reader and Laland disagree and attempt to find some examples of memetic transfer in non-human animals.

In this ePaper, I will examine Reader and Laland's claims. I will focus mainly on their suggestion that the British tit's milk-bottle opening behavior is a meme. My objective will be to show that Reader and Laland's claim is wrong, and that the British tit's behavior is not a meme. I will start by outlining Reader and Laland's argument and will show that their claims rely on an incomplete definition of what a meme is. I will then offer a firm definition for the meme, after which I will provide an alternative explanation for the milk-bottle opening behavior exhibited by the British tit. My next point will be that the question of memes in animals should be answered on a case by case basis. My conclusion will be that examples such as milk-bottle opening in the British tit do not provide evidence of memes in animals.

2. Memes in the Minds of Animals

According to Susan Blackmore (1999), imitation is the primary mechanism by which a meme replicates and finds its way into a new mind. If she is right, it would seem that memes are exclusive to animals that have the capacity to imitate behavior. So far this ability seems to be found only in humans and some species of birds, members of which can mimic certain sounds and calls.

Reader and Laland agree that there is limited evidence of imitation in non-human animals, but argue that imitation should not be the defining feature of a meme (Reader & Laland 1999). They suggest that limiting memetic transfer to acts of imitation is restrictive and cuts out a significant range of behavioral transmission. For Reader and Laland, the psychological process underlying the transmission of information is not a determining feature of memetic replication. Instead, they argue that *transmission fidelity* is the key feature of memetic replication. This is to say that regardless of the means by which a behavior is replicated, a memetic transfer can be said to have taken place if the resulting behavior is a *high quality copy* of the original behavior. Reader and Laland are right to make this point. If acts of imitation were the only way that memes could spread, then it would seem senseless to speak of memes entering human minds from written material or from musical notation. In these cases information that produces behavior is transferred with no observation of the original behavior -- it is not mimicked. Music can, of course, be imitated, but most of the time musical memes are encoded in a musical score and are assimilated to new minds when the score is read.

To support their claims, Reader and Laland point to evidence of behavioral transmission in non-humans animals that does not come about through imitation. The examples used are cases of *social learning* -- learning that occurs when behavior is *influenced* by observation of other animals (Reader & Laland 1999). Perhaps the most significant example for Reader and Laland is milk-bottle opening in British birds. In some areas of Britain, a species of bird known as the British tit has acquired the behavior of opening milk bottles to get cream. The tit finds milk bottles at house doors and pecks away at the foil bottle top in order to get access to the cream that sits on top of the milk. When other tits observe this behavior, they try it out themselves and soon learn that if they open milk bottles, they are rewarded. It is important to note that the tits are not *imitating* each other. They are simply being attracted to objects that other tits are pecking at. According to Reader and Laland, the spread of this behavior throughout the tit population in Britain shows that memetic transfer has taken place. Opening milk bottles is not innate to the tit - it is learned -- and the behavior replicates with high fidelity showing that it is a meme. Since the British tit can have memes, Reader and Laland conclude that animals have memes.

3. Is this stretching the Meme too far?

To effectively assess Reader and Laland's claims we need to know exactly what a meme is. Without a firm definition, it is possible for theorists to make any claims about memetic transmission. Reader and Laland want to relax the criteria that past thinkers have placed on the meme, but I think they are relaxing the criteria too far. If we travel down the road that Reader and Laland are opening up, we will end up describing all conditioned behavior as memetic. On the surface, this might seem acceptable, but it is only acceptable if we have a very loose definition of a meme.

Why is such a loose definition unacceptable? The reason is that it makes the term 'meme' redundant. The best way to understand this is to consider the parallel situation in genetics. A gene is a packet of instructions encoded in DNA, which directs the development of cells. Now, if someone comes along and claims that all chemical processes are genetic, then the term gene would apply to everything that goes on in the body. Not only would we describe an animal's physical and mental characteristics as genetic, we would also describe the chemical process

underlying digestion as genetic. But this is not what genetics is about. Genetics attempts to explain things at a higher level than common chemical process. The same is true of memetics. Memes are used to describe high level behavior that is not an innate part of an organism's behavioral repertoire.

In this section, I will offer a firm definition of the meme and will use this definition to show why the spread of milk-bottle opening in British birds is not memetic.

3.1 What is a Meme?

Memes are best thought of as sets of instructions that can be followed to produce behavior (see Silby 2000c). Instructions can be encoded in a number of formats, including:

- 1) Musical notation,
- 2) Written text,
- 3) Visible (or vocal) action,
- 4) Connectionist networks such as the neural structure of the brain.

A set of instructions that produces the behavior of, say, whistling the first 4 notes of Beethoven's fifth symphony (a well used example) can be encoded in any of these mediums. When the instructions are followed, the same behavior will result. When a mind encounters an instruction set that produces behavior (say a musical score), it can reproduce that behavior by creating an appropriate neural "program". To understand this, consider a similar situation in the world of robotics. Imagine that a robot is developed that contains a number of built in programs. These programs provide it with behavior essential for its survival. The robot's behavior might include walking, avoiding obstacles, grasping at objects, and the production of certain vocal sounds. Suppose that engineers also give the robot a program that gives it the ability to write small behavioral routines. In effect, this program gives the robot a means by which it can alter its own behavior by writing new programs. Suppose that a feature of this innate behavioral program is that it allows the robot to *observe* the behavior of other robots and write programs that produces the same behavior. In other words, the robot can *imitate* behavior. Now, the question is: what, exactly, are the programs that the robot writes for itself? They are not a part of the robot's innate behavior and they are produced primarily through imitation. They can be translated into different languages and written down on paper. They can also be transmitted to other robots who read the instructions or who imitate the behavior and write their own programs. These behavioral programs are what we are talking about when we speak of memes.

This is precisely the sort of process that goes on in humans. At some point in our history, biological evolution provided our ancestors with a capacity to imitate behavior. This meant that when humans observed the behavior of others, their brains would create the neural wiring needed to produce the same behavior. Such neural wiring patterns are lists of instructions, which can be translated into other mediums such as written language, outward behavior, or computer code. A list of instructions that produces behavior is the thing that spreads into the minds of others. A list of instructions that produces behavior is a meme.

3.2 Why do British Birds not have a milk-bottle opening meme?

Given the above definition of the meme, it would seem that British tits do not have an 'open milk-bottle' meme. This is because British tits have not acquired any new behavior. Blackmore (1999) suggests that the British tits already knew *how* to peck and it was simply a matter of one tit being attracted to another -- who happened to be sitting on a milk bottle -- and then carrying out its innate pecking behavior. I think it is also possible that a tit would be attracted to a milk bottle even if no other tit happened to be around. Most birds have an innate attraction to bright shiny objects, and milk-bottle-tops are usually made out of a silvery foil. Milk-bottle-tops must stand out like bright beacons for passing birds, who feel compelled to land and carry out their innate pecking behavior. Encountering cream beneath the silver foil would *reinforce* the behavior and make it more likely to occur in the future. However, because no *new* information has entered the bird's mind and no *new* behavior has been produced, milk-bottle opening in birds cannot be counted as a meme.

Reader and Laland believe they have an answer to this objection. Their answer draws a parallel between the British tit's milk-bottle opening behavior and the behavior of a human tennis player. For Reader and Laland, a tennis player acquires tennis playing memes by observing other tennis players. These memes carry information about the appropriate location to play, the objects a player uses, and how the player should move in a certain way to hit the ball. They go on to suggest that the tennis player does not learn any new motor behavior such as running, holding, waving arms, or hitting, because these are already a part of their behavioral repertoire. The tennis player is carrying out innate behavior in order to achieve a non-innate goal. Reader and Laland then state that "*Exactly the same logic applies to milk-bottle-top opening birds*" (Reader & Laland 1999). The tits are not learning how to peck at milk-bottle-tops, just as the tennis player is not learning how to run or swing her arms around. They are, however, learning to peck a *particular* object to get cream, and this is a behavior and goal that is not innately defined. Therefore, milk-bottle opening in the tit is a meme.

The problem with Reader and Laland's suggestion is that they are glossing over important differences between the two cases. It is true that tennis players are carrying out innate movements, and it is true that the British tit is carrying out innate behavior. But the difference is that the tennis player's movements are combined in a non-innate fashion, whereas the tit's behavior is exactly the same as it would be if it was landing and pecking at any object. We would not be surprised if we saw a tit land on an apple and start pecking at it. Nor would we be surprised if the tit started pecking at the ground. So what is so special about a tit pecking at a milk bottle? Pecking is simply something that the British tit does. Also, consider the different reasons behind the tennis player and tit's behavior. The tennis player behaves in a specific way in order to win the game, which is a *socially defined* goal. The goal of the tit is to feed, and regardless of what food it happens to find, feeding is an innate objective.

There are also important differences in how the behavior is learned. The tennis player learns through imitation and verbal instruction, which are methods of passing on information that the tennis player does not already possess. The tit's primary method of learning is through behavioral conditioning. When a desirable outcome occurs (getting the cream), the behavior of pecking milk-bottles is strengthened. But this is not a memetic transfer of information, because no *new*

behavioral information has been assimilated by the tit. No information (or instruction set) is being moved from one mind to another so no memes have been copied. At most, the case of the British tit is an example of innate behavior being *triggered* through observation and *reinforced* through reward.

3.3 Does this mean that animals don't have memes?

The quick answer to this question is, no! All I have shown is that the spread of milk-bottle opening in British birds is not an example of memetic transfer in animals. There may be a number of animal minds that can support memes, but I think caution is needed before we make any definite claims. Because of the diverse range of cognitive ability among species on Earth, we should consider the evidence on a case by case basis. The case of milk-bottle opening in the British tit is not a meme, but there are cases of bird behavior that definitely point to the existence of memes. For example, certain species of bird can imitate sounds ranging from the calls of other birds to the sound of a telephone ring. The production of such sounds is not innate to the bird, so we must conclude that some sort of memetic transfer takes place. Something in the bird produces the neural wiring required to enable it to reproduce the sounds it hears in the environment.

One way to check if memes are involved in animal behavior is to see if the behavior is spread through imitation. For example, if a dog (Fred) watches a person (Roger) jump through a hoop and then copies the behavior and jumps through the hoop himself, we could suppose that the *idea* of jumping through the hoop was passed from Roger to Fred. The hoop jumping meme would have copied itself into Fred's mind through the process of observation and imitation. I think it would be unlikely for this to happen. Dogs do not seem to have the capacity to observe and then copy behavior. Getting a dog to jump through a hoop requires a long period of behavioral conditioning. Furthermore, it is possible that coordinated jumping is actually innate to dog behavior, so we might not be correct in suggesting that jumping through a hoop is a meme.

There are some examples of animal behavior that look memetic. Some dogs can be trained to balance and walk on a moving ball. I find it difficult to believe that such behavior is innate, so it might be accurate to consider 'walking on a ball' behavior to be memetic. Of course, a dog cannot learn to balance on a ball by watching another dog. The only way that a dog can learn to walk on a ball is through extensive training and reinforcement. It seems that if walking on a ball is a meme, then it is a meme that has a very limited potential for replication. Since dogs cannot copy each other, the 'walk on a ball' meme can only replicate when the behavior is viewed by a human and then implanted into another dog's mind through a similar process of training.

Other possibilities of memes in animals include the choreographed walking of dressage horses, the transmission of directional information in honey bees, and food washing in Japanese macaques (as mentioned by Reader and Laland). The important point to note is that the *possibility* of memes in these animals is not enough to conclude that there *are* memes in these animals. Each case must be assessed independently. Perhaps the best way to test whether a behavior is innate or memetic is to isolate a member of the species in question. If, for example, a Japanese macaque was isolated from birth we could observe its behavior and find out if it has the compulsion to wash its food. The result of this test would settle the question for the Japanese macaque, but would leave the question of other animals open.

4. What have I shown?

My goal has been to show that milk-bottle opening in the British tit is not a meme. To accomplish this goal, I offered a firm definition of the meme and worked with this definition to show that the spread of milk-bottle opening behavior in the tit does not exhibit the features of memetic transmission. According to the definition I offered, a meme is a collection of instructions that, when followed, give rise to behavior. These instructions can be encoded in a number of mediums including the neural pathways of the brain. The most important feature of memetic transmission is that the instructions transferred are new, and did not already exist in the mind of the receiver. In this way, we can say that the acquisition of a meme gives rise to a new, non-innate behavior. Since the British tit has an innate attraction to other tits, and since pecking at objects is innate to the tit, we must conclude that milk-bottle opening is not the result of new behavior and is therefore not memetic.

I cannot show that non-human animals do not have memes. In fact, I have offered some possibilities of memes in non-human animals. I have however, shown that milk-bottle opening in the British tit is not memetic, and that the existence of this behavior is not sufficient to conclude that animals have memes. Because of the diversity of cognitive ability among animals, I do not believe the question of memes in animals can be answered definitively by pointing to a few cases. Some animals may have memes while others do not. We must proceed cautiously and take a case by case approach. By doing this we will be able to construct a catalog of animals whose minds have memetic compatibility.

Memes were assimilated from the following sources:

WHAT IS A MEME?

By

Brent Silby

Department of Philosophy, University of Canterbury
Christchurch, New Zealand

Memetics is rapidly becoming a discipline in its own right. Many web-sites are being devoted to the study of memetics, and new e-papers are appearing every day. With this in mind, I want to step back and have another look at what it is we are talking about. What is a meme?

In the first section of this small e-paper, I'll get back to basics and will offer a tangible definition of a meme. I will then move on to the next section and ask "what can we do with our knowledge of memes?"

What is a Meme?

Richard Dawkins first came up with the idea of a meme in his 1976 book "The Selfish Gene". Essentially, memes are ideas that evolve according to the same principles that govern biological evolution. Think about all the ideas that you have in your head right now. They are all memes, and they all came from somewhere. Some of them will have come from friends and some will have come from the internet or television. Examples of memes are musical tunes, jokes, trends, fashions, catch phrases, and car designs. Now, the memes that inhabit your mind are in competition with all the other memes in the *memepool* (the collection of all existing memes). This means that they are all competing to get themselves copied into other people's minds. Some of these memes do quite well. Every time you whistle your favorite tune or utter a useful catch phrase, you are facilitating the spread of those memes. Every time you wear something that is "in fashion" you are helping the idea of that fashion enter other people's minds. Consider the first four notes of Beethoven's 5th symphony, or the "Happy Birthday" song. These are ideas that inhabit our minds and have been very successful at replicating. Not only have these memes found their way into literally millions of minds, they have also managed to leave copies of themselves on paper, in books, on audiotape, on compact disks, and in computer hard-drives (Silby 2000).

There is a limited amount of memetic storage space on this planet, so only the best memes manage to implant themselves. Memes that are good at replicating tend to leave more copies of themselves in minds and in other mediums such as books. Memes that are not so good at replicating tend to die out. We can imagine what sorts of memes have become extinct. Ancient songs that were once sung and never written down are one example. Another example is the many stories that were once told but have since slipped into oblivion. A Story is a vast collection of memes that have come to rely on each other for replication. Such a structure is known as a memplex. Stories are memplexes that are in direct competition with other memplexes. If a story replicates through story getting told and read by people, then it will survive. If it stops getting read, it will become extinct. Libraries are full of memetic fossils in the form of books that contain a multitude of ideas that are never looked at (Silby 2000).

You will see that memes behave in a similar way to genes. Furthermore, you will notice that like genes, memes are subject to selection pressures. Whenever you have a situation that contains a number of unique entities that are competing for limited resources, the entities that are better at reproducing will leave more copies of themselves. In the case of memetics, memes are competing for minds to inhabit, and those that are better at reproducing are those that manage to get expressed in behavior (for example, behavior such as whistling). Defining memes as ideas is standard, but it gives rise to an objection. The objection goes like this:

All this talk of memes and memetic evolution is meaningless unless we can identify exactly what a meme is. Ideas can come in all shapes and sizes, but there seems to be no way to identify their composite memes. How can we point to a memetic unit? How big is a meme? What is the difference between competing memes? How can they be distinguished from each other?

These are good questions. To further highlight the problem with memetics, consider the first 4 notes of Beethoven's 5th symphony. This is a meme that has found its way into most people's minds. But how about the entire symphony? It too has found its way into the minds of many people. Is the whole symphony a meme? And if so, then what about the first four notes? What about the first 3 notes; or the first 5 notes? Are these all memes?

The best way to think of a memetic unit is to consider it to be the smallest idea that copies itself completely while remaining intact. So the first four notes of Beethoven's 5th is a meme, but the first 3 is not. The 4th note is always there making up the memetic unit. The entire symphony is a huge collection of small memetic units -- a memplex. The memes that make up Beethoven's 5th might have been good individual replicators in Beethoven's day. Or they may have been attached to other memplexes. Beethoven's mind collected these memes and somehow they got connected giving rise to his famous symphony. Now they depend upon each other for continued replication. Of course, the question remains. What *is* a memetic unit? How can we point to a meme? What are we talking about when we say that a meme is the smallest idea that can copy itself while remaining self contained and intact? The answer to this is quite simple. Memes are essentially sets of instructions that can be followed to produce behavior. Instructions can be encoded in either:

- 1) Musical notation,
- 2) Written text,
- 3) Visible (or vocal) action,
- 4) The neural structure of the brain.
- 5) Digitized structures in a computer

A meme that produces the behavior of whistling the first 4 notes of Beethoven's fifth can be encoded in any of these systems and it will give rise to the same behavior. When a mind encounters an instruction set that produces behavior, it can reproduce that behavior by creating an appropriate neural "program". The best way to think about this is to consider an analogy in the computer world. Imagine that a robot is developed which contains a number of built in programs. One of these programs gives it the ability to write small behavioral routines. Essentially the robot can alter its behavior by writing small programs. A feature of this program is that it allows the

robot to observe the behavior of other robots and write programs that produce the same behavior. In effect, it can imitate other robots. Now, these programs are memes. They are not a part of the robot's innate behavior -- rather, they are produced by imitation. Such programs can be translated into different languages and written down on paper. They can also be transmitted to other robots who read the instructions or who imitate the behavior and write their own programs.

This is precisely the sort of process that goes on in humans. At some distant point in history, biological evolution provided our ancestors with a capacity to imitate behavior. This meant that humans could observe the behavior of others and their brains would produce the neural wiring needed to produce the same behavior. A neural wiring pattern that produces behavior is essentially a list of instructions, which can be translated into other mediums -- written language, outward behavior, or computer code. A list of behavior producing instructions is the thing that replicates and spreads into the minds of others. A list of instructions is a meme.

What can we do with Memetics?

Having a definition of a meme is one thing; doing something useful with it is another. How can we use our knowledge of memes? There are several applications for memetics. First, it can be used as an explanatory tool. Thinkers have been looking to aspects of human behavior and have been using memetics to offer explanations for why such behavior exists. Memetics can also be used explain human creations such as technology, music, and literature. Memeticists look at an aspect of human creativity and then construct a memetic history that may have resulted in that aspect of creativity. Of course, constructing historical accounts of any sort of evolutionary process is a dangerous business. Evidence is fragmentary, and it is impossible to determine the truth from the "just so" stories.

Another approach is to deconstruct a human creation -- such as a piece of music -- and discover the components that brought the creation together. By doing this, memeticists may eventually come to understand why it is that certain memes manage to attach to each other for mutual survival in a memplex. They may also discover what it is about certain groups of memes that make them such good replicators.

In addition to the above, memetics has the potential to enhance our study of psychology. In the future, psychologists may look to memetics to discover the origin of certain psychological conditions. Perhaps multiple personality disorder could be explained by the existence of two (or more) competing memplexes that each define a sense of self (Susan Blackmore (1999) calls such a memplex a 'selfplex'). The idea behind this thinking is that a human mind is basically a memetic construct. When a brain becomes inhabited by a suitable collection of memes, they form a mind and a selfplex develops. Anomalies such as psychological depression (non-physiological) or addiction might be explained by memetic viruses that influence the behavior of the selfplex.

Putting these possibilities aside, the ultimate goal of memetics should be its ability to *predict* behavior and the evolution of future memetic structures. Future memetic psychologists could use their knowledge of memetics to predict what will happen when people are exposed to certain combinations of memes. If they are successful at making such predictions, then it will be

possible to determine which combinations of memes will lead to the production of criminal behavior. Attempts could then be made to filter certain memes out of the memepool. Of course, this would open up a new debate on the wisdom of censorship and the purposive destruction of memes. Who, after all, would decide which memes to force into extinction?

Into the Future...

The "meme" meme has successfully gotten itself entrenched in the memepool. It is spreading rapidly around the human species at the speed of light, and it will one day have infected everyone's mind. Its reproductive success is a testimony to its infectious power. There is something about the "meme" meme that makes it a good replicator. It fits in well with the other memes that inhabit our minds, and there is something about it that makes us want to communicate it to other people. We are enabling its survival.

Memes offer us a way to understand our psychology and the evolution of our thoughts, technology, artifacts, music, and art. They can be defined as small sets of instructions that produce behavior. When enough of these instructions get together in a brain, a mind develops. Such a mind can be understood and predicted by looking at its composite memes. With its explanatory power, and its potential to make behavioral predictions, memetics will become an essential addition to a psychologist's tool kit. As its success increases, memetics will take over where psychology has left off, and will become a driving force in the study of human behavior.

EVOLUTION OF TECHNOLOGY: EXPOSING THE MYTH OF CREATIVE DESIGN

By

Brent Silby

Department of Philosophy, University of Canterbury, New Zealand.

Evolution of Technology...

Evolution in the biological world has been pretty much accepted. Those who once argued against it have settled down. Most people now accept that our existence is the result of an extremely long history of evolutionary process. This process is responsible for the diversity among species on this planet, and is also responsible for the development of conscious, creative human minds. In the past, evolutionary theories of biological life have been resisted for a number of reasons. One of these reasons is that it challenged our ancestor's view of themselves and humanity's place in the universe. If evolution is true, then it seems that we humans are not the result of purposive design -- rather, we are the result of an inconceivably long history of inheritance of random change. In the past, many thought this view was unacceptable. Even today, some people find the view unpalatable and insist that the human species is the result of intelligent design. Despite the resistance, however, scientific discovery has given us good reason to suppose that evolution by natural selection takes place. Fossil records, DNA analyses, and experiments with short generational span bacteria are examples of empirical data that can best be explained by evolution in the biological world (see the Lenski Lab <http://www.msu.edu/~lenski/> for experimental research on bacteria).

Does evolution remove humanity from its special place in the cosmos? It could be said that the truth of evolution does not alter the fact that humans, unlike other species, possess *creativity*. We have the ability to produce beautiful music, paint scenery, write poetry, and design artifacts. For most people, the common sense view of the human mind is that it is a source of *intellectual originality*. In addition to its artistic abilities, it can use its creativity to *design* technological devices that serve specific purposes. There are many examples of technology that has been designed to serve a specific function. Consider the watch (a well worn, but effective example). People needed to tell the time so they set about designing a timepiece. After many experiments and many design alterations our ancestors developed the first timepiece (it should also be noted that in doing so they inadvertently invented the concept of "running late", an unforgivable consequence).

In this paper, I will argue that the common sense view of the human mind is wrong. I will suggest that human creativity is a myth -- or at best, an illusion. To begin, I will outline the theory of evolution and will show that it can be applied to non-biological systems. I will then examine the so-called creative process, and will attempt to discover the mechanisms involved in designing technological artifacts. My conclusion will be that technological artifacts are not the result of creative thought -- rather, the creative process can more accurately be described as the execution of an evolutionary algorithm.

1. What is Evolution?

Let's quickly run through the theory of evolution. The beauty of evolution is its simplicity and its portability to a number of domains. Once you understand how the system works, you can see that it can be applied to several different fields of enquiry.

Charles Darwin is thought to be one of the first people to theorize about evolutionary process. His ideas were published in his famous "On The Origin of Species by Means of Natural Selection" in 1859 and have resulted in a drastic change in the way we think about our place in the universe. For such an influential theory, however, evolution is based on surprisingly few premises:

- 1) In ideal circumstances (limitless resources), populations will grow exponentially.
- 2) Resources are limited.
- 3) Because resources are limited, populations tend to remain stable.
These first three premises were formulated by Thomas Malthus in his essay on the principle of population. The remaining premises are Darwin's additions.
- 4) Individuals within a population have unique characteristics.
- 5) An individual's characteristics are passed on to its offspring (inheritance).
- 6) Change can occur, and this sometimes results in offspring having slightly different characteristics to their parents'.
- 7) Given the fact that individuals have varied characteristics, it is reasonable to suppose that *some* individuals will have characteristics that give them a better success at acquiring resources and reproducing.
- 8) Given premise 5, it is reasonable to assume that characteristics that enhance an individual's survival and reproductive success will be passed on to subsequent generations -- this is *Natural Selection*.
- 9) Evolution is the result of this process.
- 10) Populations that possess the above characteristics will evolve.

(This list has been adapted from a list provided by Herbert, T. (2000) Historical Perspective, Darwin and Evolution).

You will see that there is no requirement for the population to be one of biological entities. The above system can be applied to a number of different population types. All you need for the system to work is a population of entities that are: 1) competing for resources, 2) have unique characteristics, 3) can reproduce, 4) produce offspring that inherit their characteristics, and 5)

whose offspring might be different. This is to say that the offspring may find themselves with characteristics that their parents did not have -- perhaps through some sort of random mutation, the details of which are not important here.

In the following sections, I will compare the biological world to the world of ideas. With the comparisons I draw, I will show that technology has developed according to the above evolutionary system.

2. How do you build a watch -- or a dog?

How do you *build* a piece of technology, say a wristwatch? The answer to this is obvious. You follow a list of instructions. These instructions will tell you what sort of hardware to purchase and how to put it together to produce a functional watch. If you want to go any further and ask "why" the watch does what it does, you simply have to appeal to its *designer*. The watch tells the time because that's what its designer intended it to do. Perhaps you purchased your instructions from a company like 'ACME' (the one that supplies the coyote with road runner catching equipment -- remember the old Warner Bros cartoons). You know that a lot of very clever people work at ACME, and so you know that if you follow the instructions correctly, you will build a fully functional watch. You don't need to understand how it works, because someone at ACME has already figured it out.

But what if you had no instructions? What if you had never seen a watch before? Now, ask the same question again. *How* do you *build* a wristwatch? The answer in this case is not so easy to find. Think about it, and you will probably find yourself seeking answers that rely on the existence of earlier examples of wristwatches -- or at least some knowledge of the passage of time. You might think to yourself that you would build a watch that is something like an old grandfather clock, just much smaller. Or perhaps you will design your watch based on the timing of the sun crossing the sky -- thereby utilizing your knowledge of the rotation of the Earth. But suppose these things do not exist. Suppose you have never considered the passage of time -- perhaps the Earth does not rotate -- and timepieces have not yet been invented. In such a scenario, would it be possible to design and construct a wristwatch? I think the answer is no!

Given your lack of knowledge about the passage of time, it seems that you would not even be able to conceive of the *need* for a wristwatch, much less design one from scratch. It seems difficult to believe that someone with no prior knowledge of watches could sit down and design a wristwatch, or any other sort of timepiece. But wait. Wristwatches exist, don't they? They didn't design themselves and they did not appear out of thin air, so surely *someone* must have designed them. If not, how could we explain their existence? Was it God? Or are we missing something? Let's turn to the biological world and ask an analogous question. How do you build an animal, say a dog? If you are a scientist in a laboratory, you might answer the question in the same way as before. You follow a list of instructions. In the case of animals, the list of instructions is known as a genome. The genome is an incredibly large collection of genes. Genes are chemical instructions, encoded in DNA (Deoxyribose Nucleic Acid), that direct the development of cells. A fertilized egg will contain genetic information from both its parents, for example a male and female dog. As the egg cells divide (first into 2 cells, then 4 cells, then 8 cells, and so on), they chemically read the instructions that are contained within their genetic blueprint. These

instructions tell them how to develop. Some will become skin cells; some will become brain cells, and so on and so forth. Eventually a fetus is formed, then a cute puppy, then a fully functional adult dog.

Now let's ask the further question: *why* does the dog behave and look the way it does? Unlike the wristwatch case, we cannot appeal to a designer because in the case of dogs the idea of a designer simply does not enter the picture. Dogs were not designed. Nevertheless, it is a good question and evolutionary biologists can provide us with an answer. The dog behaves and looks the way it does because of the genetic instructions that were used in its construction. But these genetic instructions were not provided by a designer. They are the result of an incredibly long history of subtle modification of earlier instruction sets. It is important to emphasize that these modifications were not guided by an intelligent process. They were the result of random change and transmission to offspring. A rundown of the process might go something like this:

At some point in history, an ancestor of the contemporary dog existed. One day, one of these early dogs gave birth to offspring whose genetic instruction sets were ever so slightly different (perhaps because of some mutation due to something in the environment, or perhaps because the copying mechanism is not perfect). The difference may have been almost undetectable -- perhaps they had a slightly enhanced sense of smell. Now, because of their better sense of smell, these offspring were a little better at avoiding predators, finding food, and finding mates (very important for us mammals). Since genes are passed on to offspring, the change in the instruction set was reproduced in subsequent generations. Hence, dogs got better at using their noses.

An important point that is often misunderstood here is that the development of slightly different characteristics *does not necessarily lead to the extinction of animals that possess the original characteristics*. They may continue to reproduce effectively for millions of years. Furthermore, descendents of the original animal may one day give birth to something that is slightly different in other ways, and it too will pass on its features to its offspring (if it manages to reproduce, of course). And thus we get a 'branching' effect in the history of life on Earth.

Genes are the key to this system. They provide the instructions for how to build an animal. They are reproduced in offspring, and sometimes they change. The genes that get themselves reproduced effectively -- perhaps by providing a creature with a better sense of smell -- are the ones that survive. Less successful genes, for example genes that reduce eyesight in dogs, will tend to have limited reproductive success and will tend to lose their representation in the *gene pool* (the total gene set on Earth).

The explanation works well. By iterating (repeating many times) a very simple process of subtle change and inheritance, we can account for the existence of extremely complex, well adapted dogs. Could a similar answer work for technology? Can a technological artifact such as a wristwatch be broken down into a collection of small components like genes? Is it possible to account for technology by grouping large numbers of these small components together? The answer to this question can be found by appealing to the study of *mimetics*.

2.1. Selfish Memes

In his 1976 book *"The Selfish Gene"*, Richard Dawkins introduced an entity known as a *meme*. Memes are entities that primarily inhabit human minds (but you can find them in other places as well). To express it simply, a meme is an idea. Some modern day examples of memes are musical phrases, jokes, trends, fashions, car designs, and poetry. Any thought or idea that has the capacity to replicate is a meme. A well used example of a meme is the first four notes of Beethoven's 5th symphony. Another example is the "Happy Birthday" song. These are ideas that inhabit our minds and have been very successful at replicating. Not only have these memes found their way into literally millions of minds, they have also managed to leave copies of themselves on paper, in books, on audiotape, on compact disks, and in computer hard-drives. At first glance the idea of a meme may seem trivially true. Of course ideas spread, what's the big deal? Well, the big deal is that memes behave in similar ways to genes, and in this way their behavior and development can be described in terms of evolution.

Like genes, memes are in competition with each other. While genes compete for representation in the gene pool, memes compete for representation in the *memepool* -- the huge collection of ideas that are currently circulating the world. Human minds have limited room, so only the best memes manage to implant themselves. Memes that are good at replicating tend to leave more copies of themselves in minds and in other mediums such as books. Memes that are not so good at replicating tend to die out. There is a gigantic history of extinct memes, but since they are extinct we do not know what they were. To know what they were and to mention them here would only be possible if they were still circulating in the memepool. But we can imagine what sorts of things they were. Ancient songs that were once sung and never written down are one example. Another example is the many stories that were once told but have since slipped into oblivion. A Story is a vast collection of memes (a memplex), which are subject to the same selection pressures as other memes. If they replicate through the story getting told and read by people, then they will survive. If they stop getting read, they die. Libraries are full of memetic fossils in the form of books that contain a multitude of ideas that are never looked at.

The memes that replicate the best are the ones that manage to fit into existing collections of memes. Music is a great example (see Dennett (1999) for an interesting examination of the evolution of music). Contemporary music conforms to a set of rules. If a song were produced that followed an entirely alien set of rules, it would not fit in with our existing set of ideas about music and would probably die out. But if a new song appears that follows all the rules, then it will fit in nicely and will copy itself from mind to mind and to CD's, MP3's, and hard-drives. New songs are collections of memes that have been formed through the subtle change of existing memes. This change may be the result of some sort of blending of ideas or random mutation perhaps resulting from imperfect copying. The result is a slightly different song that contains memes that are competing for representation in the memepool.

An important point to note is that memes replicate for their own sake and not for the sake of the minds they inhabit. If a meme appeared that resulted in people carrying out life threatening activities, it *could* still be successful if it managed to transmit itself to other minds before its host died. Some examples of such memes might be the ideas involved in parachuting, high speed motor racing, smoking cigarettes, or taking other dangerous drugs. The memes do not care about

the danger that people face when carrying out these activities. Memes are simply reproductive entities. If there is something about a meme that makes it good at getting copied into other minds or into other mediums, then it will continue to exist. If it mutates and produces a meme that is slightly better at replicating then the new meme will compete more effectively for representation in the memepool -- an event that could lead to the demise of an older meme.

Many thinkers have resisted the idea of memes on the grounds that it is not possible to determine exactly *what* the meme is. We know that it is an idea that replicates, but how can we *point* to a meme? How can we isolate a memetic unit? This is a valid question. After all, there seems to be big differences between memes such as the first four notes of Beethoven's fifth symphony, the phrase "You're damned if you do, and you're damned if you don't", and the behavior of shaking hands. How can each of these be considered to be single memes? A similar problem arises when scientists talk about genes. There is no real gene 'unit'. Genes are packets of information that are encoded in DNA. Distinct genes can vary markedly in length. The same goes for memes. Memes are best thought of as packets of information that can be encoded in a number of different mediums. They can be encoded in the complex neural architecture of the brain, and they can be encoded in magnetic patterns on a hard-drive. A memetic 'unit' can be described as a *self-contained information packet that reproduces*. So, the first *three* notes of Beethoven's fifth symphony do not constitute a meme because it is not a self-contained information packet that reproduces. The *fourth* note is required to complete the reproductive unit. Of course, the question of the rest of the symphony now arises. Is it made up of a multitude of four note units? The answer is no. The symphony *is* made up of a vast collection of memetic units, but they are all different lengths. The entire symphony constitutes a memplex that has good replicative power, but many of the individual memes would not make it alone. Some do, however -- you often find small pieces of music reproduced in other work -- but for the most part, the memes are dependent on their counterparts in the memplex for survival. It is possible that the memes that comprise the fifth symphony memplex were common in Beethoven's day. He was undoubtedly influenced by the tunes and musical themes of his time, and these would have found their way into his work. Even though they would no longer survive on their own, they manage to survive by being a part of the large symphonic memplex that continues to reproduce.

3. Does Memetics fit in with the Evolutionary Theory?

Now, let's consider evolution's premises (see section 1 above) and apply them to memetics. Is the evolution of ideas plausible?

The first premise states that in ideal circumstances, populations grow exponentially. In the case of memetics we can see that this is true. If you have an unlimited population of communicating minds -- ideal for memes -- then the population of memes *would* grow exponentially.

Communication would ensure that the memes are continually replicated and implanted in new minds. If an idea appears in one person's mind, and she transmits it to everyone she knows, who in turn transmit it to everyone they know, you get an exponential growth in replication of that meme -- hence the memetic population grows exponentially.

Premise two states that resources are limited. This is obvious in the case of memetics. There are a finite number of vehicles for memes, which include minds, written text, pictures, and objects like wristwatches.

In premise three, we state that limited resources lead to the stability of population. It is difficult to see that this is true of memetics because the memepool is continuing to grow. New people are being born and are continuing to create new ways of storing memes. Despite this, however, the memetic population is reasonably steady. Old ideas disappear and are replaced by new ideas -- there simply isn't the room for all of them to exist and keep replicating.

Premise four is very important. It states that individuals in a population have unique characteristics. The uniqueness of memes is obvious. Some memes are similar, but others are extremely different. Consider the difference (mentioned above) between the first four notes of Beethoven's fifth symphony and a behavior such as shaking hands when meeting people. These are distinct memes with unrelated, unique characteristics. One manifests itself as a sequence of sounds, either imagined or real, while the other manifests itself as an action.

From premise four we can go on to show the truth of premise five -- that an individual's characteristics are often passed on to its offspring. In the case of the hand shake, the meme reproduces when people observe the behavior and imitate it. Imitation keeps the characteristics of the behavior intact while copying the meme into the mind of the imitator. Whether it survives in the new mind is another question that depends upon the behavior being carried out again. Of course change can occur, as premise 6 goes on to state. This can be the result of memes merging with existing memes, or perhaps because of imperfect copying of the original meme -- sometimes stories change; sometimes behavior is not imitated accurately. Such changes give rise to new memes that compete to get them selves expressed and reproduced.

This brings us to premise 7, which states that some individuals will have characteristics that give them a better success at acquiring resources (minds, paper, hard-drives) and reproducing. Some memes enter minds and get stuck there -- never finding a way out -- until they degrade and disappear. Consider, for example, a joke that you might have heard several years ago. It's memetic structure copied itself into your mind, but for some reason it did not compete well with the memes that were already there. Consequently it never found an outlet. There was always something else that was more important to say -- more successful at reproducing. Eventually the joke's memetic structure degraded and faded away. Fortunately for the joke, many other people probably *did* utter it, and its propagation continued in the minds of others. But this is not always the case. There is an enormous history of memes that were once effective replicators but eventually died out because they could not compete with other memes. Old songs from the second century were probably very good survivors, until they were eventually replaced by memes whose characteristics that enhanced their own reproductive success.

Now, given the fact that a meme's unique characteristics are passed on to its descendants, and given the fact that only the best survivors get to reproduce, we can assume that characteristics that enhance reproductive success will appear in subsequent generations. This process, as stated in premise 8, is known as *Natural Selection*.

The result of the process outlined here is memetic evolution.

Now that we have a definition of memetic behavior, and given the idea of what constitutes a memetic unit, we can turn our attention back to the development of the modern wristwatch.

4. A Brief History of Timepieces

Deep in our history, humans had very little understanding about the passage of time. We can suppose that their only real knowledge of time was that when it got dark, they went to sleep. This sort of behavior is innate and so does not fall under the category of memetics. One day, however, a human might have accidentally discovered a new use for watching the sun. This primitive person might have realized that lions and tigers do most of their hunting at dusk. If this happened, a new behavior would probably have emerged -- a behavior that would have led this intelligent person to seek shelter when the sun reached a certain position in the sky. Now humans, unlike most animals, have the ability to acquire new behavior through *imitation*. When members of the group noticed their friend seeking shelter in response to the changing position of the sun, some would have copied that behavior, thus giving rise to the transfer of the '*action at a specific time*' meme.

As the centuries passed, more time dependent behavior would have surfaced. The behavior that copied itself into the minds of many individuals tended to continue reproducing, while behavior that stopped occurring did not get imitated and eventually died out. Looking at the position of the sun to determine what action to take is a behavior that was very successfully copied into the minds of most of the human species. Eventually the 'look at the sun meme' mutated. Somehow it got merged with other ideas that were circulating, and gave rise to an idea that involved looking at the shadow of a stick for a more accurate impression of the passage of time. In time, the 'look at the shadow of a stick' meme was influenced by other memes that were appearing and developing at an exponential rate. Memes for constructing items out of stone and memes for using symbols to represent different times of the day, blended with the 'look at the shadow of a stick' meme to produce new memes that eventuated in the construction of the *sun-dial*.

Later in history, a gigantic collection of memes were at work producing mechanics and devices that were made from moving parts, like the water wheel and the windmill. Through some incredible combinations of memes, the mechanical memes became attached to the sun-dial memes and produced the first clock. A huge number of variations of the clock appeared prior to the appearance of the modern wristwatch. Ideas were adjusted as they were influenced by other ideas, and this process led to the refinement of the clock. Many early versions did not work very well and were not reproduced. Memes that led to the failure of early clocks did not appear in later versions and subsequently became extinct.

The modern wristwatch can be described as a collection of successful memes -- the ones that survived. When a watchmaker builds a new watch, he/she is not 'creating' or 'designing' something from scratch. He/She is pulling together a bunch of memes that have slowly evolved since the first humans noticed the sun's movement across the sky. The modern wristwatch owes its existence to the gradual evolution of memes -- an evolution that was driven, in part, by trial and error experiments on existing memetic constructs.

5. A Concluding set of Memes

I have attempted to show that the idea of creative design can be replaced with an evolutionary picture. The basic premises of evolutionary theory are not exclusive to the biological world, and can therefore be applied to other domains. In this paper, I have run through a description of memetics, and have shown that memes (or ideas) evolve in a similar fashion to genes. My aim has been to show that technological devices, such as the wristwatch, are a collection of memes that have evolved over the course of human history. If the assumptions I have made are correct, and if evolutionary theory is correct, then it seems that human creativity can be replaced with memetic evolution.

The human mind is full of memes that are competing for resources. The most effective memes are those that get themselves reproduced. So, in the case of the wristwatch, we can suggest that the designer's mind was buzzing with memes relating to previous versions of timepieces. Some of those memes were very good at getting themselves expressed, and in doing so, found themselves incorporated in the design of the wristwatch. The memes that were not so effective at getting expressed (for example the idea of attaching the watch to one's jacket via a chain) were not included in the new design and are now dying out.

Where did these wristwatch memes come from? Well, they originated deep in human history and looked much different than they do today. They jumped from mind to mind through the process of imitation. Sometimes they would change ever so slightly; perhaps by being influenced by other memes, or perhaps through imperfect imitation. Thousands of years of memetic transfer resulted in the memes that comprise the modern wristwatch. It was just a matter of time before they all accumulated in one mind, and the wristwatch was born.

Mememes were Assimilated from the Following Sources:

A SHORT COMMENT FROM A BIOLOGIST ON WILLIAM BENZON'S ESSAY "CULTURE AS AN EVOLUTIONARY ARENA"

By
Hans-Cees Speel

Graduate Research Assistant, Dept. of Policy Analysis, Delft University of Technology,
Jaffalaan 5 PO Box 55015 2600 GA Delft, The Netherlands. E-mail hanscees@hanscees.com

This article is published in the *Journal of Social and Evolutionary Systems*, 20 (3): 309-322

Introduction

Many biologists have written on issues of cultural evolution from the 'memetic' point of view. The starting-point for their theories is the definition of both gene and meme as replicators. If we indeed value new classifications and theories more when they are connected to other, generally accepted theories, then cultural evolutionary theories which include memetic views have potency. Evolutionary theories in biological sciences are accepted, and the memetic view is strongly analogous to the structure of those theories. However, memetics cannot grow without serious attention from non-biologists studying cultural evolution. Therefore, I was happy to see William Benzon's essay integrating the memetics view on cultural evolution with views from other disciplines. Benzon's article focuses on cultural evolution, drawing examples from biological evolution for comparison. In this short reply, I shall present ideas formed in biological theory with regard to the meme-gene analogy.

My reply concerns four issues. (1) I will negate the statement that biologists agree that classification should reflect phylogeny. (2) I will comment on the examples Benzon uses with respect to biological evolution. I will argue that the view that only species can be considered evolutionary systems is too limited. (3) I will expand on the use of the concept meme as a replicator, introducing concepts as interactor and selective retention system. (4) I will reply to his view on the genotype-phenotype concept. I will argue that his use of these concepts is incompatible with the replicator view as used in biology. (5) A final remark concerns the comparison Benzon makes between the complexity of cultural and biological evolutionary systems.

1. Biologists, classification and phylogeny

The first issue I would like to challenge is that all biologists agree on the view that taxonomic classification must reflect phylogeny. This means that classification trees should reflect descent. Hull's (1988b) book *On the social and conceptual development of science* shows that not all biologists hold this view. The views of different schools that do not hold this view vary from acknowledging evolution as important, but not a practical base of knowledge on which classification can be based, to the view that classification is a discipline with its own value regardless of evolutionary theories. Benzon refers only to those that do hold the view that taxonomic classification must reflect phylogeny, for instance Mayr, leaving out members of other schools of thought.

2. Biological evolutionary theory and species

Benzon uses species as the sole example of biological evolutionary theory. However, Hull (1982, 1988a, b) states that although species might be the 'paradigm example' of evolution by natural selection, we are biased in this regard. Species are by definition sexually reproductive units, but most organisms reproduce asexually and cannot be classified as species per se. Examples are bacteria, viruses, and many plants and lower animals. Thus, only to speak of species as examples of evolutionary biology is not representative of empirical reality. Asexual reproduction is very important in biology. Borrowing is more common in the asexually than in sexually reproducing organisms. Therefore, it must not be overlooked in the discussion of the prevalence of borrowing in biological and cultural evolution.

In biology, viruses can transmit genes over lineage-boundaries, and in bacteria plasmids are exchanged between strains. Benzon mentions that some plant species may mix their gene-pools and that animals now also are suspect of this. Because borrowing is so extensive in 'lower' organisms biologists often cannot use the classification rules that were developed to classify species. Based on these observations I want to assert that cross-lineage borrowing (Campbell, 1965), or multi-parental transmission (Boulding, 1978; Boyd and Richerson, 1985) are not a difference in kind between cultural and biological evolution. As Hull (1982) states, the only difference in kind between biological and cultural evolution is intentionality, and currently I think he is right.

3. Evolution, replication, interaction and selective retention

Benzon uses the concept meme from Dawkins (1976), and also states that physical memes are dispersed. By saying this, he seems to accept Dawkins' view of memes as replicators. Replicators are units of information that are copied, or in other words replicated. However, replication alone cannot describe evolution. Hull (1982, 1988a) has expanded the replication concept with processes of interaction. Together with interaction, replication can generate evolution by either natural or artificial selection, be it intentional or not. Selective retention systems (Campbell, 1974), sexually reproducing or not, show adaptation because there is interaction and thus selection. In cultural evolution this expansion of the interaction concept to the replication view does not always play a role, while in biological evolutionary views selection is almost always pre-supposed (Speel, 1996). Using this elaborated abstract view on evolution the following sentences of Benzon can be amended:

'I take it that the first requirement for understanding culture as an evolutionary domain is to find suitable parallels to the biological concepts of gene, phenotype, environment, and species. We need something like the genes to vary, be replicated, and passed on from generation to generation. We need something like the phenotype to adapt to the cultural environment. And we need something like the species to bear the collection of genes which creates the adapting phenotype'.

This becomes:

I take it that the first requirement for understanding culture as an evolutionary domain is to find suitable parallels to the biological concepts of replicator, interactor, environment, and retention system. We need replicators to vary, and to be passed on from generation to generation. We need interactors to compete in the cultural environment. And we need something like a retention system to hold the collection of memes and in which adaption can take place.

The beauty of using the concepts replication and interaction in biological evolutionary theory is that it allows us to omit the view that evolution is restricted to species, and to describe evolutionary mechanisms in general. It has led to an hierarchical view on evolution (Brandon, 1988) where both asexually and sexually reproducing organisms can be described in the same theoretical framework. In biological evolutionary theory, replication is used together with interaction to describe evolutionary processes. I suggest that we do the same in cultural evolutionary theory. The biological parallel of the replicator gene is the replicator meme which is passed on from generation to generation, but also from human to human, or from culture to culture. Of course, it is not the phenotype which adapts itself but the selective retention system. In theories concerning humans, such systems can be the mind or a society, but also an organization or a discipline in science. Accordingly, phenotypes can be represented as traits, ideas or physical artifacts which interact in selective events. In other words, a phenotype is the element that interacts with the selective environment. The next section elaborates on the genotype-phenotype distinction.

4. The genotype-phenotype distinction

Benzon proposes that psychological traits in the brain form the phenotype in memetic evolution, and that physical memes should be seen as the genotype. Several other authors have written about the phenotype issue (Plotkin and Odling-Smee, 1982) and about what the phenotype should consist of in memetic evolution (Heyes and Plotkin, 1989; Hull, 1982). I would like to use the replicator-interactor-lineage model to explain my point of view. In my terminology the memetic counterparts of genotype and phenotype are respectively, the "memo-type" and the "phemotype". Even though Benzon does use the meme concept by Dawkins, he denies that memes can be located in the brain (Benzon, pers. comm.). These two views are inconsistent. Dawkins defines memes as replicators. Following this line of thought, memes should be defined as any unit of culture that is copied, be it from human to human, from culture to culture, or otherwise. Benzon's physical memes do get dispersed over cultures and thus they comply with Dawkins definition. However, I think memes in the brain are replicators as well. In my view, it is clear that ideas, songs and norms reside in the brain somehow, as they are copied as units from human to human, but also from brains to books, or to physical air-waves. These observations of replications define them as memes that are located in the brain. Thus I argue that under the definition which makes physical memes replicators, brain-memes are also replicators. The view that brain memes are units of evolution is consistent with Dennet (1991) and Lynch (1996).

Benzon considers physical memes to be the memotype, and psychological traits to be the phemotype. I think that this division is not correct. In biological theory, genes are replicators that do not interact with the environment. Almost all replicators in biological theory are genotype. Traits or parts of the phenotype are the structures that are decisive in interaction. Thus in biological theory, interactors belong to the phenotype, and replicators to the genotype.

Interaction takes place with regard to the selective environment (Brandon, 1988). Unless there are severe reasons not to, the theoretical connections between replicators and genotype and interactors and phenotype in biology, should be followed when defining equivalent concepts in cultural evolution.

By definition, environments are considered to be selective if there is a kind of competition or weeding out. In compliance with Benzon's terminology, we could call a selective environment also an arena. In biological evolution, species are subject to selective processes in many arenas.

Sperm-cells compete for egg-cells, males compete for females, females and males compete for their genes to be reproduced, genes involved in "meiotic drive" can compete by intra-cellular traits for replication into sex-cells (Ridley, 1993). Thus many arenas can be distinguished in which many selection processes take place, possibly at the same time. I see no reason why cultural evolution cannot be described with multiple arenas as well. Physical and brain memes can be replicators and they can both interact in different arenas. However, when they interact they should be considered phenotype, and when they are replicated they form the memotype. When Benzon states that psychological traits in the brain are phenotype this means by definition that parts of those traits can serve as interactors. I am not quite sure what Benzon considers psychological traits to be, and if he means that those traits are interacting. But I do agree that a "trait" like an emotional attachment to norms is not copied directly and thus cannot be considered to be a meme.

In the preceding paragraphs I have taken the view that memes in the brain can be interactors but also replicators. This is because replicators and interactors are definitions of process. The very same norm, or dispersed idea, can act as a replicator in one case and as an interactor in another. Norms are dispersed among humans by replication, and sometimes replicated from culture to culture. But ones established in a culture, these same norms can prevent other norms from entering the culture of which they have become a part. In this example such norms act as replicators first, and then as interactors, which compete with new incoming norms. In summary, Benzon's proposal that psychological traits are phenotype, and physical memes are memotype seems to be inconsistent with the underlying definitions from biological evolutionary theory. It is the role cultural units play in the evolutionary process which determines if they should be considered one or the other.

5. Is culture a more complex phenomenon than life?

The very last issue I want to address is a small one, but one I have seen many times before. Therefore I would like to comment on it. Benzon states in his last paragraphs:

If cultural taxonomy is more complex and various in structure than biological taxonomy, that is surely because culture is a more complex phenomenon than life. Memes and traits flow between paradigms more freely than genes and phenotypes flow between species. Abstract cultural space is richer than abstract biological space.

I do not know if cultural taxonomy is more complex than biological taxonomy and do not think that phenotypes can flow between species. However, the next sentence seems to be the common

belief of non-biologists: 'Culture is a more complex phenomenon than life'. Sometimes I hear statements as 'human processes are more complex than biological processes'. I can only hope these are not seriously meant. My critique follows several lines. With regard to method, the measurement tools must be indicated when we make comparisons. Can we compare the evolution of culture and biological evolution with the same measurement device? If we cannot, the statement above is useless. Second, what is this 'life' that is being compared? And should we regard the evolution of one species more complex than the evolution of a culture? Or than the evolution of multi-species systems, or the evolution of eco-systems? Is a handful of soil with millions of bacteria that react to micro-climates and belong to thousands or more strains less complex than the evolution of culture? I do not support the statement that culture is more complex than life, but would be interested if anyone would attempt to compare this in a useful and valid manner. My interpretation of Benzon's statement is that culture is a specific domain of research; that intentionality is more present in culture than in biological objects of research; and that language with words, concepts and logic found in human interaction is not present in the objects of biological evolutionary research.

Conclusion

In conclusion, part of Benzon's article is an attempt to compare cultural and biological evolutionary processes. He states that we have a long way to go doing this and I think progress can be made. The integration of the concepts replicators, interactors and selective retention systems can be useful in the study of cultural evolution. If we want to make the effort worthwhile, it would be wise to involve both cultural and biological scientists and their insights. I fully agree with the last statement of Benzon:

We have plenty of good work yet ahead, and a measure of pleasure as well.

Acknowledgements

I thank William Benzon for his valuable critique on earlier versions and Martine van der Ploeg for improving my English.

Summary

Dawkins (1976) defined memes analogous to genes as replicators, and rightfully so. However, it is not generally mentioned and thus probably often overlooked that memes can also be interactors. Both interaction and replication is needed to explain natural selection (Hull, 1988b). Memes, but also genes are interactors if their direct characteristics count in selective events. Hull (1988a) mentions humans as interactors in memetic evolution, not memes. I argue (Speel, 1997) that if we can and do judge memes by their merits without necessary interference of the physical world, which implies a kind of phenotype or conceptual phenotype, memes should count as interactors. If we take the definitions of Hull and Dawkins seriously we cannot deny this conclusion.

Introduction

Memes are replicators by definition, in analogy to genes. This is the common denominator in memetics, and it is recognized by most writers on the subject. Dawkins (1976) started the definition of memes in this way, and where memeticists differ in opinion on what should count as phenotype-genotype distinction (see Hull, 1988a for some opinions) and even on what memes are (see Benzon (1998) versus Speel (1998)), they do agree that memes are replicators.

A large part of memetics focuses mainly on the dissemination part of memetics that is directly related to replication. The meme as thought contagion is a well-known view that focuses mainly on memetic processes of dissemination. Aaron Lynch's *Thought Contagion* (1996) is perhaps the main work giving the meme such connotations. Of course memes may be rightfully seen as disseminating through human systems, but this view alone cannot account for natural or artificial selection involving memes.

Any theory accounting for adaptations by natural or artificial selection must include processes of interaction (processes such as competition and predation in biology) and processes that account for new variation and possibly the re-combination of old variation. I have argued before (Speel, 1996) that memetic theory such as proposed by Dawkins (1976) does not make it clear if meme-complexes such as religions have adaptations and thus adapt. Worse, it does not provide us with possible mechanisms for such adaptations. The same can be said for the work of Lynch (1988) on religion that also lacks explanations on how religions as meme-plexes (co-adapted meme-

complexes) somehow incorporate adaptations, by which some religions become more successfully disseminated than others.

This lack of focus on adaptations and mechanisms perhaps explains why memetic theory has only incorporated that memes are replicators, but not that memes are interactors.

In the following pages I shall argue that memes are by definition replicators, but that in 'internal' selection they can be interactors as well. This view is consistent with the view that RNA selection is possible where there are no translation steps such as from DNA to RNA to enzymes (Calvin, 1997). Hull's (1988a) view that genes can be interactors as well is also consistent with this view.

If memes are taken to be interactors, consequences follow for the discussion on what the phenotype must be in memetic evolution. I shall argue, contrary to Benzion (1998), Hull (1988a) and others, that memetic (sometimes vicarious) selection implies two kinds of phenotypes.

Memes can be interactors

Replicators in biological evolutionary theory were introduced by Dawkins (1976) and have become part of the received view on natural selection. Hull has argued that if the theory of natural selection is to be described fully, interactors are the necessary counterpart of replicators. Hull (1980) applies the following definitions in biological evolutionary theory:

Replicators, or the 'structural entities that are replicated', pass on their structure directly from generation to generation. In principle replicators can only replicate themselves, but they can also produce entities that interact and this indirectly results in the replication of the replicators (by reproduction). These entities are known as:

Interactors: 'entities that directly interact as a cohesive whole with their environment in such a way that replication is differential'.

In the paradigm example of evolution by natural selection, a sexual reproducing species, the paradigm replicators are the genes and the paradigm interactors are the organisms. Hull argues that replication or interaction alone cannot account for evolution by natural selection, but that both processes are needed:

Selection becomes defined as 'a process in which the differential extinction and proliferation of interaction causes the differential perpetuation of the replicators that produced them'.

Lineage is the third term in the Hull scheme and refers in this case to the historical changing entity called the species. Notice that Hull thus takes selection to be more than just 'weeding out'. For him selection refers to evolution by selection on replicators that form lineages.

Interactors play an essential role in biological evolution theory as counterpart of replicators. Brandon (1988) sees organisms, genes, groups and taxa as interactors in hierarchical levels of interaction. It might be noted that different stadia in reproductive cycles often amount to interaction in different arenas: sperm-cells usually compete for a few or only one egg cell; genes in meiosis can compete for inclusion in the sexual cells (meiosis-distorters) and so on. Beyond

this, there is probably also interaction between DNA in chloroplasts and other cell-organelles (Eberhart, 1980). It should be noted that some (Dawkins, 1982) use to prefer the concept 'vehicle' in stead of 'interactor'.

The interactor-lineage-replicator scheme as defined above, can and is used in memetic evolutionary processes with only minor changes to the definitions (Hull, 1988b; Speel, 1997). The question then arises what the interactors should be in memetic evolution, since it is of course clear that the replicators are memes. Hull (1988b) has argued that humans in memetic processes are interactors, although he later mentions that humans are agents of some sort in memetic evolution (1988a). He consequently holds memes not to produce interactors since of course humans are not produced by memes (1988b).

Human individuals can indeed be interactors in memetic evolution, but I have argued before (Speel, 1997) that memes can also be interactors in 'internal' interaction or selective interaction (s-interaction). [Footnote: I prefer 'selective-interaction', or 's-interaction' to just 'interaction' because this circumvents the confusion with 'interaction' in social sciences that usually means something like 'individuals reacting in some way to each other'. S-interaction implies a result in differential perpetuation of replicators.] Internal selection is selection inside a mind when someone makes up his mind on whether A or B is better, true, more important, or something equal to such criteria [footnote: Note that this is not the same as a decision to remember or to notice something. It is quite possible to know something, and not to agree with it.]. External interaction is interaction where human individuals are the interactors. In external s-interaction human individuals do not question memes themselves in their minds, but they defend memes against other human individuals that act to discredit the same memes. When humans thus in practice act to defend a meme, the interaction is more directly between humans, and not directly between memes. While this internal and external difference of s-interaction might seem far-fetched it is needed to make memetic terminology suited to describe internal selection. If only humans can be interactors in memetic evolution, which Hull seems to propose, there is simply no way to describe whatever factors inside a brain, or making up a mind, are responsible for the selection of ideas. Such factors might be called installed complexes of memes (Dennett, 1991), or a self. I think memetic theory ought to describe the internal selection of proposals, theories etc. which we all witness in our own minds, but that we can also verify in other ways, for example by the study of verbal and other behavior.

Interactors are part of the phenotype

However, if memes are replicators, can they also be interactors? Can the same entity that is a replicator be an interactor? Can an entity that is code, geno-or memotype, be part of the pheno- or phemotype?

First of all replication and s-interaction are definitions of process or in other words functional definitions (and not structural definitions). If I use a chair to sit on, it is a seat, when I use it to hit someone it might be called a weapon. In principle words like interactor and replicator are definitions of process. The role an entity plays or has played in a process at a specific time and place is decisive for such a definition.

Memes can thus not be excluded from the interaction roles by definition a priori. In fact genes and RNA are also said to be both interactor and replicator. Hull (1988a) acknowledges that genes can be interactors, and Calvin (1997) mentions research on RNA:

"Weismann's genotype-phenotype distinction in biology is not a necessary condition for a Darwinian process, as recent experiments on "RNA evolution" have shown (there isn't a body that lives and dies, carrying the genes along, but rather patterns directly exposed to environmental selection). Envelopes such as bodies (phenotypes) are an example of stratified stability; they nicely illustrate why strict one-trait-at-a-time adaptationist reasoning is insufficient."

Calvin thus argues that parts of RNA, at least in experiments, can be both interactors and replicators.

Parts of DNA are usually not interactors: either a body of an organism or enzymes are the interacting entities coded for by the DNA. However, in some instances the direct physical characteristics of DNA might be decisive in s-interaction: Eberhart (1980) mentions the hypothesis that the size of DNA molecules might be of importance in DNA selection in cell-organelles. DNA would be s-interactor if there was selection on the form of DNA molecules, the stability of them, for instance in a high-temperature environment and so on. In RNA evolution RNA could be interactor if the chemical groups of the RNA-molecules are involved themselves in processes that are decisive for their survival.

We have seen that replicators are also allowed to be interactors because these concepts are definitions of process. We have also seen that genes and RNA can fulfill both roles. The conclusion must be that there is no reason why memes cannot be both replicators and interactors. Notice that the general evolutionary terminology of geno- and phenotype can be caught in the following definitions:

- An entity is part of the phenotype if it is directly subject to selection.
- An entity is part of the genotype if it contains a kind of code, and is replicated
- For memetics we can simply substitute pheno and geno with phemo and memo, and we have the memetic definitions:
- An entity is part of the phemotype if it is directly subject to selection.
- An entity is part of the memotype if it contains a kind of code, and is replicated

This leaves us with a problem: why should human individuals be the only interactors in memetic evolution as Hull (1988a) holds? If theories are tested, or only small parts of them, should not the theories be the s-interactors? Hull does speak of conceptual phenotypes (Hull, 1988a), but of scientists as s-interactors. I think that if characteristics of a theory describing reality are the decisive things that make a theory rejected or not, the theory (or a part of it) is a s-interactor. If the academics proposing the theory would be the interactors, they would be candidates for weeding out. Of course scientists can be s-interactors: they might socially become isolated, not respected, ridiculed or even released from their duties, which can count as a kind of social weeding out. But the weeding out of scientists would be a very different matter from the weeding out of the theories they defend. Ultimately scientists and the theory they defend might be weeded

out together, but this need not be of course. I think we need to be able to differentiate between the two selective processes, and the difference between internal and external s-interaction makes this possible.

S-interaction and vicarious selection

Memetic evolution largely goes on within people's heads. Most memes never become accepted by the mind they are at some moment being reviewed in and get forgotten or are remembered as not being useful, untrue, and so on. Memes, being descriptions of situations, solutions, problems, opinions and so on can play a role in the behavior of human individuals and organizations. In such a view, memetic evolution inside people's minds is vicarious selection (Campbell, 1974), 'producing future' on behalf of the individual or organization involved. It is true that the behavior individuals and organizations show is part of the phenotype of the individual human or organization. When descriptions of such behavior are vicariously pre-tested in the mind of someone, against a virtual model of the real world, this is a test too. It is virtual in the sense that the test stands for something else, a possible action in the real world, but it is a real test in the sense that something is rejected in someone's mind. Even if memes are internally tested without having an effect on human behaviour, it is still a selection- or weeding-out event. If memes are thus internally selected, they are phenotype (or conceptual phenotype), and thus interactors.

Conclusion

Memes are usually defined as replicators, and rightfully so. However, memes can also be tested inside minds, which makes them interactors. Human individuals can also be interactors in memetic evolution if they 'defend' memes in their struggle to be considered true, useful and so on. If a power struggle in for instance politics results in one party dictating policies, the party (or the party members) was (or were) the interactor(s), not the memes. They too won, but through selection of the party (members).

If memetic theory is to include explanations of why specific memes win from other memes, the focus on only the dissemination and replication of memes must be widened. Interaction of memes and humans must be included amongst other things, to explain both adaptations of meme-plexes (co-adapted meme complexes), and adaptations of human and organizational behavior by means of vicarious memetic evolution.

ON MEMETICS AND MEMES AS BRAIN-ENTITIES
A commentary on Gatherer's paper: Why the 'Thought Contagion' Metaphor
is Retarding the Progress of Memetics

By

Hans-Cees Speel

Derek Gatherer argues quite strongly against memes defined as brain entities and for a memetics that sees memes as cultural artefact-replicators, including texts, parts of texts and so on (Personal communication). He argues that only memes as artefacts can be observed directly and that memetics is retarded by the use of the brain- entity definition. In doing so he refers to me (Speel, 1997b) as a user of the orthodox Dawkins B definition or of a close relative of that definition. I will argue that his claim for memes as cultural entities is valuable, but his dismissal of the meme as a brain entity is not. I will also show that his reference to me is not entirely correct: my definition of a meme is meant to allow both memes as brain entities and memes as cultural artefacts, where both can be member of identical memetic lineages.

Before I will start with the points above I want to thank Gatherer for his thought-provoking article. Although I do not share all his conclusions, I do share the care for analysis of the definitions memetics uses coupled to the question how memetics as a scientific endeavour can advance (A while ago in (Speel, 1997a) I commented on a paper by Bill Benzon (1997) in which he reached conclusions similar to those reached by Gatherer). However, it was only after having read Gatherer's paper that I realised properly that the memes I study in public policy are in fact almost always texts and phrases, and not brain entities. Most of the memes that show up in empirical studies in JoM-*EMIT* are cultural entities or Dawkins A memes as well.

However, I can see no evidence that memes seen as brain replicators halter the memetic endeavour. I think that memetics must include more empirical study. Therefore a better involvement with scientists that study cultural memes would be positive. In this regard I agree with Gatherer, who implicitly claims that memetics needs to include more empirical study.

However, I do not think that disregarding the meme as brain entity will help us at all. The meme as a brain entity is needed for the simple reason that cultural entities, like words in texts that function with specific meanings, have no meaning without referral to these brain entities. What makes a vase a vase is that humans think it is a vase. A vase can only be replicated if people do this replicating (or their machines). In other words, the replication of a cultural replicator can often not be described properly without describing some brain entity form of the same replicator.

To take another example, if words in texts that we grant to be concepts are only replicated after giving them thought, we cannot overlook the part of replication where the word is a brain entity. The word in the text replicates into the brain, making the brain entity and the word direct

replicators in the same lineage. Therefore memes as brain entities must be included in memetic theory, even though empirically we will often only see the word in the text. Moreover, memetic cultural entities cannot be explained or defined without the notion that they are replicated with the involvement of (human) brains, or have been in the past.

Derek's arguments against memes as brain entities seem to boil down to mainly one thing: memes as brain entities are hard to define properly. I agree with that concern but not with his conclusion. There are two arguments I want to put forward.

First of all, there are also problems with definitions of memes as cultural artefacts. As an example I can refer to the analogous entity gene that to this day is defined in different ways in different fields. It is well known that the gene as used by Dawkins (1976) comes from G. C. Williams and is not the same as the referral to a gene as a piece of DNA that codes for a protein for instance. More directly relevant, Susan Blackmore (1988) has very recently shown that there are 'problems' with the definition of behavioral memes as well.

Secondly, I think that many problems with the definitions of a meme as a brain entity can and will be solved. Just stating that there are problems, such as the question if beliefs are memes, does not qualify the conclusion that they cannot be solved let alone that the question should be abolished. I think the question on what kinds of beliefs are memes or not needs an answer. The same argument is valid for the question if memes as brain entities can be measured. Measuring what people believe or think might be difficult, but not impossible. Surely the measurements take place in indirect ways (by interview for instance), but that is perfectly valid. I would think that many measurements in physics are not direct either: how direct are sub-atomic particles measured? Examples like the ones with the Windsor knot just show that the relation between cultural entities and brain entities is a complicated one so that we must be careful with our definitions and analysis.

Another argument against memes as brain entities is that people do not have memes, while organisms do have genes. Gatherer refers to this notion as the meme-host duality that he claims is wrong. I find it hard to reply to this argument because I do not understand the sense of it at all. It might be my lack of understanding of the English language, but because Gatherer puts so much emphasis on this argument it does need a response. I fail to see in any way that saying that 'people have memes' is wrong. It is just a manner of speaking as far as I know. Just as there is a duality between genes having organisms and organisms having genes, there is such a duality between memes and people. People can have memes, like I have knowledge of the word democracy and its meanings, and I also adhere to the values of democracy. This does not mean that memes like a style in pottery that spreads cannot be studied. I fail to see any problem. Perhaps Gatherer tries to show that the spread of memes cannot always be measured by referring to human individuals alone. There are many ways in which memes have a social status unrelated to specific individuals. Official reports of governments and concepts in it are such memes that are difficult to measure with referral to human individuals alone. But this does not qualify his strong conclusions at all.

According to my arguments above it might become clear that I see memes as replicators that can form lineages from artefacts to brains and so on. If I see a cultural entity like a Windsor knot I

might want to learn how to tie it, and ask my mother or father to show how to do this. When I noticed the knot and realised there were specific knots and that a specific one was called the Windsor knot, the cultural entity was replicated to my brain. After I have learned it, I had mastered the complex movements needed to tie the knot, and the tying-meme had replicated from the body of my parents to mine. Not a simple replication, but a replication nonetheless. I may forget all the things needed to learn the tying-patterns, but I do still know how to tie it. If we look very hard, the knot itself became (and was already) a meme when I noticed it, but the tying pattern another one. Often the analysis of memes is difficult, but not impossible. Often a memelineage 'jumps' from brain to cultural artefact. This cannot be ignored and therefore memetic theory needs to incorporate memes as brain entities.

The definition (Speel, 1997b) of memes I previously used is: '*pieces of data that are a) copied from individual to individual without too much alteration, or B) that are interactors*'. I cannot blame Gatherer for thinking I probably dismiss memes as cultural artifacts, since my definition does not mention them at all. The empirical matter I discuss in my papers however makes clear that I use texts and concepts in texts as memes. I do think however that a cultural artifact is only a meme if it has been replicated by a brain in its past. I do not mean to say that this definition will do in any circumstance, but it will in my research.

In conclusion I think that the current discussion is important. I hope memeticists become more aware of problems of definitions, but I also hope that they do not let such issues stop them from empirical research. I have argued that Gatherer's arguments need attention, for instance the question of the status of beliefs in memetic theory. However, narrowing the meaning of meme to a cultural replicator only seems unnecessary and counterproductive to me.

A MEMETIC ANALYSIS OF POLICY MAKING*

By

Abstract

A memetic framework is presented for the analysis of policy making. This framework is based on three concepts from modern biological evolutionary theory: interaction, replication and lineage. The framework consists of a view where descriptions of actions and people endorsing them, compete to get these action proposals into policy plans. This framework enables the inclusion of rational, non-rational and other selection forces, having their effects when choices are made. Because it also deals with the historical legacy of the ideas used to formulate a policy, it expands on the concept of 'bounded rationality', limiting the role of rationality or reasoning in making choices even further. It is argued that the degree of replication, versus rational or intentional deliberation in memetic evolution can yield interesting hypotheses. 'Weaseling', a mechanism for memetic variation production, is introduced as a new difference between genetic and memetic evolution. Levels of retention are introduced as differences in success criteria for memes.

Keywords: Evolution; Policy Making; Meme; University; Organization; Selection;

1. Introduction

This paper aims at establishing a memetic framework of definitions with which policy making in public and private organizations can be described and studied. We argue that the framework is useful because it systematically uses the language of the evolutionary paradigm. In doing so, this paper connects memetic theory with theory about public policy, and so establishes a link between biological evolutionary theory and theory of public policy.

The framework establishes a view of public policy processes that puts the importance of 'conscious' and intentional reasoning into perspective. As Price rightly (1995) [23] points out 'Companies are not only systems created and controlled by those who manage them but... an organization can be seen as a product of the meme'. This view is taken up and elaborated upon by considering policy processes to be memetic selective processes⁹. Rational, non-rational and other selective forces are looked upon as possible explanations in policy making. It is argued that the memetic view presented establishes an elaboration on and is complementary to the widely accepted concept of 'bounded rationality'¹ (Simon, 1976) [26].

Much has been written on memetics. However, clarity of definitions and a clear reference to specific cases are not often part of what has been written. For instance Price (1995) [23], while

writing about 'organizational memetics', comes up with very few definitions, and when he does they are vaguely defined while their usefulness is sometimes doubtful (he defines meme as 'mental model' for instance). Other confusions arise when levels of retention are not distinguished (see section 2.4).

The authors feel that clarity of reasoning is dependent on clarity of definitions, and that considerable progress in memetic theory can be achieved by this. While assessing the plausibility of (hypo) theses and the review of different mechanisms are important to progress in theory, it depends on defining clear concepts. Hypotheses must be conceived first, and can only be meaningful if underlying concepts are clearly defined. One example in biological evolutionary might be the 'levels of selection' debate which was at least partly resolved by discerning replication from interaction (Grene, 1989) [12]. We argue that, in memetics, concepts are often still unnecessarily ambiguous and that thus the establishment of clear definitions is important. Therefore this paper aims at providing such definitions in the form of a framework upon which further research can be done, pointing out difficulties where they arise.

The definitions are based upon modern biological evolutionary theory according to Dawkins forthcoming a, b) [27]. Policy processes are viewed as memetic evolutionary processes. Memes are 'pieces of data that are copied from individual to individual without too much alteration'. In fact, memes can range from simple ideas (or concepts), to complicated ways of interpretation, moral standards, conclusions from previous debates, and so forth.

In processes of policy making different views on how issues should be addressed compete for supremacy. Common for theories on policy processes is to assume that individuals and groups, usually referred to as actors, interact on the basis of different views and convictions, with a policy plan as a possible result. Problems and solutions (or elements of both) are tied to specific actors. Actors as well as problems and solutions compete for recognition in policy plans. Such policy plans, built on concepts, facts, opinions, and other memes, always contain plans to change (an) organization. No matter how different actors think, eventually policy plans are produced, even if it should only be a 'steady as you go' policy. Therefore, the study of policy processes is a good area of knowledge to study questions on how memetic evolution works, and how it is to be described.

In this paper we first introduce the framework and its conceptual building blocks In the description of lineages a mechanism for variation production (weaseling) is introduced, along with social mechanisms which can prevent this (concept-locking mechanisms).

A case study at a Dutch University is continuously used to illustrate the framework. In this case study the question is raised as to what the 'democratic qualities of the administration of the university' are. The following conclusions argue that the view established by the framework is both an elaboration on current policy theory and a connection between biological theories and theories on public policy. After the references a list of definitions is presented.

2. The Framework

2.1 The institutional system and the case study

In this paper we will refer to the case study 'University of Nijmegen', or KUN (after the Dutch name 'Katholieke Universiteit Nijmegen') to illustrate the framework.

After three years of debate the University of Nijmegen in the Netherlands carried through (in 1993) a major change in its regulations. The regulations were changed to what members in the University Council regarded as being 'less democratic'. The University Executive Board, however, saw this change as an important and necessary step forward to the future where 'the competition will become more difficult'.

This three-year-debate included over 80 documents which we used as data. In the end it resulted in three changes in the regulations. Two major policy proposals were put forward, but only a few of the points in these proposals were finally included in the regulations.

The policy making process at the University of Nijmegen, and in fact all such processes, do not take place in a void, but in an administrative structure which can be described by means of institutions. Institutions are rules stipulating which specific actors have the power to make decisions, to write down policy proposals, and to influence for instance decision makers with their knowledge of, or power elsewhere in the organization, etc.

These rules can be laid down in laws and regulations. Nevertheless, such rules are often only part of the organizational culture: they are not written down at all.

Policy plans are formulated and approved of in such an institutional system. The institutions determine where some of the conceptual building blocks of the framework are situated in a policy-making process. Therefore we will briefly go into the institutional structure of the University of Nijmegen.

We will restrict ourselves to examples concerned with the central institutional structure relevant to the changes in the university regulations (in Dutch 'structuurreglement') made in 1993. The University of Nijmegen has three central organs: the 'KUN Foundation', the University Executive Board and the University Council (from now on referred to as Foundation, Board and Council). The Foundation is the legal owner of the land and buildings, appoints the members of the Board, and can set new regulations. The members of the Foundation are appointed by the convention of bishops of the province of the Dutch Roman Catholic Church. The Board is appointed by the Foundation, except for the Rector who is appointed by the Council of Deans (chairmen of faculty² boards). The Council is elected by and from students and personnel. Members of the Board are not appointed without 'hearing' the Council and the other members of the Board. Before changing the 'structure regulations'³ (from now on referred to as 'regulations') the Foundation must 'hear' the Board and Council. We will expand on the history of the democratic institutions of Dutch universities later on in section 2.5.

The institutional system so far had to do with formal written rules. A good example of cultural rules was the behaviour of the Foundation. It did not impose new regulations, but left it to the Board and Council to make the decision to change the regulations if necessary, and if so, to formulate a proposal. After the Foundation posed the first questions whether and how the regulations should be changed, the Board and Council needed three years to formulate a proposal that gained support from both.

Besides the decision makers, there were also other relevant actors: for instance one of the two major policy proposals was formulated by a committee appointed by the Board, the other one was formulated by the civil servants of the 'Bureau of the University'.

2.2 Concepts for policy making

In institutional systems, as described for our case study above, policy plans are formulated from time to time. To consistently describe this process, we have need to introduce a number of concepts. These are memes, replication and retention systems; interaction, arenas and their selective environment; and lineages.

Policy making always takes place in (a group of) arenas where it is decided what memes (ideas, actions and such) end in a policy plan. In these arenas ideas come and go and compete for a place in the minds of people and, in the end, for a place in the policy plan. We will now describe the concepts more precisely.

2.3 Memes, replication and retention systems

The 'meme' is one of the most central concepts in evolutionary policy processes. It is defined as a replicator: 'a piece of data that is copied from individual to individual without too much alteration' (However, we will argue in the next section that a meme can also be an interactor.) In an evolutionary framework a meme is a replicator, a term that was first used for genes (Dawkins, 1976) [8].

In human cognitive processes it is quite common that ideas, normative criteria and other entities are copied from individual to individual. When we hear an argument why a specification should be taken, we might remember it and repeat it to others, or incorporate it in a proposal for a policy plan. Ideas thus transmitted from individual to individual, or from report to report, are called replicators. The acts in which this transmission takes place are called replications. A replicator contains data or, in other words, has a 'coded structure' which stands for something else. Such replicators are called 'memes' when the replication system is the brain⁴. Memes may be ideas, but also ways of thought, complete models of how (parts of) our world works (theories), examples or metaphors to explain things, and so on. Just as genes, memes are replicators, be it in a very different replication environment and process. Likewise, memes may contain data which becomes information when interpreted by an interpretation environment. While the interpretation system of genes is always of the same kind (Ribosomes and so on), interpretation systems of memes usually differ ('democracy' may mean different things to different people and in different contexts).

When replicators are not replicated, they are stored in retention systems or memory. As to genes this is almost always cellular DNA, but memes can be stored in many kinds of retention systems. Books, brains, tapes, and computer memories are possible meme storages.

In the case of the University of Nijmegen several 'new' memes could be identified. They first surfaced in the second proposal for the policy plan written by the committee 'Zeevalking' (Second report Commissie Zeevalking, 1991) [6]. The committee was appointed by the Board while Zeevalking was the name of the chairman of the committee. In this report external factors are described which 'have an influence on the university'. Examples of these factors are: competitiveness and decreasing government funds (page 4 and 5). These memes, as reasons to legitimize a change in structure, were replicated without too much alteration to other actors (Foundation and Board), and were still evoked at the end of the discussion by these actors. These factors and their description were no original ideas but, partly but literally, copied from another document (Van der Zwan, 1990) [33]. The last mentioned document was the result of a conference held in December 1990 by the Ministry of Education, on the same subject. In fact this conference was one of the reasons for the Foundation to ask the Board whether a change in the regulations was necessary.

This is an example of replication. A part of one document is copied to later documents and, in this case, to another institutional domain: arguments from a national discussion were copied into a discussion on policy making for a particular 'private' university. The link between these two different discussions was fairly obvious since the national document was distributed among the members of the Council at the Council meeting in January 1991. Furthermore, important organizing concepts from the document, such as 'integral management', were part of the official assignment to the committee. These organizing concepts also replicated successfully via the field of actors, as well as over time (they were mentioned throughout the whole process).

2.4 Selective interaction and arenas

Selective interaction, or 's-interaction'⁵, is the second central concept next to replication. S-interaction processes result by definition in a direct or indirect weeding out of replicators. This always takes place in arenas. Therefore, arenas are defined as the place where s-interaction takes place at a certain moment in time. Arenas can be prescribed by the institutional system. However, different assemblies at different stages in the same kind of arena produce different s-interaction events. At these different events a different composition of the arena is probable: not all members will be present at all times. Especially if the collective actors in the arena consist of many members.

S-interaction can be illustrated by a particular difference of opinion between the Council and the Board of the University of Nijmegen. This s-interaction took place between the Council and the Board at several assemblies of the Council where the presence of the Board is required. The Board and Council had agreed to implement what they referred to as 'integral management', without damaging the 'democratic quality of the administrative structure'. However, this agreement came down to nothing when it became clear what each of the actors meant by these concepts. Firstly, the Board interpreted 'integral management' as the integration of 'policy and control' (in Dutch: 'bestuur and beheer'). In the past there had been a separation between the

management of buildings, personnel and such like matters (control), and the management of the content of research and education (policy). This separation was particularly recognizable at the departmental or faculty⁶ level, where a director was in charge of 'control', and a board and council were in charge of 'policy'. The Board, however, not only wanted to put Faculty Boards in charge of both of these management tasks but, secondly, also wanted to restrain the authority of the Faculty Council. They proposed to abolish the right of amendment and initiative, the authority to decide on the budget, and so on. In addition they proposed to do the same at university level. The authorities of councils to decide on matters, would be brought back to the right to 'agree', together with the possibility to appeal against decisions of boards they would disagree with.

The Council was furious. They had agreed with 'integral management', meaning only to integrate the management of 'control' and 'policy' at faculty level, but they had certainly not agreed with any decrease of authorities of any council. The members of the Council felt that the board had distorted the agreement to a high degree. Besides the different opinions about the concept of 'integral management', it also meant a difference of opinion on what 'democratic' implies. The Board apparently argued that restricting the rights of the council to a right to agree did not damage the democratic qualities of the administrative structure; whereas the Council argued that the 'right of amendment and initiative' were 'fundamental' to any democratic administration.

In the end, the Board reached a compromise with the Council. The right to agree was taken up in the regulations, but not exactly as meant by the board. The right of amendment was ingeniously added so that the Council could add and change elements of proposals made by the Board before deciding whether to agree to a proposal as a whole. The Board in its turn could declare a particular addition 'inadmissible' in which case the Council decides whether to agree to the proposal if not containing the addition. This construction was claimed to be an existent one, and thus a replicated meme, and referred to as the 'vote blocque' construction. Furthermore, the Board still had to justify its actions to the Council, to which it opposed strongly. The Council lost its right of initiative, and was granted the right to advise.

In this example memes compete for a place in a policy plan. The memes that compete are the descriptions of authorities of boards and councils. However, these memes are not only replicated, but they are also in competition or, to put it differently, in s-interaction. The impossibility of both proposals (the right of amendment and initiative versus the right to agree) ending in the regulations, makes this event an s-interaction process where competition takes place: the right of initiative was weeded out. The right to agree and the right of amendment were not weeded out, since a new article was introduced to combine these rights. The right of amendment did change of course, because an amendment could be declared 'inadmissible'. The mechanism by which the competition took place was negotiation, where both sides handed in some points of view to come to an agreement.

Although memes can be weeded out by selection because they are subject of discussion and negotiation, many memes are not. Analogical to neutral mutations and 'spandrels' (Gould, 1997) [11] in biological genetic evolution, many memes in s-interaction processes are weeded out by coincidence. Most memes are never discussed, but simply make it into approved proposals

because they are linked to memes that are discussed and selected for. They are not selected for, but there is (positive) selection of them.

When a meme (a structural entity) is not replicated but in the process of s-interaction, we will call it an interactor, corresponding with the definitions of interactor and replicator by Hull (1980; 1982; 1988a; b; see also Speel, 1996b) [14].

Memes can thus be both interactors and replicators. The name they are given depends on the process they are in at a particular moment in time. So the concepts of replication and s-interaction are definitions of process. Memes are the basic structural entities. When they are replicated or stored they are replicators. When they are in s-interaction, the same structural entity, or a translated form of it, is an interactor. A definition of process can easily be understood by taking a chair as an example. When you sit on it, it can be defined as a piece of furniture. When you hit someone with it, it is more appropriately defined as a weapon. A meme like "bald is beautiful" might be transmitted from a bald man to a man with a lavishly head of hair. In this transmission the meme is a replicator. But when the man with the beautiful hair thinks about it, he might really disagree. In the act of judging the meme as untrue, the meme is an interactor.

While this standpoint may seem strange, we believe it to be well founded in the debate on species as individuals (see Ruse (1989) [24] for a series of papers relevant to this topic). Therefore, ignoring it will generate serious philosophic problems with the foundations of evolutionary theory.

These definitions of process are derived from biological evolutionary theory. There genes are replicators, which are translated into interactors such as enzymes, organisms and so forth (Brandon, 1988) [1]. The implications of this classification cannot be dealt with here, but are fundamental⁷ to the difference between 'Lamarckian' and 'Darwinian' evolution. S-interaction processes take place in arenas at a certain point in time. An arena can be the mind of an individual, but also the minds in collective or group decision processes, that is where people debate on the adoption of methods⁸. In the example of the University of Nijmegen the arena was the assembly of the Council. We speak of an 'internal' arena when s-interaction takes place in one individual. When s-interaction involves more people we speak of an 'external' arena. Accordingly we can speak of internal and external s-interaction. An internal retention system refers to (parts of) a brain and an external retention system is any retention system outside the brain, i.e. books, tapes and so on.

Summarizing the definitions of central concepts we end up with:

An arena is a place where s-interaction takes place (at a certain time) according to certain rules (institutions).

An interactor is an entity that 'interacts in an arena where this action results in the weeding out of a replicator in a retention system'.

A retention system is 'a kind of memory where replicators are stored'.

In the struggle for survival of description of authorities in our case study mentioned above, the external retention system was a single policy plan, but the decision processes took place in multiple external arenas.

We may add that arenas are always coupled to retention systems: arenas serve as a kind of filter as to what memes get into their accompanying retention system. This is shown by the above-mentioned example. The decision to choose for either the right to agree or the right of amendment and initiative was eventually taken in an external arena. The retention system the surviving meme was added to was 'the regulations'.

2.5 The selective environment and levels of retention

S-interaction in an arena results in the weeding out of memes. This weeding out can take place on the basis of different kinds of 'criteria'. The sum of the factors being decisive on what memes are weeded out is called the 'selective environment'. The selective environment is what causes weeding out (Brandon, 1988) [1].

The selective environment may consist of more or less formal criteria to weigh options. It might be decided that the authorities of councils should remain the same because 'changing them will decrease the democratic quality of the structure', where the criterion is, of course, 'keeping the democratic quality the same'. Dunn (1993) [10] describes a classification of different criteria people use in policy processes.

The selective environment may also be based on other kinds of factors, for instance the relative powers of decision makers. If a decision maker can decide what he wants, without taking into account the opinions of others, his power will suffice for the decisions to be taken. The Foundation, for example, has the power to set and change the regulations of the University of Nijmegen without taking into account the opinions of Board and Council. The memes endorsed by the Foundation would thus win without contestation on content. Of course there are supplementary causes to this explanation. While the Foundation might do what it wanted without listening to Council and Board, we would still need to explain why it made decisions in the specific way it did. It may be possible that memetic s-interaction has taken place somewhere in the Foundation as well.

Memes that, through selection processes in arenas, make it into retention systems, may have a different status. A meme in a policy plan can, for instance, describe an action to be taken, or just be a description of something that needs to be changed. The policy plan (regulations) finally set in our example of the University of Nijmegen, included the decision to implement 'integral management', intending to be a compromise between that of the Council and that of the Board. But the decision to change the regulations also included arguments explaining why a change was needed. The decision implies memes referring to actions to be taken, whereas the other memes were just a part of the arguments to rationalize the change. The status of both kinds of memes is clearly different. We will refer to this difference in status as the levels of retention.

We distinguish four levels, to be referred to a 'levels of retention', in the 'status' a meme can have in a retention system:

- to have knowledge of a meme;
- to judge a meme to be relevant for a discussion;
- to endorse a meme; and
- to translate a meme into action.

An actor may have knowledge of a meme. One of the proposed policy actions can be to 'abolish authorities of boards'. However, a member of a council who thinks that decisions get better if councils can amend them, may think this not to be a good idea. He may fear that decisions will be taken which turn out to be unworkable. Therefore he may judge it to be unwanted, and talk to his fellow council members, explaining this to be a bad idea.

Another council member may hear of the proposed action, but may judge it favourably. He then knows the meme, thinks it to be relevant for the discussion, and endorses it. He will probably also defend it when the truth or usefulness of the meme is doubted by others.

The fourth level is a more special level, since not all memes can be translated into action. Only prescriptive memes can be translated into action. When an individual endorses a meme that is a prescription he will act on it. Religions hold prescriptive memes of course, but so do policy plans. However, in policy plans it is usually the case that the individuals that have to execute the memes (policy implementation) are not the same as those who have the competence to approve on it.

The first three retention levels can be applied to memes in all retention systems. The fourth retention level is a special case.

A failure to differentiate in different levels of retention leads to confusion. Especially since more levels are already being used in the memetic literature. Dawkins (1976) [8], when referring to religions as meme complexes, uses endorsement and applications of religious rules and beliefs as success criteria. Best (1997) [2], for instance uses replicative success (level one and two) as success criteria. Vaneechoutte (1993) [29] uses replicative success in the phrase 'successfully distributed - horizontally - into different brains', in the context of religions as meme complexes.

A failure to differentiate in different levels of retention can also obscure important insights. Many memes are very successful in spreading, exactly because they are not endorsed. There are, for instance, many discussions and papers about Lamarckian mechanisms in genetic evolution. In many discussions this meme is referred to in order to state the point that Lamarckian genetic evolution does not take place. The Weismannian barrier is often used to state the same point as well. Papers and books mention Lamarckian evolution with regard to the history of the field of biological evolutionary theory. However, in the context of cultural or memetic evolution Lamarckian evolution is mentioned to emphasise the difference between genetic and memetic evolution, and it is endorsed that cultural evolution is Lamarckian (see Gould, 1997) [11]. Taken together, Lamarckian evolution is a successful meme, but the factors for its success are mixed, involving endorsement and relevance to a discussion (because it is wrong) as the levels of retention.

In memetic theory a successful meme is often taken to be a meme that is 'true' (Darwinian theories are more successful than Lamarckian theories in genetic evolution) or useful, to others with what spreads well. Needless to say that these two different criteria for success will yield very different results in memetic analysis, both for the dynamics, the mechanisms, and the selective forces involved. It is probable that memes that spread because they are not true, or offensive for instance, spread because they evoke a reaction from people opposed to the message in the memes. These people will replicate the meme while stating it is untrue or offensive. Calling someone a 'Nazi' for instance on the internet will replicate that meme, but the emotional mechanisms involved will be different from when you argue that it is a shame that Princess Diana has deceased.

Diagram 1 shows a stylized outline of the framework where two collective actors interact in a policy-making process. Human H1 and H2 form one actor, and H3 and H4 the other one. In this process an old policy plan (D1 for document 1) is changed into a new one (D2). The memes in the documents are replicated to the internal retention systems. The lines stand for replication. Before external retention systems are produced (documents), s-interaction in arenas takes place, with its selective environments.

Diagram 1. A stylized representation of the framework. This diagram shows an imaginary case, with arenas, retention systems, actors and a lineage. Time runs from left to right.

The diagram is but a model of reality and, for the sake of clarity, not all details were depicted. For instance internal arenas can always be present with all humans in the diagram. Only the first arena on the left upper side is an internal arena and should be in the human. The second arena left below is an external arena. Also there are only single lines from humans to arenas. There could be a lot more lines, if the depicted external s-interaction is accompanied with internal s-interaction in the humans' internal arenas⁵. The third arena, in the upper middle, is followed by the last one without showing intermediate human replication. If the diagram should be exact, it would show humans after every external arena, since humans replicate memes.

D2 stands for documents and other memes that are used, and which come from outside the organization. In the middle, two propositional documents are produced by actors consisting of H1 and H2 (say the board), and H2 and H3, (say a council). Collective actors reconsider their endorsed memes after reading each other's documents and in the final arena the final policy plan D5 is agreed upon. The line going from D1 to H3, D4, H2, D5 is an example of a lineage that runs through the process.

2.6 Lineage

In this framework we recognize lineages of memes (the line in diagram 1 going from the first to the last document). A lineage is a logical result of the concept replicator. Genes and memes, or in general replicators, are repeatedly copied and thereby, over time, form a lineage. A lineage is thus a line of replicators connected by heritage, i.e. a (changing) historical entity. In the framework lineages 'linger' through retention systems by replication, possibly changing.

Replicators in lineages can change or mutate in many ways in memetic or conceptual evolution, yielding variation (see Price (1995) [23] for a possible mechanism). Hull (1988a) [16], for instance, refers to 'weasel words' as words that change in meaning, whereas the actual word remains the same. To put it more precisely, the change in meaning takes place in a lineage, so we will refer to this as a weasel lineage. The discipline that studies such changes is called etymology. Take, for example, a word that is replicated inside a mind. Technically this is not a lineage, since memes are replicated from individual to individual. Therefore we shall call such a lineage an 'internal lineage'.

Suppose an individual hears of the word 'democracy'. He might take up this meme from others, with the explanation that it means 'voting for a parliament, which then takes decisions'. Suppose the parliament in the example he heard were a national parliament. We can call the description with the example of a national parliament the 'context' of the word, which gives the word its meaning. Suppose this individual then contacts a Dutch University and its administration in 1996. Here, there is then another kind of democracy, where an elected council takes decisions. The people involved tend to call this also democratic. The person then connects the word democracy he already knew from the national parliament to the new context of the council in the university. On top of that he might learn that the council, once elected, can ignore the opinions of the voters and that its behaviour, and therefore the council itself, is called 'undemocratic'. This situation is illustrated in diagram 2.

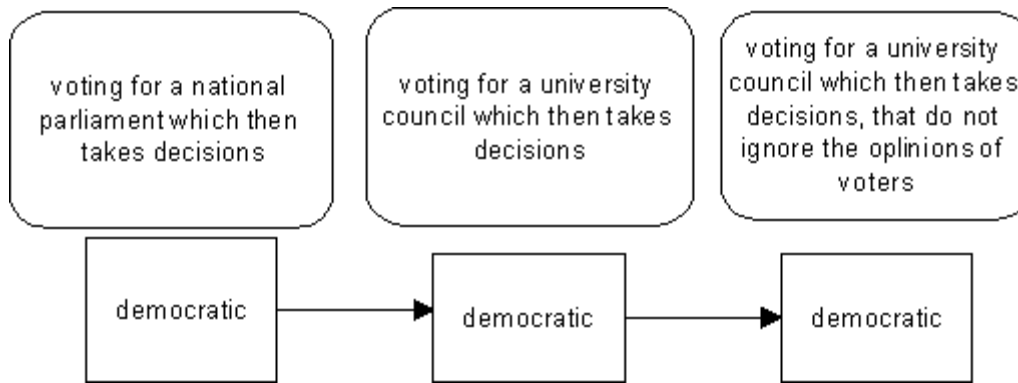

Diagram 2. A stylized representation of the weasel lineage 'democracy' that changes in meaning.

What we see here is an internal (in one brain, or mind of an individual) memetic lineage that has changed over time by influences from outside. The meaning changed owing to connecting new contexts to the same word. In biology we would say that the lineage has mutated. In this example, democracy is thus a 'weasel lineage'. If the change in meaning means that little of the original meaning resides (according to some standard), we can either say that the lineage has split or that it has ended. In the first approach the word democracy is regarded as a lineage that remains the same, but the meaning attached to it changes; it is linked with different other lineages of concepts. In the second approach the word democracy and its meaning are regarded as one meme, and the change equals a mutation or new variation: a new meme is born.

This weaseling is even more likely to happen when memes are replicated from individual to individual. When the word 'democracy' is replicated from a member of a national parliament to a member of a university council, it is bound to change in meaning. The individual, who takes up the meme, will attach his own meaning to the word, depending on what he uses it for, and what he already knows about it. Memes that are thus replicated will often change in meaning. However, together with a meme, its interpretation can be replicated simultaneously. So by communication on the meaning of a meme, individuals can 'level' their interpretations.

While it is shown that a meme can have a very different meaning for different individuals, it still counts as the same meme as long as it is replicated directly. The change in meaning is irrelevant to the definition of what counts as a meme. The only decisive criterion for a meme in the same lineage is heritage.

In the case of the University of Nijmegen such 'weaseling' can also be recognized. The Board in one of the proposals for a policy plan calls the 'structure' of administration democratic when there is 'a structured influence from representatives of the university community on the administration'. The Council interpreted a democratic structure as a structure in which the council has the 'right to submit amendments and propositions together with the right to decide on the budget'. This example shows that the same concept meant quite different things for different actors.

Once you think about it, it turns out that almost all words we use which are conceptual (whereas words like 'the' or 'it' are quite stable), and which have meanings in the sense mentioned above 'weasel about' quite a lot. In fact, when such weaseling is not wanted, it takes specific precautions to prevent its happening.

There are several stabilizing mechanisms in social processes to avoid weaseling of words or concepts. In science there are formal theories characterized by formal, and thus fixed, definitions.

In law there is jurisprudence which fixes the meanings of concepts by means of frequent interpretation of examples in cases. Jurisprudence acts as a 'lock' on definitions. Once a concept has been given a specific meaning by a judge, or court, other courts and judges are required to use the same interpretation. If courts come into conflict a higher court must resolve this and re-establish a uniform interpretation. We will refer to the stabilization of meaning as 'locking' a concept (or meme).

While weasel lineages are important for the creativity of language, they make a clear understanding in communication impossible where people need to concentrate on what they actually and precisely mean. In policy making this is of course very important, if we do not want to end up in endless misunderstanding.

Actors in policy situations that who to do something different from what they have agreed upon, can become very inventive with weaseling. In negotiation it is a common feature to make agreements which can be interpreted (connected to meaning) in many different ways, so that all partners in communication can agree. It is for instance an open question if the Board and Council would have agreed on 'democratic' and 'integral management' as starting points for a policy change if they could have foreseen that they would disagree later on the meaning of the words.

The examples of 'democratic' as an internal lineage and as a subject of debate and confusion within the debates at the University of Nijmegen is also relevant to the evolution of the 'democratic' institutions in Dutch universities in the past forty years. Before 1960 Dutch universities were governed by the Ministry of Education and by their own internal structures.

The internal structure was dualistic in that the university was governed by a Board of Governors (in Dutch: 'College van Curatoren'), but academic policy matters were decided upon by academics: Chairs (professors) at the basic level, the Faculty as intermediary and the Senate at the central level. The Faculty as well as the Senate were formed by all professors involved. In an act, seen as the first modern regulation of the Dutch universities in 1960, the University Education Act ('Wet op het Wetenschappelijk Onderwijs'; W.W.O), universities were given more autonomy (they were given an autonomous legal status), and the competencies of the Faculty were increased as opposed to the competences of Chairs. The Faculty became responsible for the coordination of exams and education. The universities were also financed differently in that they were no longer funded on the basis of expense account, but on the basis of centrally allocated budgets based on information given by the universities and connected to a formal planning system. The Chairs, however, were still appointed by the national government, thus limiting the autonomy of the universities. The special universities, such as the University of Nijmegen

mentioned above, were also included in the allocation of money, be it that they were only given 95 percent compared to state universities until 1970.

The basis of the 'democratic' institutions was first laid down in 1970 in the act 'Wet Universitaire Bestuurshervorming' (WUB; University Government Reform Act). It included the Council structure and also a list of explicit goals including 'democracy' at universities. This law was passed as a result of student and academic protest against a national policy plan, formulated because the university structure could not handle the growth of the universities in the sixties. The policy plan proposed a Presidium of three individuals having not only the competences formerly held by the governors, but also the academic. The plan catalyzed a strong protest movement in the opposite direction of the concentration of competences toward democratic structures.

The WUB was passed as an act in 1970 and would eventually last fourteen years, until 1984 (These data are based on Groot; 1988) [13]. The democratic structures, however, lasted until recently: in 1996 the 'Modernisation University Governmental Organisation Act' was passed ('Modernisering Universitaire Bestuursorganisatie' (MUB)) which reduces and changes the influence of councils.

A memetic empirical question here is where the 'democratic' memes in the WUB came from. Some say they were derived from the Dutch laws on the government of municipalities, but others deny this. This question might be answered by a study on who actually wrote the proposals for the WUB and what sources he or she used. Another more objective method would be to analyze the WUB, and proposals that preceded it, on specific word phrases to see if they fit words phrases in the law on municipalities.

However, it is obvious that since the WUB was introduced in 1970 the democratic memes (as well as their formal interpretations resulting in regulations of individual Dutch universities) have been around in the formal body of law in the Netherlands, and that they can be regarded as one lineage or perhaps a network of lineages.

It may be nice to observe that the University of Nijmegen was experimenting with democratic structures before the WUB was passed as an act, and that the changes in the regulations described above were also prior to the MUB. Since special universities in the Netherlands were allowed to have different regulations (and state universities were not, although this has changed somewhat since the MUB), they can change their regulations based on their own interpretations and goals. In other words locking mechanism of legal memes that have been present for state university regulations (they were to be approved of by the minister) were not operating as vigorously on the regulations of special universities. The results of both policy processes, the national one and the one at the University of Nijmegen, are also quite different. The board of the University of Nijmegen however, is already planning to change the regulations again toward the present situation in state universities.

So far we have been talking about conceptual lineages. However, to be complete we must mention that Hull (1988a) [16] discerns two kinds of lineages: social and conceptual ones. Conceptual-, or meme lineages are lineages of ideas, theories and the like as we have explained above.

A social lineage is a group of people that can lose and gain members, that has the same name or is bound together by a common interest, task, and etcetera. Social lineages are for instance actors in policy and in political theories. They are called lineages because they are bound together by a historical line that can be traced. While the membership of such a group does change, and possibly also the name and/or the ideology, we still see such groups as one and the same. Thus their identity is essentially based on historical lines.

Before completing this part of the paper, in order to avoid confusion, we need to mention that 'lineage' in biology can have two meanings. First of all 'lineage' may mean a replicated line of genes. In this case a gene stands for a complex of pieces of DNA that code for one protein which, in such a lineage, may change by mutation, including recombination.

The other meaning is that of a species (or a sexually reproducing 'lineage') which can also be called a lineage or a 'whole' that changes genetically over time. It is this type of lineage that is commonly said to evolve by natural selection. While a lineage of genes may mutate, a species as 'lineage' can adapt. In this paper we will refer only to the first meaning of the word lineage. The second meaning for systems that can adapt or learn should be referred to as a 'selective retention system' (Campbell, 1974) [5] or perhaps an evolver⁹.

3. Implications of the Framework

The framework has implications for a) public policy theory and b) memetic theory.

3.1 Implications for public policy theory

There are five main implications for public policy theory.

Firstly, the framework describes the cognitive side of policy making according to the modern evolutionary paradigm. Therefore it can be used to 'translate' understandings from different disciplines of science that were separated before. The understanding acquired in different disciplines is more readily usable and this can yield new theoretical combinations. More specifically, the elaborated 'toolkit' of modern evolutionary concepts in biology can now be used in disciplines where it was not used before. This toolkit has many benefits, among which the dynamic characteristics, in contrast to, for instance, the approach currently used in institutional economics (Williamson, 1985) [32]. Furthermore it can describe well variation production or, to put it differently, innovations (which has enriched economic theory as well), and brings along population thought as an elaboration to platonic essentialism¹⁰.

Secondly, the framework focuses on cognitive processes in policy making. Many policy theories describe policy making as being mainly a political process, where actors interact to increase or keep their power or income, and to defend their ideology or points of view. Such theories refer to the political or power-driven rationality (often only to be established after actions have been taken) by which actions of actors can be described.

This framework can be used to emphasise that the cognitive processes by which choices are made are not only driven by political factors, but also by the development of the understanding

of the content of problems and solutions. Where many policy theories do acknowledge that this understanding is a factor, they do not have a model to describe how it develops. However, if we want policy processes to result in the solutions of problems, this understanding is crucial. In other words, the framework focuses on interpretative institutions, where most policy theories focus on interactive institutions (Campbell, 1995) [4]. Interactive institutions are about the interactive behaviour of actors with regard to the political power. Interpretative institutions are about the models with which problems, solutions and so on are described. So our framework can serve as an elaboration on theories on political interaction between actors.

Thirdly, rational, non-rational and other factors in selective environments can be viewed together in one framework. In the real social world both emotional factors and rational deliberations on what to do play a role. Emotional factors include group identity, non-rational preferences of individuals for specific actions over others. Furthermore, factors as the 'catchiness' of concepts, persuasion caused by an intimidating personality of an individual, for instance, and so on may play a role. From the specific memetic side of theory we can add that meme complexes may have become adapted to be endorsed and dispersed successfully, resulting in memes that are hard to resist.

Some actions can simply be popular at a time, while nobody can exactly tell why they should be taken. Some actions might be adopted because respected people say they should be taken, or because they are brought forward in a persuasive manner. Lynch (1996) [19] gives the example of memes that are selectively replicated among different social classes in society. Fashionable memes in a 'higher' class are often resistant to memes in lower classes. It may be that actors (or individuals) who see themselves as members of a higher class will resist memes that are proposed by actors in a lower class. This can be generalized by saying that members of a group with some identity might resist memes coming from other groups. Famous examples of course can be found in struggles between employers and employees, or between memes of environmental activists and entrepreneurs. Some actions that entrepreneurs can take to improve the environment are good for profit as well. Still such actions can be resisted, simply because they are proposed by environmental activists. Of course the same kind of processes play a part in policy making elsewhere, including public policy.

The concept of the selective environment enables us to group these factors into one concept. This may seem trivial, but many disciplines only consider either rational or non-rational factors without integrating them. In policy sciences rational deliberation is often seen as the basic explanation for decisions.

Fourthly, through the concept of lineage, the framework implies a (specific) historical view on deliberation. The models used to describe problems and solutions are historical entities, either made up when needed (new variation) or copied from already existing memetic sources. This puts the view that organizations are under the rational control of humans even more in perspective than the concept of 'bounded rationality' implies.

In a policy process descriptions of problems and solutions or, in other words, goals and actions can be copied from other institutional systems or from previous discussions in the same institutional system. For instance, the description of the problems of the University of Nijmegen

were copied from the national discussion on changes needed for public universities: a different institutional system. Another possibility is that descriptions are already available from past discussions in the same institutional system. When descriptions of problems and solutions, or conclusions from discussions (s-interaction) from the past are copied without deliberation whether they are correct, we might speak of 'conditioned', or rule based decision making. Memes from the past are copied when current events seem similar to previous events, or events experienced in other institutional systems. Thus the similarity of events leads to the appliance of previously developed memes.

As an example of theories that do not account for the cognitive development of concepts and models, we might refer to 'bounded rationality'. The concept 'bounded rationality', or satisficing behaviour, has become accepted when referring to decision-making. This concept implies that the selective environment for a decision (the problem to be solved) is already clear, but that there is a limit to the time and effort people will spent in finding the solution. Our memetic lineage concept elaborates on this in two ways:

The definition of the problem itself can be seen as part of, or the result of an s-interaction process. But more important is that the process by which solutions are searched for is also built on definitions, conclusions and concepts acquired in the past. These historically formed 'conceptual building blocks' are replicated in present time s-interaction processes. The descriptions of problems and solutions actually used, can be far from optimal. They may be ill-founded when conclusions reached in the past are incorrect. This may also include the complete frame in which problems and solutions are seen.

The search for the models in which problems and solutions can be described, as well as the application of such models in a new situation, takes time and effort. The restriction of the time and effort people are willing to invest ¹¹ in finding the right models, must be distinguished from the restricted effort to find solutions when the problems are already clear. Only this last restriction is what is referred to in 'bounded rationality' (Simon, 1976) [26].

Thus rationality is not only bounded by the effort to find solutions, it is also bounded by the abundance of seemingly fitting models, concepts and conclusions already available. When models are available that 'fit' the problems to a certain extent, it still takes effort to 'tinker' (in the sense of Jacob, 1977) [18] these, so that they fit a new situation. The 'tools' of deliberation are tinkered from old memes to possibly new and better fitting variations of these memes.

While we can use the concept of bounded rationality to account for the cost of finding solutions, bounded rationality will expand in meaning if we include the cost for the tinkering of models to view solutions and problems with, and the solutions and problems themselves. Furthermore, bounded rationality of course does not describe mutating memetic lineages.

Fifthly, the framework can describe lineages penetrating different policy organizations, policy themes and retention systems. This description makes explicit what everybody knows: people, and also policy actors, only create very few new descriptions, and solutions. They are often copied from what is already known elsewhere. The memetic view contributes to the study of how this happens and, for instance, why some solutions are so popular at certain times.

Once fashionable opinions and plans are recognized, it can be asked whether these fashions make any sense. Why do all universities in the Netherlands follow each other when changing their rules? To us, this epidemic characteristic of meme dissemination is particularly fascinating. The grouping of explanatory factors in the selective environment enables us to come up with hypotheses on what factors were important in specific processes. The possibilities we have sketched as factors are irrationality, rationality (political and with regard to the description of problems and solutions) and conditional decision making.

3.2 Implications for memetic theory

There are three main implications for memetic theory.

Firstly, if we view organizational processes in the memetic historical way as explained above, it becomes clear that even when organizations are managed and controlled by humans that behave with bounded rationality, their actions and deliberations are guided by already existing lineages of memes. The few choices bounded rational actors make, are thus partly under the control of memes already available. As Price (1995) [23] states: 'the organization can be seen as the product of the meme'.

This realization leads to the hypothesis that a considerable part of human memetic processes is replicative, as opposed to processes where deduction and deliberation yield new memetic variation. One can ask how much of human memetic evolution is replicative, and how much new memetic variation is involved? To investigate such a thesis we must, of course, first define what counts as new variation in practice.

In a policy context we can ask what processes and elements of institutional structures lead to more memetic variation? Price (1995) [23] for instance holds that a kind of isolation mechanism of meme complexes can yield new memetic variation. It would be a challenge to define and investigate such hypotheses.

Secondly, the issue whether memetic evolution is different from genetic evolution has generated some debate (see Gould, 1997 for instance) [11]. We agree with Hull (1982) [15] that many proposed differences are simply misunderstandings, among which the claims that memetic evolution is faster, Lamarckian or that only memetic evolution shows horizontal transmission of replicators. Instead we propose a new difference: Interpretation mechanisms in genetic evolution are almost always similar, contrasted by memetic interpretation mechanisms that almost always differ. This results in a different mechanism for variation production in memetic evolution: weaseling.

Finally, in examples used in memetic criteria, different levels of retention are used. We have argued that these levels should be distinguished properly to avoid confusion.

4. Conclusions

Memetic theory has been applied in the philosophy of science (Hull, 1988a) [16], in models of consciousness (Dennett, 1991) [9], or for describing religions (Dawkins, 1976) [8]. If these

applications have been useful, we have shown that memetic theory can also be usefully applied for policy science. Our framework describes policy-making processes as memetic selective processes, using definitions derived from modern evolutionary theory.

We have presented some observations that are elaborations on current memetic theory. We have shown that memetic lineages of conceptual words may appear to replicate without too much alteration, but that their interpretation can vary at the same time. The mechanisms and forces that produce this variation or weaseling are probably important forces in memetic evolution in public policy since special social 'locking' structures exist when such weaseling is unwanted. We have also shown that memetic evolution theory contains different levels of retention. Without these levels in success-criteria memetic analysis will be less explanatory.

Apart from these observations the framework contributes to theoretical innovation by connecting different fields of theory: policy theory and evolutionary biology.

Furthermore, we have argued that the framework contributes to policy theory in two ways. The use of the concept 'selective environment' makes the framework suitable to view rational, irrational and other factors as competitive or complementary explanations (selection forces) for decisions taken. A solution may simply have a good ring to it or be popular in a certain social group. It may be taken in a rush, or pass unnoticed because it is linked up with more controversial issues (in which case it is neutral). Most other theories presuppose only one of these forces to be relevant.

Realizing that many forces can play a part in decisions is, of course, an implicit criticism of the view that decisions are taken by rational deliberation only. It results in the view that human planning and anticipation can have very little influence on human organizing processes. Thus memetic evolution is less different from genetic evolution as may intuitively be assumed, since one of the differences between biological and memetic evolution is often taken to be anticipation and intentionality.

Acknowledgements

I am grateful to Jan Koolhaas, Tineke van der Ploeg, Inez Groothengel, Martin de Jong, Ronald Oosting and others for their help with the language and conceptual issues. Because I consider their help as an integral part of the conception of the framework I have used 'we' when referring to the author. Furthermore I thank the reviewers for their efforts which have improved this paper substantially.

Glossary

Actors:

Organs or agencies, individuals or groups which play a part in the policy-making process. Different parts are writing reports and interacting (including taking decisions).

Arena:

The place where interaction takes place at a certain time, possibly according to specific rules set by institutions.

Bounded rationality:

Actors are rational but their time, resources and knowledge to make and base decisions on is limited; so they stop deliberating on how to act at some point in time. Thus they are not perfectly rational. Actors that show bounded rationality are satisficing instead of optimizing. They stop searching for solutions when a solution they find or come up with meets their standards. They do not infinitely search for solutions comparing them in order to see what solutions are to be preferred (optimizing).

Conditional decision making:

(Also known as rule-based decision making (March, 1994) [20] the process of taking a certain decision, simply because it has been chosen in comparable situations in the past. The 'stimuli' of a certain problem leads to a reflex or routine of picking a certain predefined solution.

Institutions:

Rules according to which specific actors or individuals behave; in other words, stable patterns of behaviour.

Institutional system:

The rules of behaviour according to which actors act in arenas and by which some retention systems are defined. Formal and informal institutions include the definitions of some arenas and the part actors play there.

Interactor:

An entity that interacts in an arena, where this action results in differential perpetuation of memes into a retention system.

Internal lineage:

A lineage of memes which are replicated inside one mind.

Levels of retention:

The different status which memes in retention systems can have. Some imply actions that will be taken; others can be descriptions, arguments, and other memes.

Locking a concept (or meme):

The stabilization of meaning of a concept, or leveling the interpretation of it.

Lineage:

A line of replicators connected by heritage.

Memes:

Pieces of data that are a) copied from individual to individual without too much alteration, or B) that are interactors.

Policy making process:

- A process in which individuals, groups and/or actors interact on the basis of different views and convictions, with a policy plan as a result. Problems and solutions amongst other elements, often tied to specific actors, compete for recognition in policy plans. A policy plan can be a written document, containing plans to change (an) organization, or it can be an execution of changes made in a short period of time which are perceived to be related to one policy question or theme.

- A process in which an administration, or other actors and/or individuals think about, formulate, communicate and decide on plans to change things in society or in the organization itself.

Rational:

The use of deliberation or reasoning in making choices. As opposed to irrational choice (where affectionate and emotional factors are causes of decisions) and conditioned or rule based choice.

Replication:

The process where replicators are copied from one retention system to another.

Replicator:

A piece of data that is copied from retention system to retention system without too much alteration

Retention system:

A kind of memory where replicators are stored.

S-interaction:

the process that results in the weeding out of replicators, be it directly or not.

Internal s-interaction:

S-interaction where the arena is the mind of one individual.

External s-interaction:

S-interaction where the arena consists of more than one mind.

Selective Environment:

The sum of the factors, or in other words causes, decisive on what memes are weeded out in a selective event or in a number of selective events.

Selective retention system:

A system in which replicators, having coded for winning interactors that interacted on the basis of a common selective environment, are retained.

Weasel lineages:

Lineages which consist of replicated words that change in meaning, whereas the actual word remains the same.

Weismannian barrier:

The barrier between behaviour acquired in the lifetime of a biological organism and its genes. This barrier is referred to in order to show that the genes of an organism cannot take up such learned behavior. Genes and gene complexes only change by random variation and recombination. Natural selection takes care of deleting less 'fitting' variation, possibly resulting in adaptations.

Notes

Title

Parts of this paper were previously published in a slightly different form as Speel, H.C. (1997) A Memetic Framework for the Analysis of Policy Formation. In: European Institute for Advanced Studies in Management. Organizing in a Multivoiced World. Social construction, Innovation and Organizational Change. Leuven Belgium, June 4-6.

Note 1

Rationality, irrationality and bounded rationality are concepts that are accepted in public policy theories, but which have to be defined because they are used in many different ways. Rational here is used to refer to the use of deliberation or reasoning in making choices. Following Simon (1964) (25), choice is irrational when it is dominated by affective mechanisms such as emotions and instincts. Bounded rationality is used in the original meaning Simon (1974) (26) gave it: actors are rational but their time, resources and knowledge to make and base decisions on is limited, so they stop deliberating on what to do at some point in time. So this does not lead to perfectly rational based actions.

Note 2

Dutch universities consist of a central level and faculties. The faculties are the organizational parts where research and education actually take place. American universities often refer to this as 'divisions'. The word thus refers to a part of the organization, and not to what Americans understand by faculty: all personnel that teach or do research. These Dutch faculties (until 1997) always have a board and a council.

Note 3

The regulations of the University of Nijmegen are made up of three hierarchical levels of regulations: the articles of association, the structure regulations, and other regulations. These levels differ in the procedure by which they can be changed. The higher the regulation, the higher the actor needed to change it. In the case study the structural regulations were changed. In these regulations the administrative structure below the level of the Foundation is defined.

Note 4

To put it clearly, we would have to say that replicators are memes if their lineage has in the past been copied by brains. Here we assume that behavioural bodily patterns, also being memes, are also replicated by the brain.

Note 5

Hull (1980) (14) defines interaction as the process that results in the weeding out of replicators. However, in order to avoid confusion, we will refer to the same concept as selective interaction or s-interaction. Interaction in policy theory often means something like 'actors or individuals that take actions with regard to actions of others'. A policy scientist will call two individuals talking to each other interaction, while this is not what Hull is referring to when using interaction as a concept.

Note 6

See previous footnotes.

Note 7

The distinction between replicators and interactors is connected with the division of what Pattee (1977) (22) refers to as code and matter. Williams (1992) (31) speaks of the 'codical domain' when referring to code. Code can be replicated but, what's more important, can also be interpreted. The interpretation takes place by means of an interpretation system, and results in matter. The difference between matter and code is that code is in a 'rate-independent dynamical mode', whereas matter is in a 'rate-dependent dynamical mode'. In the example of DNA as code, rate-independence refers to the timelessness of the code. In transducing the code into matter, a time component is added, when the sequence of code is translated. Rate-dependent matter then has a form which interacts with other material in the cell where time is an important factor in the chemical processes of interaction. To code time is not important: the data are stored without time being an important factor to the code. The use of 'matter' here is, of course, no claim that code does not exist as matter as well. It simply states that the data in the code is not directly relevant to interaction processes. The data in the code becomes directly relevant to processes only after interpretation.

When a structural entity crosses this matter-code barrier, it is 'transduced' (Pattee, 1977) (22). In biology the interpretation system is the cell mechanism, which translates (while also transducing) specific parts of DNA at a certain time into enzymes. This theoretical theme is of course related to the genotype-phenotype distinction, since genotype is code (Calling phenotype only matter however would appear to leave behavioural parts of the phenotype out. However, it is clear that phenotype is no code.) Code has no meaning when separated from a translation system. Pattee (1977) (22) describes for instance that the biochemical mechanisms of the cell give DNA its meaning. The ability to discern between code and matter is for instance of importance to understand the Weismannian barrier. Without this barrier, the difference between 'Lamarckian' and 'Darwinian' evolution cannot be maintained.

In memetics we can also discern translations and transductions. They always take place in the brain. However, we do not have an accepted theory of how this takes place in the brain. For instance: are `thoughts' code or matter? Are memories in the long-term and short-term memory code or matter? I have no answer to this. Does the claim that a memetic Weismannian barrier in the brain does not play a part in memetic evolution mean that there is no barrier, or that it is crossed?

The inability to describe what things in the brain are replicators or interactors poses difficulties. For instance, I do not know how `thoughts' are connected to the material of the brain. This also means we don't know if interactors and replicators in the brain are separated as code and matter as they generally seem to be in genetic evolution. Replicators in biology are almost always code and interactors matter. But can interactors also be code, and are they in the brain? Calvin (1997) (3) refers to experiments on "RNA evolution" that do not involve a genotype-phenotype distinction. This implies that interactors can have codical characteristics while they function as matter.

We feel that in the end the part an entity plays in a process should be predominant in solving the question if an entity is a replicator or an interactor. This implies that some entities that are replicators can also be interactors (the RNA for instance). Interactors thus may have `codical' characteristics.

This may result in the conclusion that a memetic interactor in the brain has features of code. Whether this is correct remains unknown until we have a proven transduction theory for memes in the brain.

Whatever the problems with memes as code or matter, it is clear that memes in policy plans can be translated in two kinds of interpretation-steps by humans. First a meaning is attached to a meme (as in the weaseling described in this paper), and second this meaning can be one of the factors that causes specific behaviour of humans. In organizational and policy theories the relevant concept describing the translation of described actions into actual actions is implementation of policy. Some policies, such as laws, have well -organized interpretation systems, such as courts. Other policies are never transduced into actions at all.

Note 8

When a group of humans is debating, s-interaction takes simultaneously place in multiple arenas: in the mind of one or more individuals (internal arenas), and possibly also in an external arena. In such a case, the question arises whether the humans or memes, or both, are the interactors. In all cases memes are of course the replicators.

The question what entities should be called interactors in an internal arena is easily to be answered. Inside an internal arena memes are always the interactors. In an external arena the answer is more difficult. Do not individuals s-interact just as memes?

The answer is that individuals are most of the time the interactors. Only when multiple individuals (or groups that speak with one voice) make a choice on the basis of a common view and thus criterion, is it that memes are the interactors in the external arena.

When a choice is made on the basis of one or more shared criteria, all individuals communicating in the debate should come to the same conclusion. We can safely state this to be an exceptional event. This is only the fact when the criterion and the interacting memes are interpreted in one way by all individuals. This can probably only happen in environments where strong 'locks' on weaseling are executed. It is far more likely that individuals 'think' they agree on interpretations, but that in fact they all make different deliberations, and yet do agree with the outcome.

When actors do not agree on interpretations, other factors will influence the outcome. For instance, the power of one group over others.

If memetic criteria are decisive in a decision process, s-interaction does not only take place in the external arena, but also in the minds of the individuals involved. Memes in internal arenas are interacting simultaneously with memes in external arenas. While it appears that a group is deciding, individuals decide themselves too, and 'level' (communicate and agree with) their decision with each other. Of course it is possible that not all members do agree, and that in the mind of disagreeing members a different s-interaction will have taken place.

Note 9

Consistently with the definitions of our framework a selective retention system is 'a system in which replicators that have coded for winning interactors that interacted on the basis of a common selective environment, are retained'.

Our framework could be used to focus on selective retention systems (Campbell, 1974) (4). We have however chosen not to do so in this paper, although we plan to do so in the future. The approach of the framework as presented is thus a selective one.

In evolutionary theory we can discern selective theories (Cziko, 1996) (7) and theories describing evolution by selection or, in other words, 'learning by trial and error'. Systems that behave in such a way are called 'selective retention systems'.

Theories of competition between firms resulting for instance in a monopoly, are selective theories, just as the description of different species competing for niches in ecological theory, without including the generation of adaptations of these species. Evolution by selection-theories would of course include Darwin's evolution by natural selection, but also 'evolutionary learning' in economic theory as Vromen (1994) (30) mentions, or the 'trial and error learning' that Campbell (1974) (5) speaks of.

Note 10

Ernst Mayr (1982) (21) has pointed out that population thought is an important essence of Darwinian Theory. It is opposed to Platonic essentialism. In short this can be illustrated by

saying that essentialism describes entities according to their 'essence' for instance when we classify entities. For example describing a species in terms of characteristics can be called platonic. Darwinian Theory uses population thought which describes the difference in entities. A species would thus be described as having variation in a particular distribution. This is of course important because selection cannot be described without differences it can operate upon. The explanation of innovations thus needs population thought.

Note 11

Although we speak of 'are willing to', the choice of such models is often not consciously voluntary. People are often unaware of the models they use, and so have not chosen at all. They simply use the memes they are acquainted with.

EXPLAINING CULTURE: A NATURALISTIC APPROACH

By

Dan Sperber

Oxford: Blackwell, 1996

How to Catch Insanity from Your Kids (Among Others); or, *Histoire naturelle de l'infame*

I don't know how many of my learned and refined readers have ever had occasion to pass through Roswell, New Mexico, located as it is in an especially bleak part of what is, on balance, a rather ugly state. While it perhaps does not deserve an actual visit, Roswell is certainly worthy of contemplation: like Lourdes, it has become famous for something which never happened. I refer, of course, to the infamous myth that a flying saucer crashed there in 1947, making the national news, only to be covered up by the US military. A shrine to this myth exists in the form of the grandiloquently named "International UFO Museum and Research Center"; but more diffuse homage is rendered to it in nearly every shop-window, down to wedding outfitters. The inside of the museum displays limitless credulity in its exhibits ("What I have seen refuted three times is true"), with tasteless and incompetent art for decoration, the latter all the more painful for its self-evident sincerity. To the skeptical but casual eye, the museum is a mis-guided monument to a particularly absurd fanaticism, to the strength of human gullibility, to a race of barely-thinking forked radishes' capacity for self-delusion. Having taken it thus in with a glance, that eye dismisses Roswell and its Museum, and moves on (probably on Route 285) to more pleasant prospects.

That eye moves on; but the truly philosophical eye will linger. The child of the Enlightenment, trained to uncover the hidden springs of conduct, penetrates the inner workings of the museum with ease. It is housed in an abandoned movie theater, obtained from the city at nominal cost. The list of founding sponsors of the museum, displayed as a discreet plaque in the lobby, contains no names distinguished among the believers in UFOs, but instead various members of the local business elite (who, as experience teaches, are the real rulers of any American small town), and their banks. This plaque is flanked by equally discreet awards from the local chamber of commerce. In sum: the museum was created as a tourist trap by the local rulers, to their direct benefit. Its existence and character are admirably explained by that blend of precepts which Marx and Engels took from the English and French historians of society and distilled into "historical materialism." This brew now meets with almost universal approval among the learned and sensible, as we have earlier remarked.

However satisfactory this potion may be in explaining deliberate products of human effort, like the Roswell Museum, it does not seem to work so well with other cultural phenomena, like the story of the Roswell UFO crash itself. For how are people to know what, in view of their stations in society, it would be advantageous for them to believe, *and* believe it sincerely? Have we all little Marxometers, pointing us in the direction of our socially preferred beliefs, of whose existence we are unaware, even when the connection to our social condition is so recondit that its elucidation requires hundreds of abstruse pages under the imprimatur of Verso or the Presses Universitaires de France? Do Gramsci's "organic intellectuals" act as external Marxometers? None of these conjectures is satisfactory. Nor is the obvious alternative: Agent Mulder, in his

more (or, perhaps, less) paranoid moments, may suspect the UFO phenomenon in its entirety of being fabricated by the "military-industrial-entertainment-research complex," but this is neither a general explanation for wide-spread beliefs, nor one which a loyal member of the complex aforesaid, such as your humble reviewer, will adopt unless no other alternative presents itself. What is needed is a way of establish consensus, of getting the same belief into the minds of the multitude, without Hidden Persuaders actually implanting it there like so many buttock-dwelling microchips.

Now, it is a fact of observation that belief is catching. Here is a reasonably old recognition of this: in the 1764, the public prosecutor of Geneva ordered Voltaire's *Philosophical Dictionary* to be banned, condemning it as "contagious poison." I do not pretend this rather unimaginative civil servant had obtained a new insight into the nature of belief, or even had come upon a novel turn of phrase; I merely mean to show that this insight is an old one, and being no historian, nor even diligent, I merely pulled old books off my shelf until I found something to the purpose. The heart of the matter is that people have long realized that ideas can spread as though they were agents of disease and infection; in a word, like viruses, using that term in its original sense.

There is today a great and rapidly growing body of knowledge concerning the agents of physical infection, and the temptation to exapt that knowledge to the sphere of culture, to declare beliefs, traditions, practices and the rest of their kith and kin "viruses of the mind" is more than a biologist may be reasonably expected to resist. There are different vectors; there are opportunistic infections; there are parasites altering the behavior of their hosts; there are all manner of subtle and bizarre adaptations employed to get the viruses from mind to mind, from speaking in tongues to multi-level marketing to the axiomatic method. Best of all, we have the theoretical apparatus of Darwinian evolutionary theory, which fairly cries out to be put to use explaining culture as the result of the differential reproductive success of randomly varying replicators.

Again: this is by no means a recent idea. The first published attempt to explain social and cultural change in a selectionist, that is to say a genuinely Darwinian, manner, was made in an 1880 essay by William James. (This essay is also notable for its discussion of the equivalents of founder effects and genetic drift in small populations, and of the dismal state of American politics in the gilded age.) The idea has been re-discovered at intervals ever since then: late in the 19th century, for instance, by the French sociologist Gabriel de Tarde (to whom Sperber, in the book under review, attributes its first formulation), and by the German psychologist Richard Semon, both of whom, alas, burdened it with unfortunate pieces of metaphysical baggage, and were on the losing side of academic quarrels, which combined to put an end to the notion among humanists and social scientists. Since then it has mostly been the province of biologists, such as the great demographer and pioneer of mathematical biology Alfred Lotka and the molecular biologist Jacques Monod, with some honorable exceptions among the other inhabitants of the commonwealth of letters: the philosopher Karl Popper, the geographer André Siegfried, the historian and philosopher of science Stephen Toulmin. The great breakthrough, however, was in the middle of the 1970s, when one of the biologists, Richard Dawkins, had the genius to give the idea one of its most compelling presentations; and the further genius to give the replicators a simple but neologistic name, "memes," which sticks in the memory, forces explanations (that is, opportunities for infection) and so helps propagation. Since then, even literary critics have

grasped the notion --- at least, those literary critics who can actually understand popular science books.

This is all very fine stuff; it makes a great mind-toy and is a wonderful stick to beat over the heads of the infamous. The problem with it --- and I say this with real regret --- is that it's very far from clear that most of the elements of culture are stable replicators.

Here at last we come to the contribution of Sperber. Having completed the initiatory field-work proper to a cultural anthropologist, he returned to France to effect a synthesis of anthropological knowledge and cognitive science. One product of this effort was an excellent book he wrote with the linguist Deirdre Wilson, *Relevance*. This, depending on how it is approached, is variously an assault of the self-proclaimed science of semiotics, a new understanding of how we understand natural languages, a hypothesis on hypothesis formation, or an outline of a solution to the frame problem of artificial intelligence (this last has been aired in these pages before). Another product was the reluctant conclusion that most of what passes for explanation in anthropology is no more explanatory than the scribblings of a newspaper editorialist; like them, it is really either merely description, or interpretation, or sometimes vacuous. Genuine explanations of culture would show how its phenomena arise as the compounded effects of the myriad acts of individual people. Any methodological individualist would have agreed to such a formula; Sperber seems to have been the first to rise to the challenge it presents.

To explain how it comes about that every sapient creature in the United States knows the Roswell story, and similar facts, Sperber saw that we need an "epidemiology of beliefs," or even of "representations" in general. So far he has the agreement of the whole line of cultural Darwinists, from James to Dawkins to Aaron Lynch. Now, however, he reaps the fruit of his anthropological and cognitive studies. Unlike the genetic apparatus, the mind never leaves its contents alone; to think, even to remember, is to change. Nor are these changes, as it were, equally in all directions. Rather the mind works upon its representations in the direction of what Sperber and Wilson call "maximum relevance" --- roughly, extracting the most new information from them for the least processing. (This concept is made clear and precise in their book.) The correctness of their relevance theory is not essential to Sperber's present argument; it is enough that representations change in a highly non-random fashion. The changes undergone by stories in oral transmission, for example, have been studied by folklorists and psychologists at least since Bartlett's classical work in the 1920s, and the tendencies are both well-established and pronounced. The stories become more dramatic; more reasonable (according to the lights of the tellers); more stereotyped (according to the stereotypes of the tellers); etc. (These effects have appeared in these pages before --- in connection with the Roswell story, no less.) But these are all changes that make the story easier to remember, easier to retell, easier to accept and easier to relate to the rest of one's life, i.e., they would increase the fitness of the story. But the decoupling of variation from selection has long been recognized as essential to selectionist theories; as James put it in his essay, it is necessary that they belong to "irrelevant cycles" of causes. Relevance thus constitutes one objection to the selectionist account of culture.

The same transformations block selectionist theories at another point as well, undermining the need for selection by providing another mechanism capable of inducing similar beliefs in a great many heads at once. Sperber imagines our representations (as instantiated in actual brains, not as

abstracta) as elements of the space of a dynamical system, with attractors and basins of attraction. He further imagines that these attractors are the representations of maximum relevance, and that the attractors and basins of attraction of two persons with broadly similar mental contents will also be very similar. But then, from very vaguely related starting-points, those two persons will arrive at very similar ideas about various subjects:

[C]onsider your views on President Clinton. They are likely to be very similar to the views of many, and to have been influenced by the views of some. However, it is unlikely that you formed your own views simply by copying, or by averaging other people's views. Rather, you used your own background knowledge and preferences to put into perspective information you were given about Clinton, and to arrive by a mixture of affective reactions and inferences at your present view. The fact that your views are similar to many other people's may be explained not at all by a copying process, and only partly by an influence process; it may crucially involve the convergence of your affective and cognitive processes with those of many people towards some psychologically attractive type of views in the vast range of possible views on Clinton. [p. 106] (The same mechanisms allow us, for instance, to correct typos, or even to read what we know should have been written in their place, without noticing that it isn't.)

It will not have escaped the attention of certain professionally-deformed readers that this verbal picture cries out for agent-based modeling. This would let us get at questions like when selection is more important than attraction, and the effects of introducing reliable, non-transformative storage --- writing and the kindred arts. There are fascinating issues in evolutionary game-theory as well, since the representational dynamics will to some extent depend on what representations are already held; though not so much as one might suppose. The reason for the limitation is connected to Sperber's account of religion.

Somewhere in the above-mentioned *Philosophical Dictionary* --- the passage eludes me just now --- Voltaire has fun with the effects of trying to believe an impossible or contradictory religious dogma. Sperber explains our ability to do so as follows. We can hold (says Sperber) "reflective" beliefs, "believed in virtue of second-order beliefs about them." There is no reason why these reflective beliefs must be comprehended or even comprehensible by those who hold them. Now, consider the following case. Young Bobby has in his belief box the two representations:

What Mom says is true.

Mom says that God is everywhere.

Bobby does not fully understand how somebody, be it God or anyone else, can be everywhere. However, his mother saying so gives him sufficient ground to exhibit all the behaviors symptomatic of belief: he will readily state that God is everywhere, will assent when the same statement is made by others, and may even refrain from sinning in places where (apparently) nobody can see him. That God is everywhere is for Bobby a reflective belief.... Here is a belief which, like most religious beliefs, does not lend itself to a final, clear interpretation, and which therefore will never become an intuitive belief. Part of the interest of religious beliefs for those who hold them comes precisely from the fact that you are never through interpreting them. While

the cognitive usefulness of religious and other mysterious beliefs may be limited... it is not too difficult to see how their very mysteriousness makes them "addictive." [p. 90]

Reflective beliefs are not limited to such statements as "God is everywhere," but include all of our knowledge which is not either direct perception, or arrived at from direct if not unconscious inference from perception: history, empirical science, most of mathematics. (But not all, apparently: see Stanislas Dehane, *The Number Sense*.) Such "well-understood reflective beliefs ... include an explicit account of rational grounds to hold them. Their mutual consistency and their consistency with intuitive beliefs can be ascertained, and plays an important, though quite complex, role in their acceptance or rejection." By contrast, mysterious reflective beliefs are rationally held (when they *are* rational) solely upon the authority of those whom we learned them from. (Bobby may not be faulted for believing both his mother and his science teachers; but the one authority is valid, and the other a mere phantasm.) Thus, even if Sperber is correct, and the memeticists quite wrong, we do not lose a handy weapon with which to belabor the fanatical and the superstitious.

Sperber's book carries on from the "epidemiology of representations" in two directions. One is an explication of social institutions and social facts. Most if not all of these --- money, say, or marriage, or the existence of a research institute on Hyde Park Road in Santa Fe --- require, or even consist of, shared mental representations. (Money is whatever we all agree is money, be it stone circles, cowry shells, bales of tobacco, appropriately worked bit of soft metals, or the numbers stored in certain bit-fields of certain computers.) This is only going to work if the representations we hold internally are all sufficiently similar that no serious conflict as to our expectations arises: precisely what his conjectured mechanisms are designed to accomplish. This opens the way to fulfilling the demand made long ago by Friedrich Hayek, to "analyze social relations in terms of correspondence and non-correspondence, or compatibility and non-compatibility, of individual aims and desires" and expectations.

The other direction in which Sperber pursues the implications of his basic notion (that "culture is the precipitate of cognition and communication in a human population") is an explanation, grounded in evolutionary psychology and its view of the mind as an agglomeration of specialized modules, of how our representational attractors and basins of attraction form, and of how cultural diversity grows in this uniform mental soil. While this is, again, highly convincing, it defies adequate summary in less than the space (just above thirty pages) in which Sperber expounds it, and accordingly will be left to the reader.

Sperber concludes by reflecting on "What Is at Stake" in a naturalistic account of human culture; these are the dangers of success. (The inevitable charges of reductionism are brushed aside thus: "Let them [the critics] show that the so-called reductionist approaches are ill-conceived, or else let them articulate the moral reasons for their censorship" [p. 152].) The gravest of these is that it might distract the social sciences from their "fundamental role" of "enlightening citizens"; and another, more subtle one.

As in a mirror, we look for our image in the social sciences. When we do not recognize ourselves in the reflected image, we are disturbed. Cognitive psychology does not reflect an immediately recognizable image of ourselves; nor would an epidemiology of representations. Worse, what we

think of as essential and primary --- that is, our existence as conscious persons --- comes out, at best, as a changing pattern, socially projected on to a biological structure, itself precarious. [p. 155]

But Sperber views both of these possibilities as remote dangers, to be overcome by theoretical pluralism and the stubbornness which refuses to see the physical world as the crawling molecular chaos of the physicists.

Sperber's arguments carry conviction, at least at the hand-waving level at which the social sciences are accustomed to conducting themselves. Whether they can be carried further, to precision and even accuracy, is another question, technical and empirical. (It may even be possible to recover a Darwinian-Jamesian-Dawkinsian theory, complete with memes, by treating as equivalent all representations within the same basin of attraction, thus looking at the "slow modes," the infectious transmission that happens after the inner cognitive transformations have come to a halt.) Like the memeticists, Sperber raises the prospect of bringing to life the "specter of a natural science of the social": the question now is whether those dry bones can live.

AN OBJECTION TO THE MEMETIC APPROACH TO CULTURE
In: Robert Aunger (ed.) *Darwinizing Culture: The Status of Memetics as a Science.*

Oxford University Press, 163-173.

By
Dan Sperber

Memetics is one possible evolutionary approach to the study of culture. Boyd and Richerson's models (1985, Boyd this volume), or my epidemiology of representations (1985, 1996), are among other possible evolutionary approaches inspired in various ways by Darwin. Memetics however, is, by its very simplicity, particularly attractive.

The memetic approach is based on the claim that culture is made of memes. If one takes the notion of a meme in the strong sense intended by Richard Dawkins (1976, 1982), this is indeed an interesting and challenging claim. On the other hand, if one were to define "meme", as does the Oxford English Dictionary, as "an element of culture that may be considered to be passed on by non-genetic means," then the claim that culture is made of memes would be a mere rewording of a most common idea: anthropologists have always considered culture as that which is transmitted in a human group by non-genetic means.

Richard Dawkins defines "memes" as cultural replicators propagated through imitation, undergoing a process of selection, and standing to be selected not because they benefit their human carriers, but because they benefit themselves. Are non-biological replicators such as memes theoretically possible? Yes, surely. The very idea of non-biological replicators and the argument that the Darwinian model of selection is not limited to the strictly biological are already, by themselves, of theoretical interest. This would be so even if, actually, there were no memes. Anyhow, there are clear cases of actual memes, though much fewer than is often thought. Chain-letters, for instance, fit the definition. The very content of these letters, with threats to those who ignore them and promises to those who copy and send them, contributes to their being copied and sent again and again. Chain-letters don't benefit the people who copy them, they benefit their own propagation. Moreover, some chain-letters are doing better than others because of the greater effectiveness of their content in causing replication.

Once the general idea of a meme is understood - and especially if it understood fairly loosely -, it is all too easy to see human social life as teeming with memes. Aren't, for instance, religious ideas, with their threats of hell for unbelievers and promises of paradise for the proselytes, comparable to chain-letters, and in fact much more effective in benefiting their own propagation, come what may to their human carriers? More generally, aren't words, songs, fashions, political ideals, cooking recipes, ethnic prejudices, folktales, and just about everything cultural, items that get copied again and again, with the more successful items managing to invade more minds over longer periods of historical time, and to recruit those minds to further their own propagation? If this were so, if culture were made of memes in Dawkins's strong sense, then the study of culture could - and arguably should - be recast as a science of memes or "memetics". The Darwinian model of selection could be used, with proper adjustments, to explain the properties, the variety

and the evolution of culture, just as it explains the properties, the variety, and the evolution of life.

The question is whether the claim that culture is made of memes is a true one. Several objections have been made to this claim. In his "foreword" to Susan Blackmore's *The Meme Machine* (1999), Richard Dawkins responds to the simplest and most serious objection: "that memes, if they exist at all, are transmitted with too low fidelity to perform a gene-like role in any realistically Darwinian selection process" (Dawkins 1999: x).¹ I want here to discuss Dawkins's responses, and, in so doing, develop a different fundamental objection to the meme model. This new objection is that most cultural items are "re-produced" in the sense that they are produced again and again - with, of course, a causal link between all these productions -, but are not reproduced in the sense of being copied from one another (see also Origgi & Sperber, forthcoming). Hence they are not memes, even when they are close "copies" of one another (in a loose sense of "copy", of course).

The objection of low fidelity had been envisaged and taken seriously by Dawkins himself. In *The Extended Phenotype*, he wrote:

"The copying process is probably much less precise than in the case of genes: there may be a certain 'mutational' element in every copying event [...]. Memes may partially blend with each other in a way that genes do not. New 'mutations' may be 'directed' rather than random with respect to evolutionary trends. [...] there may be 'Lamarckian' causal arrows leading from phenotype to replicator, as well as the other way around. These differences may prove sufficient to render the analogy with genetic natural selection worthless or even positively misleading. My own feeling is that its main value may lie not so much in helping us to understand human culture as in sharpening our perception of genetic natural selection" (Dawkins 1982: 112).

Of course, what counts as "too low fidelity" for a given item is relative to the selection bias for that item (see Williams 1966). A greater selection bias allows for a higher mutation rate. On the other hand if, as Dawkins says, there is "a certain 'mutational' element in every copying event" (*loc. cit.*), then it is not easy to see how selection could work at all. It is to this problem that Dawkins now offers an ingenious solution. He uses for this a thought experiment of which I present a simpler but equally effective version (before discussing his version later on). Consider figure 1. A first individual is shown this figure for ten seconds and is asked, ten minutes later to reproduce it as exactly as possible. Then a second individual is shown for ten seconds the figure drawn by the first individual and presented with the same task. This is iterated with, say, nine participants. It is most likely that each drawing will differ from its model and that the more distant two drawings are in the chain, the more they are likely to differ. A judge given the ten drawings in a random order and asked to put them back in the order in which they were produced should perform, if not perfectly, at least much better than random. The "mutational elements" in every copying event are such that a drift is manifest, and no stable pattern is maintained.

Figure 1

Now imagine a similar experiment being performed, but this time with figure 2 as initial input. Again, each drawing produced by the successive participants is certain to differ from its model, since each participant will fail to reproduce the model in all its particulars. This time, however, the distance in the chain of two drawings on the one hand, and their degree of difference on the other hand should be two variables independent of one another (or nearly so). A judge asked to put the ten drawings in the order in which they were produced should be unable to do better than random. In spite of low fidelity of copying, a stable pattern is most likely to endure across versions, and individual variations are very unlikely to compromise this pattern.

Figure 2

What explains the difference between the two experiments? In the case of figure 1, people try and form a mental image of a drawing which they don't recognize in any way, and then try and reproduce this mental image on paper. In storing the information, in recalling it, and in

reproducing it, they are likely to introduce unintended variations that are either in random directions, or are in the direction of entropy, that is, plain loss of information. In the case of figure 2, people recognize the figure as a five-branched star drawn without lifting the pencil. They may well forget most of the other particulars of the drawing under their eyes, such as length of relatively straight segments, or angles. Still, they will produce another star of the same type.

Dawkins might describe the difference between the two types of tasks as follows. In tasks of the first type, what gets copied is the product, the drawing. There is no difference therefore between the "phenotype" and the "genotype", and phenotypic variations are also genotypic variations. In cases of the second type, what gets copied is the implicit instruction ("draw a five-branched star without lifting the pen"). These instructions are the true genotype, while the drawings are only phenotypes. Each participant in the experiment assumes that the preceding participant merely intended to follow the implicit instruction and that imperfections or idiosyncrasies were unintended and should be ignored. Individual variations in the productions of the phenotype do not matter. They are not genuine mutations. "The instructions," writes Dawkins "are self-normalizing. The code is "error-correcting" (p. xii).

Dawkins concludes the argument by stating: "I believe that these considerations greatly reduce, and probably remove altogether, the objection that memes are copied with insufficient high fidelity to be compared with genes. For me the quasi-genetic inheritance of language, and of religious and traditional customs, teaches the same lesson." (p. xii) In other terms, the stability of cultural patterns is proof that fidelity in copying is high in spite of individual variations. These variations are phenotypic, not genotypic, and Darwinian selection can take place without being jeopardized by too high a rate of mutation.

I, on the other hand, believe that what is here offered as an explanation is precisely what needs to be explained, what is offered as a solution is in fact the very problem to be solved. Saying that the instructions are "self-normalizing" amounts to resolving a problem by invoking a mystery. The type of thought experiment proposed by Dawkins is well worth analyzing so as to solve the mystery. The conclusions I draw from this thought experiment are, however, very different from Dawkins's. They point to yet another difficulty with the meme model.

Let me grant forthwith two points to Dawkins:

(a) Of course, one item A can be a replica (in the relevant sense) of another item B without being identical to B in every respect. From a memetic point of view, it is enough that A and B should share the properties the recurrence of which one is trying to explain.

(b) Of course, cultural items exhibit, over periods of time of various length (longer for folktales, shorter for modern dress fashions, for instance), the kind of stability found, on a much smaller scale, in Dawkins's thought experiment. That is, although there is much individual variation, items of the same type all remain in the vicinity of one another and instantiate a common pattern. The issue is whether the relative stability found in cultural transmission is proof of replication. Dawkins seems to think it is. In substance, he proposes a test to decide whether a causal chain that links the production of a series of items is a chain of replications. The test is as follows.

Present (or suppose you present) to an intelligent observer the items in the chain in a random order. If the observer finds it impossible to put back, at least approximately, the items in the order in which they were produced, then these items are replications in the relevant sense. Individual variations among these items are phenotypic and do not compromise the stability of the underlying genotype. Much of culture passes this test and is seen, then, as made of replicators.

To show that Dawkins's test is not as reliable as it may seem, let me first give an example of a causal chain that would meet the criterion, but could not be properly described as a case of memetic transmission. Consider the case of laughter. Laughter is a social behaviour that is typically triggered, in individual development, by the laughter of others, and that remains a highly contagious form of behaviour. Laughter is influenced in its intensity, style, and circumstances of arousal by cultural factors. Moreover, even within a cultural group, there are important individual variations. Now, imagine a series of registrations of causally linked individual laughters (linked either in the stabilization of laughing behaviour across generations, or in a much shorter causal chain of contagious laughter). If these registrations were presented in a random order, they could not, I take it, be rearranged in their causal order. Laughter passes Dawkins's test. Yet, surely, it is not a meme.

Why is laughter not a meme? Because it is not copied. A young child who starts laughing does not replicate the laughters she observes. Rather, there is a biological disposition to laughter that gets activated and fine-tuned through encounters with the laughter of others. Similarly, an individual pushed into convulsive laughter by the laughter of others is not imitating them. The motor program for laughing was already fully present in him, and what the laughter of others does is just activate it.

Let me generalize and define three minimal conditions for true replication. For B to be a replication of A,

- *B must be caused by A (together with background conditions)*
- *B must be similar in relevant respects to A*
- *The process that generates B must obtain the information that makes B similar to A from A.*

Another way to express this third condition is to say that B must inherit from A the properties that make it relevantly similar to A. Discussions of memes take implicitly for granted that the co-occurrence of causation and of similarity between cause and effect is sufficient evidence of inheritance. But this is not so. The cause may merely trigger the production of a similar effect, as we saw with the case of laughter. Even if conditions (1) and (2) are satisfied, condition (3) may not be.

Consider a theoretical example, with two cases to be compared. In both cases conditions (1) and (2) are satisfied, but condition (3) is satisfied only in the second case. *First case:* Ten sound-recorders with the same repertoire of melodies in each have been fixed so that they are activated by the sound of the last five bars of any melody in their repertoire, and then play this very melody. They are placed in such a manner and at such a distance of one another that the first one

activates the second, the second the third, etc. The first recorder plays melodies in random order at appropriate time intervals. *Second case*: Ten sound-recorders have been fixed and placed so that the second recorder records sound from the first, and then replays it, the third recorder records sound from the second and then replays it, and so on. Only the first recorder has a ready repertoire of melodies, and it plays them in random order at appropriate time intervals. In both cases, an observer listening to these devices playing, each in turn, one melody after another, and unable to inspect them otherwise, would have some reasons to think she was witnessing a series of replications. In fact, this would be true in the second case, but not in the first, where only triggering takes place and no copying at all. This illustrates the point that, in the case of a causal chain that satisfies conditions (1) and (2), further evidence about the causal processes involved must be available before one is in a position to argue that condition (3) is also satisfied, and that one is dealing, therefore, with a true chain of replications.

Let us go back, now, to our thought experiment. In the first task (memorizing and reproducing figure 1), participants rely on general perceptual, memory and motor abilities. In other terms, they rely on the general human ability to imitate, an ability which is taken by memeticists to be extremely powerful. In this case, however, it fails. In the second task (memorizing and reproducing figure 2), the stimulus is *recognized*. That is, it triggers the activation of pre-existing knowledge. The stimulus is categorized as a token of a general type: a five-branched star drawn without lifting the pencil. Properties of the actual stimulus that are irrelevant to this categorization are just ignored. When asked, after ten minutes, to reproduce the stimulus, participants just produce another token of a five-branched star without, in most cases, even trying to remember what the original figure exactly looked like. Their ability to perform well in this second task is not an ability to perceive and copy. It is an ability to recognize and re-produce, using, for this, knowledge of the five-branched-star type that they already possessed before encountering the token. It is not, then, that people are better at imitating figure 1 than at imitating figure 2. They are indeed bad at imitating figure 1, and they are not imitating figure 2 but merely producing a new token of the same recognizable type.

Dawkins's original thought experiment involved a comparison of two tasks: reproducing a drawing of a Chinese junk, or making an origami Chinese junk after having been taught, by demonstration, how to make one. Unlike my simpler version, the two final products - the drawing or the origami - are recognized by the participants. In the drawing version, however, participants are unable to recognize the series of strokes that would yield the full drawing, whereas in the origami version the successive foldings are individually demonstrated. Thus, the two tasks are different, not just in the type of item to be copied (a drawing vs. an origami) but also in the fact that participants observe only the product in the first task, and the process of production in the second task. If participants were just shown a finished origami junk, they would, presumably, do even worse in reproducing it than in reproducing a drawing of a junk.

The crucial difference between the two tasks is that the second involves demonstration and the other not. From the demonstration, or so Dawkins assumes, participants can and do infer implicit instructions (e.g. "take a square sheet of paper and fold all four corners exactly into the middle"). These instructions are not a description of what the person making the origami is actually doing (the four corners are never folded exactly into the middle, for instance) but a description of what the person is aiming at, is intending to do. Inferring instruction involves much more than the

ability to perceive and describe actual movements; it involves the ability to attribute goals and intentions.

Contrary to what Dawkins writes, the instructions are not "self-normalizing". It is the process of attribution of intentions that normalizes the implicit instructions that participants infer from what they observe. When you see the person folding the four corners of a square sheet of paper into four different points in the vicinity of the middle, you assume that she was aiming at the middle rather than at these four odd points. Such intentions to realize regular geometrical pattern are familiar - in particular in the context of origami - and readily attributed. You recognize, in other terms, the behaviour as an imperfect realization of an intention of a familiar and regular type rather than as the perfect realization of an intention of an unfamiliar and irregular type. The instructions that you infer are, then, informed in part by what you actually observe, and in part by what you already know of human intentions, and of the type of instructions typically used in origami.

The instructions are not being "copied" in any useful sense of the term from one participant to the next. Certainly, instructions cannot be *imitated*, since only what can be perceived can be imitated. When they are given implicitly, instructions must be inferred. When they are given verbally, instructions must be comprehended, a process that involves a mix of decoding and inference (Sperber and Wilson 1995). The inference involved in either case draws on domain-specific competencies having to do with the attribution of intentions and with knowledge of the role of regular geometric forms in the formation of human intentions generally, and in paper folding in particular. Thus the normalization of the instructions results precisely from the fact that something other than copying is taking place. It results from the fact that the information provided by the stimulus is complemented with information already available in the system.

In the real world, and in particular in the cultural world, triggering and copying can and do combine in various degrees. What gets being triggered by cultural stimuli are acquisition mechanisms and competencies that are more or less domain-specific. These mechanisms are themselves in part genetically, in part culturally inherited.

Let us briefly consider the example of the acquisition of language. In acquiring a language, a child internalizes a grammar and a lexicon on the basis of linguistic interactions. Nowhere in these interactions, nowhere in the linguistic data is the child presented with the grammar present to be copied. Rather the grammar must be inferred from these data. As Noam Chomsky has long argued and as has become, if not universally, at least generally accepted today, this requires a genetically determined preparedness to interpret the data in a domain-specific way and to generalize from it to the grammar of the language, going well beyond the information given. Imitation in some sense may well play a role - though not a sufficient one - in the acquisition of the phonology of words, but not in the acquisition of their meaning. Meaning is not something that can be observed and copied. It can only be inferred. Language learners converge on similar meanings on the basis of weak evidence provided by words used in an endless diversity of contexts and with various degree of literalness or figurativeness. Acquisition of meaning in such conditions is a feat that would be wholly mysterious if it were not highly constrained by domain-specific competencies having to do with conceptual domains on the one hand and with the attribution of communicative intentions to speakers on the other hand. Thus the similarities

between the grammar and lexicons internalized by different members of the same linguistic community owe little to copying and a lot to pre-existing linguistic, communicative, and conceptual evolved dispositions.

The respective role of copying and that of pre-existing dispositions to construe evidence in domain-specific structured ways may vary with different cultural competencies. Learning to tap-dance involves more copying than learning to walk. Learning poetry involves more copying than learning philosophy. For memetics to be a reasonable research program, it should be the case that copying, and differential success in causing the multiplication of copies, overwhelmingly plays the major role in shaping all or at least most of the contents of culture. Evolved domain-specific psychological dispositions, if there are any, should be at most a relatively minor factor that could be considered part of background conditions. There is nothing obvious about such a view. While the view may have some popularity about unconcerned lay people, no psychologist believes that cultural learning is essentially a matter of imitation (this is true even of psychologist who attribute an important role to imitation, e.g. Meltzoff & Gopnik 1993, Tomasello & al. 1993). In fact, such an idea goes against all major recent developments in developmental psychology and in evolutionary psychology (see Hirschfeld & Gelman 1994). This, together with the problem raised in this article, puts a special burden on memeticists.

Memeticists have to give empirical evidence to support the claim that, in the micro-processes of cultural transmission, elements of culture inherit all or nearly all their relevant properties from other elements of culture that they replicate (i.e. satisfy condition 3 above). If they succeeded in doing so they would have shown that developmental psychologists, evolutionary psychologists and cognitive anthropologists who argue that acquisition of cultural knowledge and know-how is made possible and partly shaped by evolved domain-specific competencies are missing a much simpler explanation of cultural learning: imitation does it all (or nearly so)! If, as I believe, this is not even remotely the case, what remains of the memetic program? The idea of a meme is a theoretically interesting one. It may still have, or suggest, some empirical applications. The Darwinian model of selection is illuminating, and in several ways, for thinking about culture. Imitation, even if not ubiquitous, is of course well worth investigating. The grand project of memetics, on the other hand, is misguided.

Note

1. Dawkins adds: "The difference between high fidelity-genes and low-fidelity memes is assumed to follow from the fact that genes, but not memes, are digital." The objection that memes are transmitted with too low fidelity can be made without this further claim, which I find vague and unconvincing.

Abstract

Song (musicality, singing capacity), we argue, underlies both the evolutionary origin of human language and its development during early childhood. Specifically, we propose that language acquisition depends upon a Music Acquiring Device (MAD) which has been doubled into a Language Acquiring Device (LAD) through memetic evolution. Thus, in opposition to the currently most prominent language origin hypotheses (Pinker, S. 1994. *The Language Instinct*, W. Morrow, N.Y.; Deacon, T.W. 1997. *The Symbolic Species*, W.W. Norton, N.Y.), we contend that language itself was not the underlying selective force which led to better speaking individuals through natural selection. Instead we suggest that language emerged from the combination of (i) natural selection for increasingly better mental representation abilities during animal evolution (thinking, mental syntax) and (ii) natural selection during recent human evolution for the human ability to sing, and finally (iii) memetic selection that only recently (within the last 100,000 years) reused these priorly evolved abilities to create language. Thus, speech - the use of symbolic sounds linked grammatically - is suggested to be largely a cultural phenomenon, linked to the Upper Paleolithic revolution. The ability to sing provided the physical apparatus and neural respirational control that is now used by speech. The ability to acquire song became the means by which children are able to link animal mental syntax with syntax of spoken language. Several studies strongly indicate that this is achieved by children through a melody-based recognition of intonation, pitch, and melody sequencing and phrasing. Language, we thus conjecture, owes its existence not to innate language learning competencies, but to innate music-associated ones, which - unlike the competencies hypothesized for language - can be straightforwardly explained to have evolved by natural selection.

The question on the origin of language then becomes the question on the origin of song in modern humans or early *Homo sapiens*. At present our ability to sing is unexplained. We hypothesize that song capacity evolved as a means to establish and maintain pair- and group-bonding. Indeed, several convergent examples exist (tropical song birds, whales and porpoises, wolves, gibbons) where song was naturally selected with regard to its capacities for reinforcing social bonds. Anthropologists find song has this function also amongst all human societies.

In conclusion, the ability to sing not only may explain how we came to speak, but may also be a partial answer to some of the very specific sexual and social characteristics so typical for our species and so essential in understanding our recent evolution.

Keywords: origin, human, language, natural selection, cultural evolution, music, intonation, rhythm, song, children

1. Introduction

1.1. Memetics and the origin of language

A major topic of memetics is the transmission of information by words. Thus better knowledge about the origins of language could throw light on many of the issues that are presently debated in memetics. Understanding what language is about is also important because it can be put that language is the only essential difference between human and animal existence, a difference which enables to explain most or all of the features characteristic for human psychology and human behaviour (e.g. [92]), which in turn explains why some memes - which we define broadly as bits of behaviourally transmissible information [Note 1] - are spread more successfully than others [Note 2].

Finally, memetic selection tends to get ignored by theories seeking to explain the origins of language. Most prominent theories instead argue for a gene- rather than meme-based origin. Some, for example, conjecture that language arose from Darwinian, adaptationist selection processes by which better speakers had greater reproductive success (Pinker [67], Smith and Szathmary [83]). Also Deacon [21] relies on genes (genetic assimilation of phenotypic characteristics (Baldwinian evolution)) and long term evolution to explain how language could arise, although memes (i.e. the use of symbols) already play an important role in this Baldwinian evolution. To the opposite, the memetic selection hypothesis defended here assumes that all preadaptations for language production and language understanding were naturally selected for other reasons than language, wherefrom language emerged and evolved rapidly and only recently by a process of cultural evolution. Thus, we do not reject natural selection - indeed, our approach largely depends upon it - but we try to understand how and when cultural/memetic selection comes into play and eventually takes over. The emergence of language in a human community by interaction between humans and symbols is not specifically addressed here, but will be the issue of a forthcoming paper [82].

1.2. The evolution of information and language

Informationally, 'life' can be considered as a giant chemical process which took off some 4 billion years ago - with the origin of the first self-replicating cell (also see [Note 2]). For instance, the product of one enzyme can be used as the substrate for other enzymes, cells interact by means of hormones, humors and neurotransmitters and multicellular colonies do so by means of pheromones and scent molecules. And across these organisational levels, the interactions between enzymes enable cells to interact by means of hormones, humours and neurotransmitters, while the cellular interactions enable multicellular colonies to interact by means of pheromones and scent molecules.

When brain (and eye and ear) possessing animals arose, a new manner of information transmission was introduced into biology. Now, living creatures could exchange information in a nonchemical manner through sound and sight, which increased the speed and the flexibility of informing each other and of influencing each other's behaviours or of adapting one's behaviour to the cues provided by others, i.e. behavioural instead of chemical interaction. One of the characteristics of such information is that it is 'inherited' in a nongenetic manner [35, 93]. One easily imagines how it is impossible to inherit rules for complex social behaviour genetically while on the other hand such morals, habits are readily 'learned' (rather: assimilated, absorbed) by young animals, e.g. through (emotional) punishment and reward (also see [Note 1]).

Dawkins [20] has called these 'culturally inherited' bits of information, 'memes'. Their development went hand-in-hand with parallel evolution of semantic abilities: these signals have to be turned by the brain into information that can be processed by cells that interact chemically (that is, by neurons and their information transmission by neurotransmitters). For example, an alarm cry (auditory cue) has to get linked/recoded by semantic abilities into the neurological (biochemical) concept or category or mental representation of 'dangerous situation'; this then triggers the various neurotransmitter- and/or hormone-transmitted cellular interactions that occur in fright and fear.

Importantly, the alarm cry is already here functioning as a kind of symbol, since similar sounds or signs may have a completely different meaning depending on the situation or the species. The full progress to symbolism in communication - spoken language as used by humans - requires that further encoding takes place: not only are symbols (words or signs) linked to mental images (linguistic semantics), but also word order, affixes, and other morphological modifications/operations/processes enable the communication of relationships between representations (linguistic syntax). Of course, the possibilities for individual thinking and for information transmission between individuals as a result of symbolic language are increased exponentially again.

1.3. The major questions about language

Two questions exist about language development and its origins.

First, 'How is it that the complex phenomenon of spoken language arose in the animal world?'

Second: 'How is it possible that children acquire language with such ease irrespective of the language they learn?'

We argue that none of the presently available hypotheses [21, 67] provide final answers to the questions about the origin of language both during phylogeny of the human kind and during ontogeny of the individual human being. First, we briefly review the present dominant approaches.

The present prominent hypothesis on the phylogenetic origin of language is the natural selection approach. This claims that speech - and its associated characteristics like voice, and specialized brain regions and the ability to comprehend syntax of spoken language - was selected by gradual natural selection of genetic changes, made possible by the selective advantage of speech itself [66, 67, 83] or was made possible by genetic assimilation [21].

The present prominent hypothesis on the origin of language during individual ontogeny [16, 17] - a hypothesis taken for granted by e.g. Pinker [67] and Smith and Szathmari [83] - is that children have a language acquiring device (LAD), that uses an innate Universal Grammar. Syntax, according to this view, is acquired by a child by setting a few parameters of the 'innate grammar' according to those in their parent's language.

In this paper, we argue, in opposition to these approaches, first that song production and song interpretation capacities were the essential, naturally selected, preadaptations that enabled language, which readily evolved in a cultural (memetic) manner. In other words, speech preadaptations were naturally selected but only in regard to singing and not in regard to the later use they came to have in language. Second, linked to this 'song being the preadaptation for speech' approach, we argue that children learn spoken language by means of innate melody recognition capacity (Music Acquisition Device or MAD). If genetic evolution contributed to our abilities to learn language, it was in an indirect manner by providing us with abilities to sing. Thus, language learning devices can in fact be considered as memetically adapted song learning ones.

2. Language components

2.1. Four competencies

The capacity to produce and comprehend spoken information presupposes several cognitive abilities.

2.1.1. Mental semantics

The mind must be able to make mental images (virtual representations) that represent externally perceivable objects, agents and situations.

Furthermore, the mind must be able to semantically link sounds (or visual signals in animal behaviour, writing or sign-languages) to these mental representations to enable their communication, i.e., to make sense of them or to convey meaning. These links are symbolic - that is arbitrary or established by convention. This is illustrated by the fact that many words exist in different languages for the same concept or thing. Accordingly, many completely different writing conventions exist.

2.1.2. Mental syntax

The mind must be able to establish the relations and interactions between these representations, whereby some are active or originators (agents, subjects), while others undergo a change in situation or receive actions (patients, objects).

2.1.3. Vocal flexibility

Spoken language depends on the vocal dexterity to produce a wide range of consonants, vowels and intonations.

2.1.4. Linguistic syntax

The mind must be able to process the word order, syntactic 'roles' such as verb, subject and morphological modifications (syntactic affixes and internal phoneme changes) so that it can produce and comprehend them when communicating with others.

2.2. Evolution of mental semantics and mental syntax (the first two competencies)

2.2.1. Mental representation and semantic ability

The ability to form mental representations, mental images of the environment and to categorize these objects does not need explanation in the context of the origin of language. It is clear that categorization and generalisation is a selectively advantageous trait to any heterotrophic, multicellular, mobile, brained organism (i.e., to most animals), since this enables an animal to reduce the reaction time upon perception. If animals, for example, could not generalize the concept of a certain species of tree, they would be forced to investigate each tree as to whether its fruits were edible. It is easily understood how better and better mental representation or categorization capacities were continuously naturally selected for throughout animal evolution. We define semantic skill as the ability to link visual or auditory stimuli to a mental representation. This skill is nothing new as animals readily assign meaning to auditory or visual signals. For example, a dog observing a bell ringing will quickly learn to link it to the subsequent appearance of food - Pavlovian conditioning. The dog's brain finds no difficulties in linking an arbitrary sound to an internal representation of a real or possible event. Such semantic abilities can be expected to have been selected particularly for auditory and visual signalling to aid communication between members of a species. Thus, social animals seem well equipped to acquire and use culturally inherited semantic meanings.

The semantic ability to link auditory sounds and visual signs to meaning, it should be noted, lies at the heart of culture, and of memes (see also 1.2). Culture, indeed, can be broadly defined as the exchange of information by auditory and visual behavioural cues. Thus, semantic ability enables the existence of behavioural memes (cry x means danger, sound y means anger, melody z means affection ...) that survive as replicated bits of information with high heritability within learnt culture. This can be seen in the rules for social behaviour that get culturally, behaviourally, memetically inherited among social animals from generation to generation. The composition of memes in an animal culture is often more stable than the genetic composition of the population. These behaviours are the forerunners of the symbolic memes.

It should be noticed that linking arbitrary sounds (words) to specific meanings in essence requires no novel skills: also dogs can learn it. From this it follows that we do not need to explain any quantitative differences in semantics. All we need to explain is why humans are so good at this.

2.2.2. Mental syntax

Also we need not explain the existence of mental syntax in the context of language development: the expansion in thinking and intelligence by means of increased mental syntactical abilities is

observed throughout vertebrate and invertebrate taxa. Animals recognize different agents and their interactions and the causal links between ongoing processes connecting them. We have now plenty of examples of mental representation possibility and of generalization, categorization and causal reasoning, i.e. thinking in animals [36, 37, 40, 53]. There is now strong indication that chimps even succeed in forming mental representations of the knowledge present in the mind of another subject [Note 3].

Mental syntax offers a strong selective advantage because it enables animals to predict possible outcomes of current situations (aided by memory of past events and their outcomes) and it helps them to make the best choices between different possible actions.

2.2.3. Conclusion

We conclude that mental representation and semantics (linking of observable behaviour to a mental representation or conveying meaning to an observation) on the one hand and mental syntax (recognition of causal links) on the other hand are two abilities that were naturally selected for long before humans appeared and long before the rise of spoken language. Before we explain how vocal flexibility and linguistic syntax arose, we will briefly summarize why we need other hypotheses than those proposed by Chomsky [16, 17], Pinker [67] and - to a large extent - Deacon [21].

3. Problems with Chomsky, Pinker and Deacon

3.1. Noam Chomsky: Is there a universal grammar?

Chomsky [16, 17] argues that syntactical skills are novel to human communication, arising in each variety of human language from parameters set in an innate Universal Grammar. However, current knowledge does not provide evidence of something like innate Universal Grammar. A peculiar feature of human language is the high degree of diversity in each of its characteristics. For example, in configurative languages - like Indo-European languages, subject (S), object (O) and verb (V) can mathematically be ordered in 6 manners. Although SOV (45%) and SVO (42%) are predominant [1], five of the six possibilities are used (there are no examples known of OSV), by itself a strong indication that almost any conceivable order can be used. Some languages (like Dutch) also use mixtures of SOV and SVO, dependent on the hierarchical position of the sentence. Even more curiously, there are nonconfigurative languages, like Guugu Yimidhirr from N.E. Australia (see also below).

Aitchison has reviewed the difficulties in finding underlying universal rules in grammar of spoken languages [1].

However, to Chomskyans all this diversity is an illusion and under the surface all of these languages are dialects of 'earth speak' - as Pinker [67] puts it. The syntactical differences are due to different parameter settings given to an innate Universal Grammar. There is a problem with this answer: the notion of Universal Grammar, frankly, is philosophical speculation. We refer to Botha [11], Harris [39], Tomasello [89], Allot [3], Bates & Goodman [6] for useful sources underpinning our skepticism. This nonfactual status of the Universal Grammar hypothesis has

been ignored since Chomskyans have been remarkably successful in promoting the idea that Universal Grammar is to language what molecules are to chemistry, gravitation to astronomy or DNA to biology - an established fact.

Not only is 'universal grammar' not universal, it does not even concern many aspects of grammar. Really 'odd' languages exist like Nootka and Mohawk, (two Native American languages), Lisu from Burma and Mam from West-Guatemala. The latter for example has a rich vocabulary for the action of laying, depending on the position of laying (on belly, on back, on side), depending upon whether a human or an animal is laying, upon telling whether one lays sick or drunk, etc.). Some languages have no gender classes, some two, other three and Sotho even has six. Furthermore, languages use a limited subset from 757 phones (observed in a total of 317 languages) very differently. They do so with a varying number of consonants and vowels from as low as 11 in the case of the Polynesian Mura to 148 in the African !xu or !Kung. Most average between 20 and 35 [52]. This is not explained by Chomskyan theory.

It appears that 'Universal Grammar' is not a scientific fact but a program which for theoretical reasons assumes that language has a universal core. It is an assumption which Chomskyans have constantly failed to establish. Chomskyan linguistics, we further note, is ignored by many linguists. Rather than being the only approach to grammar - as has been suggested by Pinker [67], it is only one of several. Further, the people who we might expect to make use of it - that is those seeking to computerise speech, completely ignore Chomskyan theory. Also many cognitive psychologists reject it as it fails conspicuously to fit the process by which syntax is acquired by children [6].

The noncredibility of 'Universal Grammar' leaves us with a hard problem: how could natural selection have created the diversity we find amongst human languages? Diversity does not offer the user of any language any advantage. (The only people, we might note, that gain from it are linguists who can make careers based upon studying obscure languages).

In the case of phonetics this is particularly problematic since it is known that infants before nine months are prepared to hear the phone contrasts present in all languages [27, 86, 90], an ability which is lost once they are familiar with their own language [4]. What advantage could exist for such an ability?

This is an unacknowledged but puzzling anomaly in the evolution of phonology and one can wonder why there should exist such a variety when only a small subset of phones (roughly one in twenty to one in forty) are used in any particular language.

In our opinion, this diversity creates work for phoneticians, but it makes no sense evolutionary, except in one circumstance: that linguistic evolution was not responsible for selecting the processes responsible for phone differences but instead co-opted existing diversity to the - phonetically more limited - needs of speech. In this view, speech evolution limited itself to developing means to use preexisting information processing sensitivities in the temporal/parietal and motor cortices.

In fact we know this is the situation in phonetics: animals as different to us from chinchillas [46] to quails [45] can hear phones. The auditory cortex of monkeys is as able as that of humans to hear the auditory features which characterise phones [85]. Neurons in the homologous areas to Wernicke's area process phonetic parameters such as fundamental frequencies, voice onset times and place of articulation (for instance, [85]). Phonetics appears to be a case where an important component of speech was not a direct product of natural selection but one that came about from a reuse of processes that had been already evolved much earlier for other reasons.

In conclusion, although we argue that something like universal mental syntax exists (see 2.1.2), we fail to see how spoken syntax could rely on a universal linguistic grammar.

3.2. Steven Pinker: Is it plausible to assume that natural selection for better speech capacities could have happened?

3.2.1 Introduction

Can language be understood as 'an organ', a 'language instinct' [67], that was developed by gradual natural selection in which better speakers had more reproductive success, resulting in the selective survival of genes encoding for such better language abilities?

Pinker [67] and Pinker & Bloom [66] have suggested that the Chomskyan innate Universal Grammar arose by natural selection. There are many problems with this proposal. Bickerton [9], for example, in spite of being committed to the idea that an innate Universal Grammar arose by natural selection, felt the problems of this happening were so great that it could only be explained by a single and extraordinary macromutation, which is clearly unacceptable to any evolutionary biologist.

The following quote summarizes how Pinker and Bloom [66] propose that natural selection could have played a role in the development of language:

"Furthermore, in a group of communicators competing for attention and sympathies there is a premium on the ability to engage, interest, and persuade listeners. This in turn encourages the development of discourse and rhetorical skills and the pragmatically-relevant grammatical devices that support them. Symons' [87] observation that tribal chiefs are often both gifted orators and highly polygynous is a splendid prod to any imagination that cannot conceive of how linguistic skills could make a Darwinian difference."

Below are some of our objections.

3.2.2. Language genes

Natural selection for language only works if it can be genetically inherited. However, thus far no language genes have been reported in spite of intensive searches that have been made for inherited disorders of language. The case of the family known by the initials KE with an inherited disorder demonstrates the failure of this search, paradoxically by the enthusiasm with which this example has been misreported as an inheritable language disorder. From early on in

life members of this family suffer a devastating neurological dysfunction that requires many of them to communicate by sign-language. The disorder affects the coordination of orofacial musculature, both for nonlinguistic uses and for speaking. The syntax problems of these people are reported as their primary problem by those seeking a gene specific for language [32, 33, 67]. Still, recent clinical reports upon this family stress that this claim is false since virtually all aspects of their expressive language - from syntax to articulation - is found impaired [30].

However, let us suppose - for the sake of argument - that specific language abilities are genetically encoded. Would such genes increase the reproductive success of better speaking individuals? There are several problems, some of which are addressed below.

3.2.3. Individual vs group fitness

First, the advantages offered by speech, like more successful hunting, would have benefited all individuals in a hunter-gathering band of early humans, even those with less well developed language capacities.

Indeed, better communication possibilities favour the group (or the species) as a whole and as such it seems implausible that natural selection, which works on differential reproductive success of specific genes, could have worked at all. Group selection means here that reproduction of all genes present in a group is influenced in a similar manner by newly developed behaviours. Accordingly, Allott [3] notes:

"However, in the case of humans there can also be cultural selection, behavioural selection at the group level, where the patterns of behaviour adopted are not tied to individual genetic differences."

Although Ridley [70] has convincingly argued that in nature group selection usually is a much weaker selective force compared to natural selection, in cases where memetic information transmission plays a role (like in imitating/learning behaviour) we might understand easily how group selection could play its role in evolution. Changes in individual behaviour - regardless whether these changes are genetically encoded or not - can be taken over by other members of a group. In case this behaviour happens to confer some selective advantage, every member of the group can quickly profit of this, regardless the genetic make-up of the individual. Certain groups as a whole then may be favoured since they acquired some behaviour. Therefore an initial coincidental link will exist between certain behaviours (memes) and the collection of genes which happen to be present among the group members with this behaviour. So, all individuals and genes will be favoured, and this will obscure natural selection for the gene which possibly led to the successful behaviour. Moreover, many complex social behaviours do not have a genetic basis but can originate as coincidental inventions of some individual (see the example of Japanese macaques below and our remarks on language genes (3.2.2)).

Taken to its extremes, Pinker's claim that the complexity of language arose as a gradually selected feature compares to stating that our tool making refinements were a consequence of genetic selection. As such, people who had a mutant gene which gave them the possibility to keep a fire burning were reproductively more successful than those without the gene. A later

mutant enabled some to make fire by firestones and his/her offspring was reproductively more successful than people who did not possess this genetically encoded capacity, because it is obviously more advantageous to be able to make your fire yourself whenever you want to. Thus the gene for making fire with firestones spread in the population and outcompeted the 'keep the fire burning' gene. Of course, the genetic mutants which could make matches were better off and outcompeted the firestone firemakers through better reproductive success. But alas, present day mutants which use lighters are competing out the match using genetic mutants.

The silliness of this argument is obvious. Still, this is largely what is being claimed by the gradual natural selection approach of Pinker about the origin of language. Moreover, it is even far more difficult to explain selection of language this way than it is to explain tool use (see 3.2.7).

3.2.4. Can language be explained by assuming better reproductive success of better speakers due to an increase of social status?

Even in the case of genetic encoding of cultural phenomena like language, and even in case where individuals gain a higher social status which results from their socially highly valued and (for the sake of the argument) genetically encoded cultural behaviour (but see 3.2.5), this new skill which is first owned by an individual with a mutant gene or a novel recombination of genes, must remain hidden to other members of the species. Because of mimicking capacity, other members will readily copy the art such that the eventual higher social rank brought by the new trick and which might lead to more successful reproduction, is readily lost. The mutant parent even must hide this skill for its own offspring, otherwise both mutant and wild type offspring will take advantage of it, and again no natural selection will be possible.

The example of the Japanese macaques who readily adopted washing sand from sweet potatoes as it was first done by one member of the group is well known (see [Note 1] for remarks on imitation). Whether or not this single group member had some gene for this behaviour (which we heavily doubt), the gene could not lead to higher social status as a result of the behavioural change it introduced, since several group members readily behaved the same way.

3.2.5. Does better speech production really bring along a higher social status?

Pinker [67] claims that people with better speech capacities have more chances to acquire a higher social rank, becoming a tribe leader or politician, and from this it is inferred that they will have higher reproductive success leading to spread of genes for better speech.

However, there are several pitfalls in this line of reasoning. First, one should not confuse current macrosocial politics - where indeed leadership often has to do more with ones' public image, which indeed partially depends on ones' linguistic capacities - with the original small tribe politics. Under these original conditions, being the leader is often the mere consequence of having a father who was the previous leader, regardless one's (linguistic) skills. Second, one can question whether it were especially better speech capacities which led to high social rank and thus reproductive success. Being a successful hunter, a good parent, an efficient food gatherer, a socially enjoyable person (which depends not necessarily on speech capacities), a very

aggressive and physically strong male or a good singer or a sexually attractive partner, are all other and probably more important reasons of why an individual could be reproductively successful. Physical attractiveness may even be a more important reason for reproductive success than social rank in humans (see 3.2.6) and later on we will argue in favour of the attractiveness of male singers - above male orators - on females (see 3.2.5). Whatever, it appears that natural selection will be too weak a force to explain language by the social status it might provide, since speech happens to be only one of many possible other factors which determine social status.

Anthropological studies moreover show that in the small hunter-gatherer bands, the 'big man' is not distinguishable from the other members of the band [25, 26]. To quote Richard Lee upon the hunter-gatherer !Kung: 'None is arrogant, overbearing, boastful, or aloof. In !Kung terms these traits absolutely disqualify a person as a leader and may even engender forms of ostracism... Another trait emphatically not found among traditional camp leaders is a desire for wealth or acquisitiveness... Whatever their personal influence over group decisions, they never translate this into more wealth or more leisure time than other group members have' [47]. The kind of social organisation (tribes and kingdoms) which Pinker has in mind and where speech eventually might have increased social status, eventually (but doubtfully, see 3.2.6) leading to a minor reproductive advantage, does only exist since about 10 000 years, well after the origin of language [25, 26].

3.2.6. Does higher social status ensure reproductive success?

There is strong evidence - for example from analogy with social animals - that reproductive success is indeed closely linked to social rank.

However, just in case of humans - where this link between social status and reproductive success is needed most to supply natural selection as an explanation for language - it may not strictly be applied.

Humans, living in fission-fusion societies with strong pair bonding and with prolonged periods of absence of the males, appear to be a special case. It has been suggested that females indeed do prefer partners for life with high social rank, thus ensuring material advantages for raising offspring, but that they try to choose physically - genetically attractive partners for sexual reproduction. Strong evidence for adulterous behaviour of females - at least in original human tribes - comes from the many highly complicated adaptations of both female and male reproductive behaviour at the level of oocytes and spermatozoids. For instance, it has been shown that males produce killer spermatozoids - able to kill spermatozoids from other males - and that these are produced especially when there may be suspicion of adulterous behaviour of females (for instance after long absence of the male). On the other hand, it appears that the female body can regulate which sperm of different partners is preferentially taken up, for instance by - subconscious - regulation of orgasmic experience [5].

In conclusion, the high social rank of a human male not necessarily confers absolute insurance for better reproductive success.

3.2.7. The development of language by natural selection is even more difficult to explain than other cultural characteristics like tool making

For language the problem for a natural selection explanation is even more difficult to overcome than it is for other cultural traits like tool making. Not only producers must be selected, but at the same time very different mutations - those mutations which enable understanding of what producers say - have to be selected gradually and naturally. We have previously pointed to the same bottleneck in the explanation of behavioural mate recognition systems [93] and this problem for language has been formulated also by Geschwind [31]. The arguments by Pinker & Bloom [66] to resolve this paradox, are far from convincing, and finally they have to rely on the Baldwin effect (see also Deacon [21]). It appears an odd supposition to state that better story-tellers will gain high social status, when one has to explain how 'better story understanding' genes have to be selected independently at the same time.

3.2.8. Summary

In summary, there is as yet no convincing evidence that language genes exist (see 3.2.2). Second, in cases where behaviours can be inherited by learning and mimicking, natural selection for individual genes can be a weaker selective force than group selection, whereby group selection favours all genes in a social group indifferently. Natural selection can explain the increase of general abilities: better vision, higher intelligence, better singing capacities. When it comes to explain how specific, directly observable and mimickable abilities - like speech and like making tools - can be selected, group selection becomes important enough to counteract or overwhelm natural selection, because new findings of individuals will be taken over by others, whatever their genes (see 3.2.3). For the same reason of mimickability, it is unlikely that mimickable behaviours will lead to higher social rank (3.2.4).

Third, trying to explain how language could be naturally selected by assuming that better speech entails a higher social status which in turn leads to reproductive success, can be criticized by showing that speech was (and is) only one of several factors in determining social status (see 3.2.5), and that it is uncertain that social status of humans is a guarantee for reproductive success (see 3.2.6). Fourth, it should be noticed that there is not really a link between being the 'leader' of a hunter-gatherer band and social status or reproductive success (see 3.2.5). The example of Symons [87], adopted by Pinker [67] on the reproductive success of tribal chiefs (often both gifted orators and highly polygynous) then is not really applicable to the humans which first developed language. Finally, it is difficult to see how natural selection for better speech could work, when realizing the difficulty of selection for better speech understanding to occur simultaneously (see 3.2.7).

3.3. Terrence W. Deacon: Did language and brain co-evolve, leading to both a larger brain and better speech capacities?

The hypothesis of Deacon [21] is well summarized by the following quote:

"Considering the incredible extent of vocal abilities in modern humans as compared to any other mammal, and the intimate relationship between syntax and speech, it should not surprise us that

vocal speech was in continual development for a significant fraction of human prehistory. The pace of evolutionary change would hardly suggest that such an unprecedented, well-integrated, and highly efficient medium could have arisen without a long exposure to the influence of natural selection. But if the use of speech is as much as 2 million years old, then it would have been evolving through most of its prehistory in the context of a somewhat limited vocal capacity. It is during this period that most predispositions for language processing would have arisen via Baldwinian evolution. This has very significant implications for the sorts of speech adaptation that are present in modern humans." (Page 358-359).

Here Deacon [21], like Pinker [67], relies on long term (2 million years) gradual evolution through selective advantage offered by the use of symbols, and he relies on Baldwinian evolution. It should be noted however that Deacon [21] clearly dismisses the notion of Universal Grammar [16, 17].

For the moment, it will suffice to say that we claim that our large brains did not expand to enable language and that language did not cause brain expansion. For example, microcephalics [77] and individuals with only half the brain of normal humans and so with brain masses within the upper limit of nonhuman primates - can learn normal speech [81]. It might help, but you do not need a large human brain to be able to speak. Furthermore, the archaeological evidence indicates a late origin for language [58]. For further comments on Deacon, see 6.2.

3.4. Conclusion

We have summarized some possible criticisms on the most renowned hypotheses on the origin of language and we have indicated why we have difficulties in accepting the existence of some kind of Chomskyan 'universal grammar' (except for some basic mental syntax which we share with animals (see 2.2.2)) and why a genetic explanation, adaptationist [67] or assimilative [21] seems implausible to us. There are several other criticisms possible [3, 82, and 89].

Still, this denial of a direct role of natural selection in the origin of speech and the arguments in favour of a cultural evolution process to understand the origin of language do not supply us with the concrete genetic preadaptations we need to understand how both production of symbolic sounds (vocal flexibility) and giving structural value to words in sentences (linguistic syntax) have been achieved.

We will try to answer the first question on vocal flexibility largely by evolutionary considerations about the phylogenetic origin of language (section 4), while the second question will be approached in an attempt to understand how infants acquire language (section 5). It is now finally time to readdress one of the most ancient explanations for the origin of language: our musicality or singing capacity, which is essential in explaining both the phylogenetic and developmental origin of language. Both the origin of language and its development in children, we argue, can be best understood by recognising that we are musical or singing primates in the first place.

4. Phylogenetic origins of spoken language

4.1. Protolanguages

Are there cues to protolanguage in close relatives of ours? Burling [13] states: "Since our surviving primate communication system remains sharply distinct from language, it is implausible that it could have served as the base from which language evolved. We are more likely to find hints about language origins by studying how primates use their minds than by studying how they communicate." The same conclusion was reached by Jonker [42]. This is not in contradiction with our claim for some universal mental syntax among higher animals (see 2.1.2).

However, we should mention that opinions differ:

"The analysis of the so-called long calls in chimpanzees and bonobos make it likely that the group-living great apes preserved the ability to create syntactically different calls, which would be developed by requirements of social life. A call repertoire emerged in these species which contained a large number of call variants at group level available for each group member via social learning. This type of animal call is different from ordinary animal communication; it shows some features of human language." [91].

There is also some controversy with regard to the speech capacities of our ancestors. Is speech already present in *H. erectus*? Since when can *H. sapiens* (which originated about half a million years ago) speak. Could *H. sapiens neanderthalensis* speak?

The archaeological evidence indicates that planning and other complex activities date back at the earliest perhaps 60,000 years ago. Noble and Davidson [63] argue that increasing tool use capacities, the occurrence of cultural artifacts (paintings, statues), and burial practices follow from the mental activity enabled by language. Such behavioural evidence of language starts with the Upper Paleolithic around 40,000 years ago. Maybe significantly, it was at this time that anatomically modern humans started to replace Neanderthals which only became extinct between 40,000 to 32,000 years ago. Others also argue in favour of a late origin of vocal language [58].

Here, we adopt the point of view that spoken, symbolic language is quite different from primate languages and that it originated only recently.

4.2. The musical primate

4.2.1. Humans have unique adaptations for singing.

The idea that the origin of speech lies in our ability to sing can be traced back to at least Jean Jacques Rousseau, in the seventeenth century [73]. It was suggested by the famous linguist Wilhelm von Humboldt in the nineteenth century [94] and by Otto Jespersen early in this one [41]. However, this approach to language has been ignored in more modern times. Indicative is that the word 'music' lacks in the index of the recent books of Pinker [67] and Deacon [21]. In

recent times, music has received serious attention by some linguists [48], but this was done within the Chomskyan paradigm and did not address the origin of language.

Just like song birds possess highly sophisticated syringes, there are very characteristic morphological changes of the human glottis and larynx, unequalled in any mammalian species [75]. Aitchison [1] remarks: "*Our language has more in common with the singing and calling of birds, than with the vocal signals of apes.*"

The resemblance to bird song was noticed already by Charles Darwin [19]:

"(Language) is certainly not a true instinct [Note 4], for every language has to be learnt. It differs, however, widely from all ordinary arts, for man has an instinctive tendency to speak, as we see in the babble of our young children; whilst no child has an instinctive tendency to brew, bake, or write. ... The sounds uttered by birds offer in several respects the nearest analogy to language, for all the members of the same species utter the same instinctive cries expressive of their emotions; and all the kinds which sing, exert their power instinctively; but the actual song, and even the call-notes, are learnt from their parents or foster-parents. These sounds, ..., are no more innate than language is in man."

Provine [68] has shown that a unique overlooked feature of human speech is our ability to integrate respiration and vocalisation. We, as humans, breathe in a way unique among the primates - since only we can neurally modulate sequences of tonal vocalisations upon our expirations. Other primates can vocalise but they are limited to only one vocalization per expiration. For example, both humans and chimpanzees laugh: however, chimpanzees do so by an `ah', `ah', `ah' sequence of repeated inspirations and expirations. In contrast, we do a modulating `ha, ha, ha...' or `ho, ho, ho ...' upon a single out-breath - this modulation often going on continuous for 16 laughter syllables [68, pp. 40-41]. Moreover, we can subtly tune our series of vocalisations upon a single continuous out-breath. Only amongst birds - not other primates - are there species that possess comparable respiratory-control ability. This underlies the curious fact that while some birds can imitate human speech, the much more closely related chimpanzee or any mammal cannot.

The neural control that allows song was, we suggest, a profound revolution: the `one breath one-vocalisation' rule stops chimpanzees not only from laughing like humans but also from being able to control the expiration needed to speak. This, as Provine [68] notes, is the reason why attempts to teach spoken language to chimpanzees have failed in spite of them being able to learn sign and token-based languages and even to understand spoken speech [76, p. 40-41].

Neural control of respiration allows many more kinds of vocalizations: over 700 vowels, diphthongs and consonantal phones were found in a sample based upon only one-twentieth of all the world's languages [52]. Moreover, such control allows the concatenation of very complex sequences. Thus, vocalisations upon a single out-breath combine into words, and these in turn combine into clauses, phrases and sentences. Neural control also allows modulations to be superimposed upon these vocalisations, such as intonation (linguistic, pragmatic and emotional), and this can be upon a wide variety of speech types like whisper, song, chant, scream, motherese, `Donald-Duck speech' and ventriloquism.

The tonal modulation of song is not only enabled by neural control but also by anatomical specialisation of the vocal tract for producing a wide variety of pitches and timbres. The peculiarity of our vocal tract is usually attributed to enabling speech, although it is sometimes also considered as a mere consequence of postural changes between the head and thorax that accompanied the upright stance and human-style bipedal locomotion (see also the postscript). However, the anatomical characteristics of the vocal tract are more closely linked to our capacity to sing than to our capacity to speak. People cannot sing without fully using all their vocal tract. However, people can speak without using large parts of the vocal tract (for instance in buccal speech, more familiarly known as Donald-Duck speech). Although normal speech contains a range of vowels and consonants that fully exploit the vocal tract, sufficient variety amongst the world's languages exists to suggest that intelligible speech only needs a subset of possibilities, exploiting only part of the vocal tract's pronunciation potential.

Without the neural control that enables song, speech could not exist. But which came first? We argue that we can speak because we can sing, and not that we can sing because we can speak, also for parsimonious reasons: the capacity to speak requires in addition to respirational control also syntax, phonology and the capacity to use and learn a vocabulary of words (see also the remarks in 3.2.7), while singing requires none of these (songs can exist without words). Second, in the development of speech by children, melody - in terms of interest in and production of intonation and rhythm - comes before other aspects such as phonology, syntax and vocabulary (see section 5).

4.2.2. Musical primates and song birds: examples of convergent evolution?

4.2.2.1. Introduction

The exact reason for the origin of singing behaviour is beyond the scope of this paper, but it is clear that the ability to sing has been naturally selected on many separate occasions - e.g. birds, whales and gibbons. Where this has happened, there have often been highly complex adaptations both anatomical and neural. The major idea here is that the complex changes which were necessary to develop an organ which eventually could be used for symbolic language production were selected for singing and not for speech. Convergent evolution to what may have happened to modern humans can be observed in song birds. Also song birds developed highly complex adaptations, anatomical and neural, as a result of natural selection for better song capacities [Note 5].

4.2.2.2. Music and mating

Song production and song preference play an important role in mating in song birds. Possibly music had a similar role originally in human mating - and it still has to some extent. Below are some of the several possible examples of the central role of music in courting behaviour. In several cultures males indeed bring serenades for their beloved. Also, male singers and musicians in general exert strong physical attractiveness on females (some females even have orgasmic experiences during concerts). Much poetry and love texts sound silly when proclaimed, but are quite acceptable and even touching and convincing when sung. Adolescents meet through singing, listening to music and dancing.

Moreover, sexual selection of the ability to sing is more plausible than sexual selection of the ability to speak. Sexual selection requires only an inherited preference for singers of distinctive emotional melodies rather than good story telling - something that requires that language itself is first well understood.

However, it might be objected that this fails to explain why females would also sing and speak. It should be noted that, while it is true that in many song birds only males sing, females inherit genetically the abilities to sing - something that can be shown since female singing can be triggered by hormonal treatment. Therefore, it is evolutionarily possible that a small genetic change triggered hormonal changes so that singing by females became possible, after it had first been sexually selected for in males. From considering some tropical song birds, we might understand how song capacity of females might have been selected for, eventually after it arose in males by sexual selection first.

4.2.2.3. Music and bonding

Indeed, the situation whereby male song birds exclusively sing happens to be true only for temperate regions. In some species of tropical song birds, females, as much as males, can engage in singing. Moreover, unlike in temperate areas, where male song links to the defense of territory and attracting potential mates, in these tropical species male and female singing links to bond formation and bond maintenance. This becomes apparent from the following quote [88]:

"In the tropics, although there are many species of birds the song of which is doubtless just as territorial in function as is usual in the temperate regions, the ornithologist is also struck by the number of examples where song appears much less aggressive in intent and where its function is apparently as a social signal, for maintaining pair and family bonds and as part of the sexual display, rather than a territorial one. Moreover, it is perhaps significant that most of the outstanding vocal imitators are found among tropical or subtropical species."

Thorpe & North [88] give the example of a pair of birds which communicated via a 15 note antiphonal duet. However when one bird died the survivor resumed the performance of the whole - something it had never done previously! They note of another case of duetting, reported elsewhere, that *'when the partners were absent, the remaining bird would use the sounds normally reserved for his partner, with the result that the partner would return as quickly as possible, as if called by name'*. This strongly suggests that we witness here a real case where song is used meaningfully in social communication as a bond. On top of that, the vocal tract of these birds has attained such sophistication, that it enables them to imitate human speech.

Music has bonding function in close relatives of ours as well. As noted above, male and female Siamang sing (the male bitonally and without melody; the female monotonously) to establish and maintain pair-bonding and the social recognition of their territory [38].

The cue of the use of song as a bond strengthening means of communication, rather than song being a trait which has evolved by sexual selection alone, itself leads to some intriguing remarks with regard to the special 'sociological' case humans are among primates (and animals/mammals in general). We know, by comparing the social nature of humans with other apes, that we too

have evolved an unique capacity to bond with each other. Indeed, it is also in the depth and complexity of our bonding that humans differ (apart from language) from other primates. From these observations and considerations we are tempted to conclude that musicality not only can explain how symbolic language evolved, but also that song, as a means to aid bond formation, can help to explain how the characteristic sexual-social relationships between humans became possible (see also 4.3.2).

4.3. Present and past social music

4.3.1. Various observations

What evidence exists for the key role of music in the lives of humans? Below we give a very limited excerpt of the functions and possibilities in human social life. All human cultures possess lullabies and use them to sing children to sleep. The music business is among the world's major industries. Going to war is so much more fun with a drum band marching along. Dancing to music can give people mystical trance experiences. Music brings up deep emotions such as hope, pleasure, comfort or sadness, and probably no other 'art' can do this as profoundly as music. From observations of currently existing 'premodern' societies, it is clear that music (and its counterpart, dance) must have played an even more important, pivotal role in early human societies. Music has a role, not only in rituals, but also in many practical activities. For instance, Australian aboriginals memorize the look of landscapes in songs. Although the music making of early humans has left no physical remains, it must have been a major part of their lives, as it still largely is an essential part of our lives.

4.3.2. Music and group identity

There is the observation that rituals, dance and song enhance group identity. With respect to territorial behaviour, it should be noticed that singing is indeed used for that purpose in close relatives of ours: "*In addition to the well-known territorial bird songs, some monkey species and all species of lesser apes have territorial songs.*" [91].

From what we know about ourselves as apes, increasing group identity could have put strong evolutionary pressure on singing behaviour. To understand this we must digress upon what has recently been found about our uniqueness as social apes. Humans, chimpanzees and presumably our earliest shared ancestors mix a life-style of belonging to a group, while separating into smaller parties during much of the lives. This is called an atomistic or fission-fusion social existence [72]. We, however, do so in a way that is unique because the bonds are robust and long-termed and allow for long periods of separation. Biological parents in all human societies form bonds with each other (though not necessarily monogamous ones). People form life-long attachments with friends and distant kin. We, moreover, usually form a life-long attachment with our 'identity group' from the level of our extended family to that of our nation and religion.

Early humans faced the paradoxical problem of relying for survival both on a group and on the recurrent need to split-up. Anthropologists and historians identify the mechanism by which people create and sustain the required social attachments with rituals and group activities involving synchronised song and dance [54]. The need for sustained social bonds may have

further selected (after possibly initial sexual selection and selection for stronger pair bonding (see 4.2.2.3)), for dance and song competence [Note 6].

Modern remnants of this ancient function of music might be the supporters' songs of sports teams, songs of any kind of club (e.g. students), war music and the national hymns, closely linked to the notions of territory and group identity. Indeed, music, singing and dancing still plays the central role in social life of all extant original bands. Ceremonies, rituals, and many other group activities (work-gangs, parties, festivals) all exploit the strong emotions which come with the ensemble of vocalisations and movement. Just think of the emotional bonding, the sense of belonging, the experience of 'together we are invincible' that accompanies marching songs, football stadium chants, National Anthems, camp-fire songs, hymns, corals, etc.

Increasing group identity exists in a nonmusical form in the collective intoning and synchronisation of bodily movements in religious prayers, petitions, supplications, orisons and worship. In modern societies, such synchronisation offers people a temporary sense of belongingness. In most cultures, they form an important part of rituals, ceremonies and other shared enjoyments which result in the affective togetherness that creates and sustains a society's collective existence [10, 54, 78].

4.4. Conclusion

Whatever the role of early singing was (territorial marking, courting, pair bond maintenance, enhancing group identity) it is clear that singing, musicality and dance had an important role to play in human social interactions, and that consequently musicality is plausibly selected for by good old natural selection. The development of a complex organ like the *Homo sapiens* vocal tract then can be understood to have been developed by natural selection more easily than in case we have to hypothesize that this natural selection occurred on the basis for selection of better speech [21, 67]. Only later on, these vocal abilities were used for speaking, and this view coincides with the proposition of Gould & Lewontin [34] that language is a spandrel or an exaptation: language was possible because of a preadaptation which developed for other reasons. While singing is an innate capacity, an instinct, speaking is a possibility emerging from singing and increased mental representational capacities. We could better speak of the song instinct than of the language instinct.

Comparing the role of song in some tropical song birds and in the siamang, one is tempted to state that song co-evolved with pair bonding, and thereby also helps to explain how the intriguing social and sexual characteristics of human life evolved.

5. Melody and language learning by children

5.1. Introduction: the semantics of spoken syntax

Do humans have a language acquiring device as Chomsky has proposed?

Most students of language easily accept that semantics is about linking mental representations of objects and concepts to the symbolic lexicon that happens to be used by a language. However,

when it comes to syntax, most linguists seem to assume that there is only linguistic syntax. Above we have argued that all higher animals possess some universal mental, thinking syntax (see 2.2.2), while on the other hand it is tremendously difficult to discover any universality among the amazing diversity of spoken syntaxes (see 3.1).

The problem with spoken syntax therefore boils down to the same problem of linking lexicon to mental representation: semantic meaning must be given to spoken syntactic entities by linking them to the mental syntax. We think this approach has been overlooked by most students of language. Then one must wonder how this can be achieved, since spoken syntax can be any kind, while mental syntax can be supposed to be largely alike among humans - and basically even among higher animals.

5.2. Music and language development

One of the big mysteries in speech acquisition is how children identify words. While the words on this page are divided by spaces, spoken words are not. Before you can identify words you have somehow to identify where and when they start and end. Failure to solve this hard problem holds back artificial speech recognition. The earliest voice recognition programs required that people spoke words slowly and in isolation. We suggest, backed up by a growing research, that infants solve this problem by listening to the rhythmicity and to the melody of stresses and tones in speech.

Even before children are born, their brains are familiar with the sounds that will surround them after birth. Newborns prefer the voice of their mother over that of strangers [23]. If a mother repeats a short story twice a day for the last six and half weeks of her pregnancy, her newborn child will prefer hearing it to one she did not [24]. The womb is an acoustic filter that preserves the intonations of a mother's speech. Thus, the brain is learning to hear speech as a melody from long before birth.

This is supported by other work upon newborns. It has been shown that newborns can discriminate the rhythm of multisyllabic stressed words suggesting they are already sensitive to the word-rhythm [74]. Moreover, newborns already prefer infant-directed prosody stressing speech (motherese) over adult-directed speech [18]. Complementary to this, mothers expand the intonation contours of their speech to their child as soon as it is born [28]. Such motherese compared to adult-directed speech has emphasized prosody, namely higher overall pitch, wider pitch excursions, broader pitch range, increased rhythmicity, slower tempo, longer word durations and increased amplitude. Newborns moreover can distinguish their own language from a foreign one, something which must be due to the unique, prosodic cues of a language [55]. This suggests they are increasingly able to focus upon the unique intonation aspects of their 'mother' tongue.

Children's own vocalisations, it should be noted, also start to be affected by these intonations:

"A cross-cultural investigation of the influence of target-language in babbling was carried out. 1047 vowels produced by twenty 10-month-old infants from Parisian French, London English, Hong Kong Cantonese and Algiers Arabic language backgrounds were recorded in the cities of

origin and spectrally analysed. ... Statistical analyses provide evidence of differences between infants across language backgrounds. These differences parallel those found in adult speech in the corresponding languages." [22].

There is also the observation of the tremendous similarity of pronunciation within a slang. We all know the phenomenon that one can easily recognize the region where one comes from. Many people never succeed in speaking properly the standard language because of an ineradicable accent, which indicates the thorough imprinting which occurs: we do not only acquire lexicon, we mimic intonation almost exactly from our environment [Note 7].

The previous paragraphs lead us to suggest that some auditory equivalents to Rizzolatti-cells (see Note 1) must exist. Rizzolatti-cells and equivalents may be an important cue to understanding mimicking, to link the behaviour of genetically encoded cells to copyable observable (visual, auditory) behaviour of animals.

Intonation provides cues to how words are structured in sentences [59]. Words are not said uniformly but are intonation phrased. Spotting this intonation structure facilitates children to grasp how words are syntactically put together. Children use the intonational cues that tend to identify word beginnings [62]. These cues vary with language: stress for example in English, syllable in French and mora in Japanese. Children in all these languages develop a sensitivity to the intonational beat provided by these cues that mark off word separation.

Let us take a famous Chomskyan example which relates to inversion of the word order of statements in order to turn these into a question. Children with English speaking parents readily adopt that 'The man is here.' becomes a question by reversal of noun and verb: 'Is the man here?' But how does one turn the slightly more complex sentence: 'The man, who is tall, is here.' into a question? One might expect a child, who has just mastered the simple example to place the first 'is' in front of the sentence, to say: 'Is the man who tall is here?' But children never make this mistake. Do we need Chomskyan theory, borrowed from mathematics and logic? Linguists developed rather complicated theories (like X-bar theory) whereby humans use 'null' elements to cope with this and related problems (see Smith and Szathmary [83] for a brief explanation).

What if we adopted the answer that children simply hear which of the two verbs is the main verb. Say the complex sentence to yourself and listen how the intonation on the second 'is' is different from the first 'is'. Now, try to reverse intonations. It requires a little exercise to do so, since it is experienced as a very 'unnatural' (we should actually say 'uncultural') thing to do, which by itself provides circumstantial evidence on the importance and the strict use of intonation. Children just hear which verb is the one which goes along with the man, because of the intonation of the main verb. Remark that the pitch of the main verb in the complex sentence is exactly the same pitch the main verb carries in the simpler sentence AND in the question. Once this has been acquired, children can generalize this principle to any similar sentence they meet. The intonation recognition capacity is one which stems from our innate musicality (naturally selected recently for other reasons than language itself), while the generalization capacity is part of the mental syntax capacity which we have inherited from animals (naturally selected for still other reasons). Bringing the two together one can have something like syntactic symbolic language.

Thus, children start off experiencing language as a kind of music. Parents and others respond to this sensitivity by making their language to them more musical - motherese. The rhythms of speech, which are heightened by motherese, provide the child with a means to use their sense of rhythm to spot the words and sentence structure. Memetic ontology thus replicates memetic phylogeny. In other words: music is both the answer to the phylogenetic and to the developmental origin of language.

Children, before acquiring the language spoken around them can distinguish phonetic categories of foreign languages they have not heard [27, 86, 90], only to lose this ability at around ten months [4]. One wonders why children should have this ability, in case language was naturally selected for, since this would require only the evolution of recognition of a limited phonological set. While explaining this from a 'natural selection for language' point of view is a real conundrum, it becomes triviality when adopting an innate sensitivity for melodizing.

Also, there are the numerous reports on the application of Music Intonation Therapy [2] to treat language disorders, as is exemplified by the quotes below:

"In order to develop a useful communication system, a 3-year-old, non-verbal autistic boy was treated for 1 year with a Simultaneous Communication method involving signed and verbal language. As this procedure proved not useful in this case, an adaptation of Melodic Intonation Therapy (signing plus an intoned rather than spoken verbal stimulus) was tried. With this experimental language treatment, the patient produced trained, imitative and, finally, spontaneous intoned verbalizations which generalized to a variety of situations." [56]

"We examined mechanisms of recovery from aphasia in seven nonfluent aphasic patients, who were successfully treated with melodic intonation therapy (MIT) after a lengthy absence of spontaneous recovery." [7].

"In patients with brain lesion, a pre-verbal, emotionally-focused tonal language almost invariably is capable of reaching the still healthy sections of the person. Hence, it is possible for music therapy to both establish contact with the seemingly non-responsive patient and re-stimulate the person's fundamental communication competencies and experience at the emotional, social and cognitive levels." [43].

Furthermore, it has been shown that music is not only important for developing linguistic skills, but also serves as a memory aid [65] and plays a role in the development of motoric skills [12]. Strong suggestions for the existence of a music acquiring device comparable to the hypothetical Chomskyan language acquiring device have been made by others. We claim that this MAD is our LAD:

"Full-term infants' performance in detection of melodic alterations appeared to be influenced by perceptual experience from 6 months to 1 year of age, and an experiment with infants born prematurely supported the hypothesis that experience affects music processing in infancy. These findings suggest parallel developmental tendencies in the perception of music and speech that may reflect general acquisition of perceptual abilities for processing of complex auditory patterns." [51].

"This indicates the existence of a partly innate and partly acquired competence to judge what is acceptable and what is not, within the tradition of Western popular or classical music. This seems to indicate the existence of some deep structure of tonality, comparable with Chomsky's deep language structure. Asians who have not been much exposed to this kind of music find the task very difficult." (Kalmus & Fry [44], reporting on experiments whereby subjects were asked to evaluate some characteristics of Western classic music).

The last sentence from the previous quote is again a strong indication for the importance of the tonality of the language and the music of a child's culture in molding its innate recognition capacities. Depending on the culture, one's experience of what sounds acceptable and what is not, is completely different (by itself again an indication against a universal spoken grammar and natural selection of language). This is nicely illustrated by the fact that (Western) MIT therapy has to be adopted when it is used in an Asian country. When applying MIT for use with Japanese patients, the authors report that basic changes were necessary, because of the completely different 'pitch' of Japanese language [79].

Furthermore, Simmons & Baltaxe [80], studying adolescent autistics with linguistic impairments, suggested that:

"... Perception of prosodic features may be crucial for decoding and encoding linguistic signals. Autistic children may be lacking in this ability."

6. Final conclusions

6.1. Summary

We argue that a combined genetic and memetic explanation is needed to understand what language is about and how it developed originally and develops with almost every new human. According to the point of view presented here, symbolic, spoken language emerges from the (coincidental) combination of complex representational capacity with intonation recognition/reproduction capacity (which itself develops in close connection with singing capacity). As such, it is claimed that it is not language itself which has been naturally selected for. Language is considered as a cultural phenomenon very well comparable to bird song culture, only more sophisticated (variable, flexible, more symbolic, syntactic) just because of the more sophisticated mental representation capacities of higher apes. In summary, birds did not develop symbolic language to the extent that humans did, because of more limited mental representation capacities, chimpanzees did not because of lack of singing capacities. Humans simply happened to combine both characteristics. How language then can develop by memetic evolution, might partially be answered by work presently being done with interacting robot agents [84], and is the subject of further work [82].

Once the preference for sound variety has been selected for, something which may happen for various reasons and which has occurred independently in different animal taxa, individuals which can produce any kind of primitive song may be reproductively more successful through sexual selection. Moreover, the group of singing and dancing individuals as a whole, whatever the genetic make-up of the individuals, may become more successful because of the increased

group identity awareness which makes its members cooperate more efficiently or which may make the members lose their individuality to some degree, resulting e.g. in more fierce, aggressive behaviour with regard to non tribe members. Indeed, another typical characteristic of humans is our long tradition of warfare and genocide [25].

6.2. How does this approach compare to the hypotheses put forward by Chomsky [16, 17], Pinker [67] and Deacon [21]?

With respect to the development of language in children, one can agree with Chomsky that humans have special abilities to adopt language and syntax very spontaneously early in childhood and this can be called an innate language acquiring device. Still, it probably might best be understood as an innate music acquiring device, which enables to link any possible syntax of spoken language - the one used by the adults which happen to raise the child or by other children which happen to grow up with the child - to the universal mental syntax, of which we share the general basic possibilities for categorization and for generalization of causal rules with animals.

We do not agree with the Chomskyan suggestion, taken for granted by Pinker [67], but thoroughly criticized by e.g. Allott [3], Deacon [21] and Tomasello [89], that there is such a thing as universal linguistic grammar.

Furthermore, the explanation of the origin of language in evolution and during individual development, as proposed here, has nothing in common with the adaptationist explanations of Pinker (see 3.2). Not only Allott [3] and Tomasello [89] point to different shortcomings of this kind of reasoning, but also Deacon [21] has clearly indicated several flaws. Several other criticisms are possible [82]. What Pinker [67] calls a 'boring conclusion', is simply a completely erroneous conclusion.

We can largely agree with Deacon [21] that we are a symbolic species, and his evolutionary reasoning is much more relevant than that of Pinker. However, Deacon [21], like Pinker [67], relies on long term (2 million years) gradual evolution through selective advantage offered by the use of symbols, while instead proposing Baldwinian evolution (evolution by genetic assimilation of behavioural characteristics).

Both our approach and - to a certain degree (because of the pivotal role of symbolic gestures and sounds) - that of Deacon could be called 'memetic'. The difference is that in Deacon's approach gestures and symbolic sounds come into play already 2 million years ago (at the stage of *Homo habilis*) and reshape the brain by genetic assimilation. In our approach natural selection for better general mental abilities and, only recently (possibly with the advent of *Homo sapiens sapiens*), natural selection for musicality explains the reshaping of the brain and the vocal tract and we claim that it is from the combination of increased intelligence and vocal flexibility that language emerges as a cultural process, while we dismiss natural selection or Baldwinian evolution guided by the advantages brought along by the linguistic capacity - as is proposed by either Pinker [67] or Deacon [21].

Once humans combined mental capacity and musicality, we rely on genetically encoded flexibility of the brain to explain how symbolic sounds - memes - could develop and restructure

brain mapping in a nongenetically inheritable manner. In other words, genes provide general capacities like brain flexibility, vocal dexterity, intonation recognition and reproduction capacity, while memes - through interaction with the developing brain - strongly influence the rewiring of the neuronal connections which make up a brain.

Although we date the influence of symbolic sounds much later than Deacon [21], we claim that once they originate, further changes occur in an almost purely memetic manner. The example below of the differences between literate and illiterate persons indicates how influential the means of communication are with respect to our mental abilities.

Our musical language origin theory coincides best with "the idea that removal of vocal limitations released untapped linguistic abilities which has been a major theme of a number of language origin theories (most notably argued by Philip Lieberman, in a number of influential books and articles)[49, 50]" (quote from Deacon [21], page 354). Deacon however considers this as an oversimplification and states that: "... *the development of skilled vocal ability was almost certainly a protracted process in hominid evolution, not a sudden shift.*" ([21], page 354), whereupon we disagree, backed up by the archeological record (see 4.1). Our hypothesis provides strong support for the insights of Lieberman [49, 50] (see also the postscript).

6.3. Why has the musical origin of language hypothesis been overlooked?

There is a further intriguing question, in case our hypothesis - which we will defend also on grounds of a more linguistic and neurolinguistic approach [82] -turns out to be a major key in understanding the origin of language. Indeed, one keeps wondering why this obvious, straightforward, and with hindsight even trivial approach to explaining the origin of language has been overlooked by linguists during the last decades. This is even more astounding, first because some of the earliest theories posed that musicality had to lay at the origin of language [19, 73, 94] - even Darwin [19] pointed to the resemblance and second because the importance of rhythm, intonation, melody, etc. in everyday life, in language therapy and in child language (as briefly reviewed above) is so overwhelming, and is well studied.

Several explanations can be thought of. First, there is of course the adaptationist paradigm which keeps us thinking in terms of function, usefulness, and which makes us overlook that usefulness is a post hoc consideration which can only serve as an explanation once the necessary events leading to the existence of some characteristics have taken place. Natural selection can explain why something still exists, but not how it came into being. The necessary variation is not a matter of natural selection, it is a matter of contingency, coincidence, mutation, recombination, symbiosis, evolution of characteristics for other reasons than the ones for which they eventually are useful now (preadaptation, exaptation).

Second, and closely linked to the previous considerations, there is the fact that we all are impressed by the explanatory power of natural selection of genetic characteristics in general, which makes us forget that natural selection is just a special case of selection (see Note 2). Therefore, there is a tradition of trying to explain everything with genes only.

Third, with respect to language, another important bias may exist. It appears that most linguists depart for their considerations from the present form of language, which needs a sophisticated grammar because much of communication is in the form of written code, which lacks the intonation characteristic of spoken language. E.g., writing down a joke may be experienced as an insult instead of as the tongue in cheek remark it was meant to be. In oral communication this will in most instances be clear, because of the facial expression and the intonation. Using written code, we need question marks, exclamation marks or ":-)" (the smile-sign as used in e-mail discussions) to indicate that what we write is meant as a question, an important remark or a joke. Written code, lacking intonation and eye-contact, compensates grammatically for the absence of a shared context with the listener, and finally influences more and more the way we speak, as becomes clear from studies comparing cognitive linguistic capacities between literates and illiterates.

Illiterates - when compared with literates of the same background - have been found to show cognitive difficulties in nonreading tasks such as phoneme awareness [8, 61], repeating nonwords (phoneme sequences that do not pronounce a familiar word) [60], memorising pairs of phonologically related words compared to semantically related ones, and difficulties in generating words which start with a common phoneme sound or which are the names of animals or furniture [69]. Several other studies lead to the suggestion that learning to read and write might not only challenge how people process oral language but also does change the organisation of people's brains [14, 95]. This was already suggested upon nonpsychological and nonneurological grounds [64].

However, most linguists start from the current situation (a literate world) and extrapolate and/or impose our way of thinking, living, interacting, communicating to the illiterate societies in which the original humans lived at the time language originated (see 3.2.5 for a comparable bias), thereby forgetting how different we are because of the completely different memes which populate our brains and because of the fact that the environment we have to cope with is incomparably different to the natural environments in which language first evolved.

6.4. Could large vocabularies alone be sufficient for the development of syntax?

It is important to quote here recent work of Bates & Goodman [6], which indicates that syntax abilities parallel very tightly vocabulary size over a wide variety of ages. Thus, though children may vary widely with respect to the size of the vocabulary at a certain age (some children acquire words more easily than others), the degree of grammatical competence they acquire is strictly linked to the lexical stage at which they are. This means that two children - one 3-year-old and one 5-year-old, but each with a vocabulary of 200 words, will have both the same stage of syntax.

Bates & Goodman [6] point out the implications of this for language in chimps. Chomskyans make it a slogan that 'animals cannot learn grammar' and hence that 'grammar is unique to the human species'. Bates points out, however, that chimps taught language in fact attain the level of syntactical competence you would expect from human children with the same size of vocabulary. Bates and Goodman [6] state that, if chimps lack syntax, it is not because they lack a human competence for syntax, but because their vocabularies are too limited.

This becomes apparent from the following quote:

"These differences between grammar and vocabulary are usually interpreted to reflect a qualitative difference in the language-learning abilities of non-human primates (that is, they have lexical abilities, but they lack a 'grammar acquisition device'). That may well be the case; after all, they are not human. However, the data that we have presented here suggest another interpretation: Because the animals studied to date apparently find it difficult to produce more than 200-300 words, symbols or signs, we should not be surprised to find that they also have very restricted abilities in expressive grammar. Consider the developmental relationship between grammar and vocabulary size that we have observed in human children. From these figures, it is clear that children with vocabularies under 300 words have very restricted grammatical abilities: some combinations, a few function words in the right places, the occasional bound morpheme, but little evidence for productive control over morphology or syntax. Viewed in this light, the difference between child and chimpanzee may lie not in the emergence of a separate grammar 'module', but in the absolute level that they are able to attain in either of these domains. Chimpanzees do not attain the 'critical mass' that is necessary for grammar in normal children; instead, they appear to be arrested at a point in lexical development when grammar is still at a very simple level in the human child. Hence, the putative dissociation between lexical and grammatical abilities in nonhuman primates may be an illusion".

From these considerations, it appears that to explain the rise of syntax, the problem is not how to explain any 'syntax' module arose peculiar to humans, but the problem is to explain why large vocabularies arose. If you can explain that, you can explain the rise of syntax. The solution to the problem of how a large vocabulary could arise, follows from what we suggest: humans are originally musical primates. Once humans gained the neurological abilities to control vocalisation needed to sing, they gained the abilities to create vast vocabularies of words. Although a large vocabulary on its own may be sufficient for syntactical ability to develop, as Bates & Goodman [6] suggest, we think that it helps when you have a MAD, a well developed intonation recognition/reproduction device, at your disposal. Musical ability may explain the rise of a large vocabulary and at the same time may be an extra gain to create and acquire linguistic grammar.

A 'musical origin of language' theory enables to bring together the ideas of Deacon [21], Lieberman [49, 50] and Bates & Goodman [6] (among many others). One could say that at some point, quantity (increased intelligence/mental syntax capacity, increased vocal flexibility, increased vocabulary) may change into (or emerge as) quality (linguistic syntactic ability). The basic difference between humans and animals then can be explained almost exclusively by the usage of symbolic/syntactic language. Of course, the explosive cultural evolution which became possible - once symbolic information processors like modern human brains arose - at first sight justifies the claim that at least one qualitative difference must distinguish humans from animals. It should be kept in mind that a minor additional trick sometimes can make a large difference. Moreover, one of us has previously briefly argued that the widely spread human need to claim human uniqueness can itself be explained from the need for continued self confirmation, which again follows from adding symbolic memes to the emotional - animal - being we are in the first place [92].

6.5. Musicality may also explain other typically human characteristics

Finally, it should be emphasized again that song as a powerful means for pair bonding, as it appears to function in some animal species, can very easily explain another intriguing and far reaching characteristic of (modern?) humans. Human musicality can explain how the typically strong human pair bonding could have evolved. As such, song could explain not only speech, but also could help to understand the typically sexual and social behaviour of humans.

Postscript

After this manuscript was accepted for publication, Lieberman [Lieberman, D.E. 1998. Sphenoid shortening and the evolution of modern human cranial shape. *Nature* 393: 158-162] argued to consider *Homo sapiens sapiens* (modern man) as a separate species from '*H. sapiens neanderthalensis*', because of clear facial differences with other hominids, incl. Neanderthals. Lieberman suggests that these changes may be related to the ability of speech. These considerations coincide with the claims - embraced in this article (see 4.1) - for a late origin of language, while the essential facial morphological characteristics of modern man may have been selected for by singing ability, enabling speech, but not for speech.

Notes

Note 1

In essence, the original memes (as used among animals) can be defined as behaviours which can be mimicked. Dawkins [20] referred to bird songs as memes. However, one reviewer remarked that only humans can imitate in an observable manner. If only this kind of conscious imitation counts for memes, than only humans produce memes and washing sweet potatoes by Japanese macaques (see 3.2.4) would not be caused by imitation and thus not be memetic. One may object that there is strong evidence for unconscious imitation underlying learning in animals, as becomes apparent from the work of Rizzolatti et al. [71]:

"In area F5 of monkey premotor cortex there are neurons that discharge both when the monkey performs an action and when he observes similar actions made by another monkey or by the experimenter. We report here some of the properties of these 'mirror' neurons and we propose that their activity 'represents' the observed action. We posit, then, that this motor representation is at the basis of the understanding of motor events."

Finally, it should be noted that conscious imitation itself might be a secondary consequence of the development of language, which makes possible reflexive awareness. If one could show that conscious imitation is a consequence of reflexive awareness (i.e., consciousness), this kind of imitation could be considered itself largely as explained once one has explained language.

Note 2

It is essential here to reflect on the definitions of selection and natural selection. Selection is a general principle: whenever there is variation on a theme, selection by the environment will occur, since none, one, more or all variations (configurations) may fit for existence in this environment. Natural selection is a special case which follows from the fact that selection takes place among variants on the theme of self-replicating systems, i.e. cells. The survival of the information processor (the cellular enzymatic machinery) is intrinsically linked to the information itself and vice versa. While differential survival of the information processors (the cells and the multicellular colonies) determines the reproductive success of the information molecules (the genes), the (genetic) information in turn determines the survival rate and reproductive success of the information replicators.

We could speak of a closed semantic circle (present in a metabolically open system).

However, in cultural-memetic selection, the information processors (animals, humans, copy machines, presses, computers) can die or stop functioning while the instantiations of information (memes, habits, knowledge) continue to flourish, and vice versa some instantiations of information can be lost or gained - for different reasons - without influencing the survival and/or activity of the information processors. As such, selection of behavioural/memetic/cultural information is basically different from the 'special case' of natural selection, although the general principles of evolution (change over time) and selection can be applied.

Note 3

Consider the following experiments:

A chimpanzee named Panzee first saw a keeper hide food in one of two locked boxes. When a second keeper entered, Panzee learned to point the second keeper in which of two cages the food was hidden in order to obtain the food. The next experiment however seems definite proof of the fact that the chimp knows which knowledge is in the mind of the attendants and which knowledge it should add to get the food: keeper 1 hides the food, locks the box and gives the key to keeper 2, while leaving. After keeper 1 left, keeper 2 hides the key and leaves. Keeper 1 then returns without knowing where the key is hidden. If the chimp had learned by trial and error alone, she would still point to the box where the food was hidden. Instead, on her first try, she pointed to where the key was hidden. The chimp showed she could fathom the working of another mind: she knew that keeper 1 did not know where the key was.
(After Mills [57])

Note 4

This leads to the remark that 'The Language Instinct' as the title of a book claiming a Darwinian approach to the problem of the nature and the origin of language, would have been disapproved by Darwin [19] himself.

Note 5

There might be some other resemblance between the song capacities of song birds and humans, although this is not really essential to the hypothesis put forward here. The front limbs in birds have been specially adapted for repetitive motor behaviour, flight, and Calvin [15] has proposed that special motoric capacities in humans, through e.g. natural selection for better throwing capacities, led to increased brain capacities in humans. Analogously, song birds are among the most intelligent birds. However, Calvin [15] and/or others seem to claim that these motor capacities by themselves are sufficient explanation for the linguistic capacities of humans, while it is argued here that these were only preadaptations which enabled singing, which itself then forms the essential preadaptation to speech. Thus, one could propose that for birds the flying capacity was a useful preadaptation for the possibility of song capacity, like for humans, specific motoric capacities - needed for e.g. throwing - prepared for the possibility of singing.

Note 6

We focus on song here, because the aim of this paper is linking it to speech. However it is clear that song and dance go together. Many societies are known not to distinguish song from dance [78]. In most circumstances where singing and dancing have not been professionalised and so are done by all members of a group, when people sing they dance (or make other collective bodily movements), and when they dance they sing. Dance does not require vocal control but it can be suggested that the processes which modulate vocalisation are not restricted purely to the vocal tract but extend to incorporate other aspects of the body. Indeed, research indicates a close linkage between speech and gestures [29]. We suggest that part of the evolution of vocal modulation included the ability to incorporate with vocalisation other patterns of movement.

Note 7

With respect to the 'environment', it should be noted in passing that children learn more readily from other children than from their parents and that they are more profoundly influenced by the habits (including language) of other children than by the habits of their parents (personal observations). A possible reason may be that they need to adopt the behaviours and habits of their play mates to get accepted in this social group.

THE REPLICATOR: A MISNOMER CONCEPTUAL IMPLICATIONS FOR GENETICS AND MEMETICS

By

Mario Vaneechoutte

Department of Clinical Chemistry, Microbiology & Immunology
Blok A, University Hospital, B 9000 Ghent, Belgium
E-mail: Mario.Vaneechoutte@rug.ac.be

Most evolutionary biologists and students of evolution in general have adopted the term 'replicator' for both genes and memes. There is indeed almost unanimous agreement [12]. However, current genes are not (self-) replicators and, as I will argue below, in contradiction to the current paradigm of the RNA-replicator world hypothesis, they have never been. Thus far, I came across only one source which defends a more correct interpretation of what genes are: "More pernicious, because less obvious, was the choice of the term 'replicator' for genes and other things of which copies are made. In English, the suffix -or is used to indicate that the root to which it is attached falls under the ontological category of an agent. As with the -er in 'copier', it means that which does the copying, not the sheet of paper that we copy when we feed it into a piece of office machinery. For the (passive) patient, in contradistinction of the (active) agent, we use other suffixes. In ordinary metaphysics we recognize that text gets created and modified by its author and editor, and transmitted by its copyist, perhaps using a copier. Had Dawkins [5] called his "replicators" "replicanda" his metaphysics would have been somewhat more transparent, but people might not have taken him so seriously". Quote from Ghiselin [8], in a criticism of the term replicator as it was coined by Richard Dawkins [5]. See also [9].

Indeed the suffix -or refers to an active agent, a processor. However, current DNA-genes are nothing but a material instantiation of information on how to make RNA and proteins, and perform no replication. Genes are replicated informational molecules, unable to replicate on their own, no more than enzymes can. Moreover, replication relies on the interaction of a whole collection of very different genes. Accordingly, 'memes' or bits of cultural information are processed, replicated and transmitted by human minds, photocopiers, presses, computer networks, etc. The original prebiotic genes are then better compared to plasmid genes which can be exchanged freely between different bacterial cells (processors) - OR with current memes (like printed scientific theories). They then can be regarded as elements of a language which enabled free recombination of different concepts, just like current scientific reasoning is possible because of the availability of copy true bits of information (printed matter), which can be recombined over and over again.

Partially due to the application of the term replicator for genes and memes, it has been overlooked that only the system cell as a whole enables self replication. It is important to emphasize that such a self replicating system thus far originated only once during the existence of Earth. Although it are the genes which carry heritable information, it is clear that daughter cells also need to inherit a minimal amount of processors, i.e. at least those enzymes which can transcribe and translate the DNA. So, although it are genes which are responsible for heritable information, it takes more than genes to be inherited to enable replication of genes, to make the processing system which can do so. Moreover, not only genes and some enzymatic processors,

but also membranes have to be inherited, since membranes are not synthesized de novo, but are synthesized only in close connection with the existing membrane. (This points to a very central and original role of membranes or to a 'membranes early' hypothesis of the origin of life.)

As a matter of fact, one could even consider new nucleotide strands as being a phenotypical artefact, since they are the product of enzymatic activity just as well as other cell components. Notice how this illustrates that the genotype-phenotype distinction itself has only limited usefulness, and - certainly at the cellular level - it occurs to be a somewhat artificial human-made dualistic distinction [see also 7], which in itself obstructs useful insights. One might object that for DNA-duplicates to be considered as phenotype, there is a difference with other phenotypic traits, namely that new DNA can be made only by using existing DNA as the mould. However, this observation accounts as well for membranes (see above). The only difference is the 'unlimited' [11] informational content of nucleotide molecules, but this characteristic is unlinked to replication.

I propose to adopt a terminology which is also used in information theory (and related fields like cybernetics)[see also 7] and to drop words like genotype, phenotype, replicator, interactor and vehicle, which have the disadvantage of poorly reflecting the dynamics and interactions which occur between biological processors and between biology and culture and which are in many cases strongly misleading. It is more revealing to speak of digital information processors (e.g. polymerase enzymes) and encoded, digital information (genes). In case of self-replicators, that is cells, both processors and digital information are embedded in a housing which consists of structural molecules (proteins, peptidoglycan, phospholipid bilayers, polysaccharides ...).

From these remarks, more useful definitions then can be put forward: living cells are the only self replicators on Earth. Enzymatic polymerases, resp. human brains, copiers, presses, etc. are all processors which can function as replicators of informational molecules, resp. informational symbols. These processors are information processors. Finally, informational molecules (polynucleotides) and texts, ideas, words, behaviours are replicable elements of instantiated information. For this category, we might adopt the term 'replicanda' as it has been proposed by Ghiselin [8], although the exact translation of this Latin term is 'that what has to be replicated'.

This definition then only holds for extant chromosomal genes, since indeed the cell is compelled to copy its genes in order to produce cellular offspring. However, it should be noticed that, certainly in the case of cultural information, the successful reproduction of information processors (like humans) does not depend upon the replication of cultural information, and therefore that there is no functional need to replicate this information.

'Replicata' or 'replicates' ('that what is/can be replicated') might be a more general term for informational molecules (nucleotidic genes) or cultural bits of information (memes) which are replicated.

In summary, the use of replicator for gene or meme is twice erroneous: they are not self-replicators (remark that 'replicator' is generally used to have the implicit meaning of self-replicator) and they even are not processor-replicators. Genes and memes are replicates or bits of replicable information. For memetics this means that we have to ask the question why some information is replicated more successfully by replicators like human minds and not why they

replicate more successfully than other memes. This more scientifically correct approach is e.g. used in the paper of Heylighen [10].

Selection, natural selection and cultural selection

These definitions of self-replicator, replicator and replicate lead us to considerations on the essence of natural selection as a special case of selection. Selection is rather a tautological principle: whenever there is variation on a theme, one of these themes will be best fitted to certain conditions, given by the environment, which also includes the other variations on the theme. Having different kinds of cars, one car will be best suited to reach high speeds on a straight road, one car will be best suited for riding a curly parcours, one car will be best suited for transporting many people, one car will be best suited for driving and parking easily in a crowded city, one car will confer an image of certainty and successfulness to its owner. In case most people live in cities and do not care too much about confirming their self image by means of the car they own, a type of small car that enables easy driving in the city will be sold most and will therefore be most successful when measured by number of copies made of it.

Specific cases of selection then can be understood by defining the theme, it's possible variations on the one hand and on the other hand the environment to which the different possible variations on the theme will have to fit.

All of these general considerations on what selection is hold as well for natural selection. However, natural selection is often erroneously considered as the only possible form of selection and it is forgotten that it is a very special case of selection, because the selection occurs among self-replicators (that is, cells), unlike cars, prebiotic metabolic cycles and ideas. Moreover, all the self-replicators stem from the first system able to duplicate. Since this duplication is not watertight copy proof, several variations on the original theme (the first cell or the theme of self-replication) are continuously produced, with as a 'welcome' side-effect that in most cases some of the variations will fit to whatever environment or whatever environmental change.

In summary, because a self-replicating system once occurred on Earth, it was possible that the original genetic code of it - which contained all the necessary information on how to make the next self-replicating system, was copied manifold. High copy fidelity, ensuring sufficient numbers of functional self-replicators, allowed also for a number of mutants to exist. Some mutants also could survive. Some mutants even could explore new environments or did better in the old environment than their parent wild types. A small percentage of erroneous descendants is an insurance for adapting to previously not inhabited environments or for adapting to the changing environment.

These considerations stem from an information centered approach which leads to more generally applicable insights than a gene centered one.

Natural selection is about the replication of informational molecules whereby the replication of the information depends on the functionality of the organisms, i.e. the genetic information processors for which the information encodes. The fitness of the phenotype is also the fitness of

the genes, and vice versa. Cells are metabolically open, but semantically closed systems. From this definition the difference with cultural information becomes obvious.

Just like variable genetic information and variable information in general, variants of cultural information are selected as well. I referred to this as a tautology.

For example, different scientific theories are weighed by the scientific community, where after finally one or still a third, or a recombination of still another five ideas appears to solve best the problems tackled and is replicated more successfully than other theories. The difference with natural selection is that the defenders of one theory - the scientists, the information processors - do not die because their theory dies or that they do not produce more offspring because they defended a successful theory. The information encoded in a meme (usually) has no influence on the survival of the processor (a human in this case). Vice versa, the ideas of a parent of many children are not necessarily - certainly no longer at present - successfully replicated ideas. Scientists with many children are not necessarily successful in spreading their theories. Christ had no children. The evolution of cultural information does not depend on the differential survival of its processors to proceed.

By reversing the adagium that memes must be replicators in analogy to the fact that genes are replicators into the statement that genes are replicates just like memes are, we can further suggest that genes were also replicates in prebiotic life. This suggestion contradicts the current paradigm that life evolved by competition between self-replicating RNA-molecules, whereby the cell gradually evolved around the fastest self-replicating RNA-molecules by means of natural selection, i.e. as a consequence of the differential reproduction rate of different self-replicating molecules. We propose to postpone natural selection till after the origin of the first chromosome containing cell (the first self-replicator) and to consider how a much more flexible and powerful kind of memetic evolution took place, comparable to what is happening since the origin of symbolic language in the animal world.

(It should be noticed that this does not mean that we have to dismiss the several exciting findings of RNA-research [e.g. 3, 14] nor that we disagree with the 'nucleotides earlier than complex proteins' hypothesis. Only, we propose to consider these findings from a different point of view.)

Symbolisation of information thus far has occurred twice on Earth. Prebiotic life developed a manner to encode information (symbolisation) into informational molecules (nucleotide strands). In biology, informational communication first took a nonchemical way of transmission with the advent of neuronal brains in animals which could make use of nonmaterial sound wave energy and photonic energy (vision) to transmit information (the origin of memes), where after strong symbolisation of this nonmaterially transmitted information has occurred in humans by the development of spoken language. This has finally led to the re-entry of material substrates which could carry information as visual symbols, in the form of written language. I will argue that the initial role of nucleotides is comparable to that of written language. While nucleotides enabled to encode chemical interaction, symbolic language enabled to encode behavioural interaction.

The essential thing about encoded information is that it can be mixed, recombined, merged, over and over again, because of the fact that it is not a metabolic process but a code on how to

perform such a process, which has the virtue that the information is not transformed (only transcribed or translated) during interaction. It is impossible to mix processes: One can't mix the activity of enzyme x with that of enzyme y, one can't take the bacterium *E. coli* and mix it with a piece of human tissue, while keeping a functional process; one can't mix the ideas of two people by mixing their brains.

But what if these processes also are encoded somewhere? Evolution has managed many times to combine the functions expressed in different modules of enzymes with each other. This could be done because there was a genetic code for it and by recombining parts of this code, something completely new, composed of already existing components but arranged in a different manner, could emerge. Similarly we can mix the eubacterium *Escherichia coli* with human enzymes, by inserting into its genome the code for such a human enzyme (e.g. for the production of insulin for diabetes patients).

We can mix different ideas since they can exist as a memory in our mind. This process is largely enhanced by the availability of written records, since this provides a more faithful, copy true back up. One can mix as many of these ideas as one can gather (e.g. by reading). Many different lineages of information can continuously come together. Sometimes (but apparently rarely) this leads to new useful insights. Furthermore, it takes only one processor and one template to make an unlimited number of copies of encoded information, something which is not achievable when dealing with processes.

The following is just a brief exercise of how we could envisage analogies between 'memetic' evolution towards the origin of the genetically encoded cell and present day cultural evolution (which may or may not lead to a novel kind of 'memetic' self replicator, e.g. some kind of self-assembling, duplicating robot as suggested by Tipler [13]).

Not in contradiction with some current thinking [e.g. 6] we assume the existence of a premetabolic network of interacting chemical molecules, organized in smaller networks of heterocatalytic cycles, mostly embraced by membranes. Such a membrane with its internal metabolic cycling can be called a protocell (which is devoid of genetic material), which interacted intensively with other protocells and/or free-'living' cycles and available molecules. The prebiotic system as a whole can then be compared with the current ecological network, which is composed of interacting genetically encoded organisms of different complexities.

The basic proposition of this paper is that symbolisation of chemical interaction (communication) between these protocells, and/or parts of their internal networks, is suggested to have been the original function of nucleotidic information. Instead of direct metabolic interactions (comparable to direct behavioural interaction between animals), some cells also started to make use of informational molecules, which not directly took part in the interactions but which nevertheless could influence the behaviour of other protocells (or of intracellular cycling), just like symbolic sounds or written texts can influence the behaviour of other humans (or of 'intrapersonal' thinking). (Remark that information was defined by Bateson as a difference which makes a difference to 'someone' else [7].)

Written/printed information, just like nucleotide information, can then be used without being transformed (i.e. analogously processed) during this interaction: it is digital.

With respect to the evolution of information, the chemical cycling within protocells is best compared to the animal body, performing metabolically essential functions. The membrane is best compared with the neural system (incl. brains and perception organs) of animals, since it performs interactive, communicative functions. Like some of these protocells started interacting by means of symbolic molecules (informational molecules, stretches of nucleotides), some animals (humans) started interacting by means of symbolized gestures and sounds. This leads to new interactions, also with nonsymbol using protocells (accordingly with other animals... bacteria). E.g., this symbolic information may have enabled the symbol using protocells to use metabolic energy from simpler protocells, like humans started to use animal power. This is to be regarded as some kind of symbiosis, since both symbol using and nonsymbol using protocells can have metabolic profit, like the number of horses increased correspondingly with the number of humans.

(Remark that an inadvertent outcome of this kind of reasoning is that this story is about symbiosis and mutual profits, in contradiction to the 'natural selection early' approach whereby the selfish fastest replicators won the game.)

While the informational molecules may have been internalized and processed at first in order to create new ones (like humans process words in an analogous manner: transformation), the interaction between protocells and informational molecules may have lead to the production of external processors (metabolic and informational enzymes). Similarly, humans aided by words have produced different external metabolic processors (wheels, ploughs, tractors, factories) and information processors (pens, type writers, presses, copiers, and computers).

Because in this model the replication of informational molecules presupposes only the ongoing of metabolic activity in general and thus not depend on the direct 'survival' of some particular protocell - unlike in e.g. models of molecular self-replicators and chemotons [11] and unlike present day chromosomal genes, both cases where the fate of the informational molecules is tightly linked to that of the metabolic efficiency of its cell - a lot of recombinatorial freedom was available to prebiotic chemistry. Similarly, cultural information can be recombined in an at random manner, whether or not this leads to silly ideas (like this one!?), because it is not linked to the fate of the replicators (human brains, computers). In fact the interaction between protocellular membranes, nucleotide encoded information and extracellular processors may have enabled to produce large extracellular heterogeneous protochromosomes, just like the interaction between humans and printed code and external information processors like presses and computers resulted in the production of scientific theories and complex machines.

The whole community of (simple protocells and) symbol using protocells became more and more dependent on the usage of external informational molecules and external informational and metabolic processors. The same happens in our present society, which would collapse at once when language, printed information, production machines or computers were taken away. In the end, most metabolic functions and most information processing were done by digitally processing external enzymes (e.g. polymerases), so that the role of the original protocells was

merely a motivating one. Accordingly, humans are less and less needed to keep the information processing going on. We put in a search string, push some buttons and the world wide web searches the relevant information. We are more and more needed only as motivators. Current co-enzymes (motivators of enzymatic activity) accordingly can be regarded as remnants of the original premetabolic protocells.

Finally, protocells consisted of a membrane, probably flattened since at this stage it contained only few internal chemical cycles, with an externally attached DNA-protocromosome - consisting of genes encoding for very different functions - and some externally attached enzymes and RNA-molecules. At several occasions such membranes may have 'gastrulated', whereby the chromosome and the enzymes and possibly some external medium with free enzymes and other molecules were internalized (in accordance with the obcell theory [1,2]). At one such occasion the enclosed informational molecules and processors contained all the necessary information and functionality to produce a self-replicating system (remark that reverse transcriptase was not enclosed). A similar event has not yet happened in culture (self-assembling robots [13] are just one imaginable outcome).

While explaining the origin of life as a memetic process, this approach also might provide a unifying theory for the evolution of information, whereby at two events symbolisation of information occurred - once of chemical interaction, once of behavioural interaction - and whereby at one occasion this encoding lead to a chemical self-replicator (the biological cell), a memetic evolution which seems to be happening again.

This symbiotic approach may circumvent many of the current problems like the 'chicken or egg' problem of DNA/RNA/protein interaction, not (yet) solved by the RNA-replicators world hypothesis. It also more easily explains how a chromosome consisting of very different functions, and whereby none of these genes by themselves contain sufficient information to cover the complex process of self-replication, can have originated. It circumvents Eigen's paradox whereby different self replicators outcompete each other when brought together in a cell, instead of merging into a chromosome (Eigen's paradox is solved (?) only by the rather artificial stochastic corrector model [11]). The much faster and flexible memetic (cultural) evolution also might resolve the time window problem (whether real or not [see 6], which lead some eminent biologists to adopt an extraterrestrial origin of life [4]. Of course, this 'memetic origin of life' hypothesis poses its own problems.

Abstract

This paper constructively diagnoses problems within the current merger & acquisition (M&A) theories and provides an alternative theory of corporate behaviour. We contend that humans are the hosts for a replicating entity known as 'memes'. Since finance based motivational studies on M&A activities have not established that this activity 'adds value' to the acquiring firm, it is our thesis that certain managers gain power through mergers and acquisitions. Thus, M&A from the point of view of the acquiring firm can be seen as driving the evolution of ideas, shaping the flow of technology, information, and tastes rather than as 'value adding'. In simple terms, managers (the meme holders) use mergers and acquisitions to enhance their power, and in gaining this power managers unconsciously provide an improved medium through which their memetic 'stories' may be replicated.

The paper first introduces popular theories surrounding M&As, the motivation for M&A is developed further in an examination of the need for managerial power, we then discuss how this power struggle relates to the 'battlefield' of corporate asset allocation allowing 'stories' to be told and replicated, and finally we ask questions and develop hypotheses that provide direction for future research.

1 Introduction

This paper co-integrates theories from several academic disciplines to explain the motives behind mergers and acquisitions (M&As). Financial theory and literature noticeably dominate the view of M&As presented in this article. This paper is not meant as a complete descriptive of all individual merger and acquisition motives, rather we attempt to explain certain motive phenomena that can be observed in an aggregate state. In a theoretical sense, when considering mergers and acquisitions finance theory suggests employment of a capital budgeting model. Correspondingly, the driver of all mergers and acquisitions should be to increase shareholder value, as the general consensus among those in the field of finance, is that the principal goal of a firm should be the maximisation of stockholder's wealth (Mandelker, 1974). However, we show that practitioners may not always follow such a theory and that there are often other important factors influencing corporate restructuring that are outside the realm of merely enhancing shareholder value.

Mergers and takeovers have attracted a great deal of attention from the financial press and other media in recent times (The terms merger and acquisition "*are used interchangeably to mean any transition that forms one economic unit from two or more previous ones*" (Lubatkin & Shrieves, 1986, p. 497)). Their characteristics and resulting values pre and post formation have been studied thoroughly in the financial literature (see Jensen and Ruback, 1983, for a review).

Theoretically, a company will enter into an acquisition or merger agreement if they believe that the NPV (company A + company B) > NPV (company A) + NPV (company B), where NPV is *Net Present Value*. Or simplistically, the economic value of these firms combined is greater than the economic value of these two firms as separate entities.

Financial theory implies that acquisitions and mergers occur in the hope of positive synergistical effects, with many managers citing synergy arguments in order to justify their actions (Friedman and Gibson, 1988; Maremont and Mitchell, 1988; Porter, 1987). Reasons for these effects have been offered, such as gaining fast access to new technologies or new markets, benefiting from economies of scale in research and/or production, tapping into sources of know how located outside the boundaries of the firm and finally monopoly type advantages. Lubatkin lists M&A motivation into seven main theoretical areas:

Monopoly Theory: Gaining market power

- Efficiency Theory: Operating synergies, financial synergies and management synergies.
- Valuation Theory: Bidder managers have better information about the target's financial performance than the stock market.
- Empire Building Theory: Planned and executed by managers who maximise their own utility instead of their shareholders value.
- Process Theory: Managers have only limited information and base decisions on imperfect information.
- Raider Theory: Managers creating wealth transfers from the stockholders of the companies they bid for.
- Disturbance Theory: Merger waves are caused by economic disturbances.

Lubatkin further adds that the most popular efficiency based theories are not substantiated empirically (Lubatkin, 1983), raising the question: Do mergers provide real benefits to acquiring firms?

The motivations for merger and acquisition activity seem logical and worthy of study as has been the case in the past (see Berkovitch and Narayanan, 1993, Markides & Oyon, 1998 & Trautwein, 1990). However, mergers may not lead to positive performance outcomes. The evidence to date suggests that most acquisitions cost more than they are worth and most mergers fail. Ravenscraft and Scherer (1987) and Herman and Lowenstein (1988), examine the earnings performance after takeovers and conclude that merged firms have no operating improvements. Porter (1987) found that more than half of the acquisitions by major US companies failed. Whilst Hunt states that "*most studies of acquisitions produce a success to failure rate (using accounting or finance or managerial assessments) of 50%*" (Hunt, 1990, p.70). Finally, Lorenz (1986) observed that takeovers are "*at best an each way bet*".

In Jensen and Ruback's 1983 review paper, they suggest that studies of the abnormal returns to takeover participants show that in general bidding firms seem to have no significant positive returns. Additionally, Loughran and Vijh (1997), Travlos (1987), Warnesly, Lane and Yang (1987), Franks, Harris, and Mayer (1988), Asquith, Bruner, and Mullins (1987), and Servaes (1991), find that acquirers paying with stock earn significantly negative abnormal returns. It is no surprise that this lacklustre performance in merger and acquisition returns has been summarised as unquestionably poor (Doz, 1988). In a 1970 paper that surveyed the findings of the finance research on mergers, Hogarty asked:

"What can fifty years of research tell us about the profitability of mergers? Undoubtedly the most significant results of this research have been that no one who has undertaken a major empirical study of mergers has concluded that mergers are profitable; i.e. in the sense that they are more profitable than alternative forms of investment." (Hogarty, 1970, p. 220).

McKinsey and Company revealed that 43% of a sample of international acquisitions failed to produce a financial return that met or exceeded the acquirer's cost of capital (Bleeke & Ernst, 1993). Non-financial studies show little improvement over Kitching's (1974) early finding that between 45% and 50% of acquisitions are considered failures or not worth repeating by the managements involved. Further support comes from Michael Porter's (1987) examination of the diversification record of large US firms over the period 1950-1986. He found that 53% of all acquisitions were subsequently divested, rising to 74% for unrelated acquisitions.

Therefore, if the discussed synergistical effects are present and financial capital budgeting techniques are utilised, why is it that bidder shareholders often never experience wealth increases? Correspondingly, in light of the historical evidence why do firms continue to undertake such seemingly inefficient capital investments?

Our aim (albeit a struggle) is to escape out of the constraining 'straight jacket' view that shareholder wealth maximisation places on the study of finance, to examine an alternative and perhaps radical foundation for the reasons behind many corporate mergers and acquisitions. It is proposed that mergers and acquisitions are both a medium through which managerial power is increased and a vehicle through which the 'corporate story' that we as consumers unconsciously absorb is skilfully replicated. The 'corporate story' represents an idea or combination of ideas that are transferred via hosts such as managers or employees within the corporate organisation. Theorists have examined this replicative dominance transfer of ideas, in which ideas that behave as competing, self-replicating entities are known as 'memes' (Dawkins, 1976).

According to Blackmore (1999) memes are basically ideas, *"they are much like genes or viruses in how they spread...we humans because of our powers of imitation have become the physical hosts needed for the ideas to get around."* (Blackmore, 1999, p.8). Memes (or alternatively the term 'ideas' may be used for ease of thinking) are synthesised from host to host (human brains) and by way of natural selection, evolution logically fabricates memes that 'survive' efficiently and spread widely through their human hosts. As Blackmore states *"evolution may appear to proceed in the interests of the individual or for the good of the species but in fact it is all driven by the competition between genes,"* (Blackmore, 1999, p.8). This view also holds for the study of memetics (the study of memes), for memes serve no greater purpose. In a sentence they are

selfish independent ideas operating only to get themselves copied (note that selfish does not refer to any sort of active human characteristic, rather it is used only to describe the isolated functioning of memetic replication). Blackmore states that "*the selfish replicators are transmitted and copied, and they do this as often as possible, so long as they have the machinery (human brains) and the building blocks they need for that copying.... In this way evolutionary design comes about*" (Blackmore, 1999, p.13).

Although memes were not termed or theorised until recent times, the notion of replication has been examined for many years. As early as 1896 Baldwin posited the idea of a new factor in evolution 'social hereditary' referring to the imitation in society (Baldwin, 1896). Further intrigued with this notion of imitation and instruction, Baldwin later implied that natural selection was not purely a law of biology but pertained to all the sciences, including the mind (Baldwin, 1903). The obvious question thus arises, what helps a meme make further duplications of itself or conversely what inhibits it?

It is our thesis that certain managers gain power through mergers and acquisitions, thus driving the evolution of ideas, shaping the flow of technology, information and tastes. In simple terms, managers (the meme holders) use mergers and acquisitions to enhance their power and in gaining this power managers unconsciously provide an improved medium through which their memetic 'stories' may be replicated (the term story refers to the managers vision or ideas of the future (memes), and the ideas they shape through their instruction upon people, products and services). The important notion in this theory is that managers are not, except by coincidence, acting so as to maximise shareholder wealth, but are attempting to gain power through acquiring more strategic resources, thus enabling story (meme) replication. Using an analogy from science, M&As can be seen as an agar plate through which stories are cultivated, easily replicated and ultimately imitated throughout human communities.

Having introduced the notion of memes it is not the intention of this paper to examine in depth the theoretical constructs built about the study of memetics, rather it is applied to suggest that there are alternative reasons that may be offered for human action and that managers have ideas (stories) and gain power whereby they are better able to express such ideas (creating replicative opportunities), with mergers and acquisitions used as an improved environment for replication. As Powell states, "*The stereotypical competitive market is the paradigm of individually self interested, non-cooperative, unconstrained social interaction.*" (Powel, 1990, p.302). As such markets (and more specifically mergers and acquisitions) have powerful incentive effects for they are the arena with which each party (managers in particular) can fulfil its own internally defined needs and goals, in doing so providing memes with an environment that is conducive for further replication.

This discussion is developed further following a three-prong approach; first looking at the need for managerial power as motivation for M&As; secondly how this power struggle relates to the 'battlefield' of corporate asset allocation, allowing 'stories' to be told and replicated; and thirdly we pose questions and develop hypotheses, which provide direction for future research to confirm our alternative view of M&A activity relative to memetic transference.

2 Power

Who holds the power in this community? Is it the politicians or the highly respected citizens or alternatively is it the managers who run the corporations, which hold the most assets, have large cash flows and employ the most resources? The notion of power has alarming implications for financial theory and its overriding objective of shareholder wealth maximisation. Organisational power is the main focus in this section, as organisational power is the type of power that is derived from an individual's position in the firm and the manipulation over important organisational resources. "*These organizational resources can be tangible, such as money, work assignments or office space, or more intangible, such as information or communication access to other people.*" (Riggio, 1996, p.375).

According to Mitchel, Agle and Wood, "*most common definitions of power, at least in part derive from the early Weberian idea*" (Mitchel, Agle and Wood, 1997, p. 865), that power is the probability that one actor within a social relationship would be in a position to carry out one's own will despite resistance (Weber, 1947). Pfeffer rephrases Dahl's (1957) definition of power as "*a relationship among social actors in which one social actor, A, can get another social actor, B, to do something that B would not have otherwise done.*" (Pfeffer, 1981, p. 3). Both Pfeffer and Weber acknowledge that power may be awkward to define, but it is not that arduous to recognise- it seems that it is the capacity of those who possess power to bring about the effect they desire.

Power orientated behaviour refers to individual actions aimed primarily at acquiring and using power and can be categorised into potential power and power (Kotter, 1979). Recognition of this behaviour is useful, as psychologists who have studied managers have said that power (potential or not) is relevant and important, because managers tend to have a high power motivation (Prince, 1972). Logically, the field of psychology dominates the power literature. Correspondingly, academics recognising the importance of power in the study of finance have made some attempts to integrate psychology literature with financial literature in their explanations of the financial marketplace. For example, theories such as 'Empire Building' (Lubatkin, 1983) have been assembled around the very notion of power and its corresponding effects. This corporate control theory of M&A motivation has arisen in order to account for possible shareholder/management goal deviations. According to this theory, mergers and acquisitions are planned and executed by managers who thereby maximise their own utility instead of their shareholders. Although seemingly understudied, the common thread in the 'Empire Building' theory, specifically the maximisation of manager's goals subject to constraints put upon them by the capital markets, is most supported in the literature.

Whilst "*such alternative merger and acquisition motives have received only modest attention*" (Trautwein, 1990, p. 189), Mueller states, "*there seems little doubt that the motives behind merger activity are not simply those that lie behind the more typical investment decisions, but are overlaid to a considerable extent by management attitudes and certain rationale that does not accord with our assumed over-riding management objective of shareholder wealth maximisation.*" (Mueller, 1970, p. 189). Newbold (1970) found that the reasons given by top managers for initiating merger motives did not explicitly include maximisation of shareholder wealth (Newbold, 1970), commenting and expanding on Newbold's report, Mueller (1970)

summarises by stating that, "*the reasons given by managers for merger and acquisition activity appear to be lacking in precision*" (Newbold, 1970, p. 197).

In terms of M&A activity, "*the heightened proclivity of larger firms to enter alliances has led some to conclude that the quest for market power may be an important consideration in such ties*" (Pate 1969, Berg and Friedman 1978). Hence, it is possible that many takeovers and mergers are built around the battle for internal power. They have a direct bearing on power struggles with the increased industrial might for the company translating into greater influence, prestige and pay for the executives. More importantly, M&A's are built around the battle for external power. By combining, corporations aim to enhance their market might, their innovative strength, their bargaining muscle and their ability to influence economic actors. To the extent that size is power, the merging and acquiring corporations have become more potent and the weakening of anti-monopoly intervention under open market focused politicians has opened the floodgates to a massive wave of activity in communications, financial services and drugs amongst others.

The theme still remains that managers regularly acquire and use power. They do so intentionally and wilfully, as well as instinctively and unconsciously. They exploit a variety of methods in this quest, some of which are well known, others of which are not. Indeed, so powerful have contemporary organisations and their managers become that economists such as Galbraith have overturned conventional economic theory about consumer sovereignty in brace of a revised sequence, with substantial corporations molding demand, fixing prices and planning production so as to subsume the market (Bell, 1975). In a summary of earlier studies concerned with the acquisition process, Power (1983) reported that the acquisition practice was not a comprehensively rational decision, suggesting problems such as suppressed uncertainty, lack of planning, political influences, varying process participants and no agreed upon acquisition criteria. Song (1988) gathered evidence that supports the assertion that senior executives' background plays a role.

"A successful manager, by the nature of his assignment as a manager, has access to considerable power over human beings in an economic sense, in an educational sense and also in a propaganda sense" (Mueller, 1979, p. 162). Thus, controlling managers usually succeed in securing compliance with their decisions simply because they possess the organisational power, which is obviously enhanced through further M&A activity. In interviews carried out by Kotter, he states that "*although no executive would admit it, at least publicly, they all spent considerable time in activities that were at least partially aimed at acquiring or attaining power for themselves*" (Kotter, 1979, p. 4) further adding that "*Managers were willing to admit privately that power dynamics were an important part of their work and that seemingly political behaviors are usually considered a way of life at the top levels of the organization.*" (Kotter, 1979, p. 385).

This of course does not mean that power is the only goal of managers, or that power is a fixed pie that businesses and individuals fight to divide, or that human interactions are reduced to a power nexus. Rather, it is merely to show that the efficiency based theories do not adequately explain corporate M&A behaviour, suggesting that it is power not reasoning that often drives the market and those in it. Extending this reasoning toward the influence of memetics we suggest that as managerial power increases, ideas that are transferred via such managers are ascribed

greater credibility. Therefore, where managerial power plays a substantial role in a merger or acquisition ideas are transferred through the manager into the new combined entity, such that their story is better able to be told. The interaction of ideas and managerial power may be illustrated if a correlation can be established between 'managers who have power' and the 'replication and sustainability of ideas or stories' for which they are agents (carriers). This issue shall be visited later in a discussion on how thought contagion is influenced by power.

3 Story

Who decides whose story is told? For instance, Blackmore asks, "*why do we have fax machines? Why Coca-Cola cans and wheelie bins? Why windows 98 and felt-tip pens. Because we want them is not a satisfactory answer because we need them is clearly untrue*" (Blackmore, 1999). In support of Gelb (1997), Williams (2000) reasons that the application of memetics and business offer potential explanations as to "*why some theories take off and come to dominate in our own culture for periods of time, perhaps even when there is a lack of empirical evidence to support them*" (Williams, 2000, pg. 273).

A further study, which brings together business and memetics, provides interesting insight into the area of market efficiency. Frank (1999) applies memetics to financial markets by asking the question "*Do markets evolve toward efficiency?*" Based on memetic theory Frank reasons, "*If there are many possible competing financial memes and only a small percentage of those memes are economically sound, chances are that the most psychologically appealing memes are not the most economically sound...*" (Frank, 1999, pg. 9). It would therefore make sense to rule out "economically sound" as a criterion for ideas or stories that are likely to be successful. Following from the previous section, it is our proposition that the stories seen in society are the ones told by people with the most power (replicative power- derived through organisational power).

Logically, memes that induce thought contagion behaviour in their carriers that tends to reduce rival memes will be fitter than those that do not provoke such behaviour (able to survive longer and replicate further), since they will have more resources for themselves. The distinct outcome being that a group of hosts with various memes will tend towards homogeneity resulting from the imposition of the stronger meme and elimination of all non-conforming memes (Boyd & Richerson, 1985). This notion has interesting connotations for the influential role of money in persuading individuals and groups to conform, as powerful companies (those with strong market positions) have the ability to coerce and initiate self-fulfilling prophecies. That is, if they say that something will happen then it often will, simply because of the power they possess. It is also directly applicable in corporate control situations where management teams compete for increased market power in order to dictate the flow of information and resources.

It has also been suggested that memes group together to aid survival. Such groupings of memes are referred to as 'meme-plexes' (Blackmore, 1998). This grouping of memes makes sense in terms of natural selection; if a story meme could group with a defence meme, it could decrease the chance of outside memetic attacks (i.e. the fight for limited space in the mind), thus enhancing its replicative ability. Perhaps this is why we see managers of possible target firms set in place popular anti-takeover strategies to help shield their story memes. 'Poison Pills', 'Lock-Up' strategies 'Pac Man' defences, 'Shark Repellent' defences, 'Sale of the Crown Jewels',

'Scorched Earth' Strategies and 'Supermajority' amendments are only a few of the prevalent anti-takeover defence mechanisms that have arisen in recent times. These anti-takeover defence strategies occur frequently in the business world, even though it has been proven extensively that on average target companies are paid a substantial premium and shareholders of these companies experience positive wealth gains when they are taken over, (Jensen and Ruback (1983), Loughran and Vijh (1997), Travlos (1987), Warnesly, Lane and Yang (1987)).

Power is a cultivator through which thought contagion breeds, evidenced by various ideas that spread through a society by those hold power, reverberating the notion of memetic transfer.

Remember that "*memes are ideas that propagate themselves around the world by jumping from brain to brain, memes are stored in human brains and passed on by imitation, individuals learn from society by imitation instruction. Ultimately, human life is permeated through and through with memes and their consequences*" (Blackmore, 1999, p. 6).

Historically religion has been used as an example of thought contagion (memetic transference), with large powerful groups creating different beliefs in god. In the past, religion that promoted large families were successful because they created more people to adopt the faith from their parents, this example draws resemblance for the memetic advantages of M&A activity, with religion and ceremonies very much likened to business ideas and practices, both of which are spread by one person copying another, creating large fellowship and belief.

As discussed, the way that we see and understand the world is guided by thought contagion (or the replication of memes). Certain characteristics enable thoughts or ideas to enhance their replicative ability. As stated by Dawkins (1976), the criterion for a successful replicator (successful in the sense that they create multiple duplicates) consists of three elements: Fidelity, Fecundity and Longevity. When examining mergers and acquisitions on this three-factor (fidelity fecundity and longevity) success scale, the theme remains that greater market strength places companies in a position where they are further able to supply the market with their ideas.

Logically, mergers and acquisitions allow this to happen as they have the enhanced power and distribution channels to make a vast number of exact copies (fidelity & fecundity), with the pooled research, design and marketing capabilities to defend against competitors and ensure continued expression (longevity).

The overall fitness of a meme can be determined by identifying whether it will maintain within an individual's memory and spread to other individuals or be eliminated. M&As illustrate the effect of this as they impose changes on business environments, overpowering the acquired companies and enhancing their story. De Jong (1999) illustrates how institutions act as filters for new concepts, which filters reflect dominant behavioural and conceptual practices. Concepts that survive organisational restructuring (M&As) may become institutionalised, forming part of the story being told.

When acquisitions and mergers occur the acquiring company is also able to increase its organisational networks, which aids replicative ability. As noted "*an organisation's power is determined less by its internal resources than by the set of resources it can mobilise through its*

contacts. The more such contact the firm has, the better it is 'plugged in' to the key task and influence process of the industry" (Galaskiewicz, 1979, p. 478).

Resulting from this, once those in power decide the direction of their environment, in general it is very tough for people to stop the flow and assume the 'old way' of life, (or if you like the replaced meme way of life). It is important to note that the competitive game here is not played at the level of the firm, but rather at the level of the idea itself. Victory in this 'game' means that the idea becomes adaptive (adaptive in the sense that the idea or meme creates a contagion type effect with a higher probability of 'survival' and 'reproduction').

In terms of managers replicating their meme driven stories (individual fitness) perhaps we should invoke the analogy of two people sitting on respective ends of the rope in a tug-o-war competition, each heaving like mad to serve their own selfish replication, with the stronger competitor eventually able to drag the weaker competitor: power creating compliance! Correspondingly, M&As are an excellent launch pad for memetic transference, for the power they build helps the propagation of ideas and the continual replicative muscling of such ideas.

Clarifying the relationship of thought contagion and power, M&A's are transactions in which organisational power is transferred, where the acquiring firm holds the power and in turn memetic transference sees that acquirer's story is replicated. In biological terms Mokyr states that, "*the environment into which seeds are sown is of course the main determinant of whether they will sprout*" (Mokyr, 1990, p.299). Whether or not comparisons between evolution and cultural or management progress are valuable has been the focus of a substantial and spirited debate in the literature, as Mokyr states "*the parallels are inevitably incomplete and do not provide the researcher with sharp analytical conclusions.*" (Mokyr, 1990, p. 275). Additionally, it must be noted that at present we cannot predict exactly how stories will evolve over time, we can only stand back and watch with a greater understanding as they unfold. We can however find deep, underlying reasons governing the unpredictable flow of such activity. Being at least in part, that those in power have the higher ability to dictate the flow of information and resources, ultimately shaping the products, services, systems and ideas that the economy maintains.

4 Future Direction

Our major assertion is that memetic transference is enhanced through M&As, where M&As are driven by managers need for power. Our stance however, has not come about through a clearly defined road map of empirical results. Rather, we have presented an alternative view of corporate restructuring, suggesting that M&As help to shape the evolution of ideas within society. In this final section we pose some key questions and present four hypotheses that provide direction for further research of this subject. Our intent is to offer a new thread of motivation toward understanding the complexities of behavioural finance.

Fundamental questions that one may naturally be compelled to ask are: Is it in fact managerial need for power that drives M&A or are memes themselves the drivers of such corporate activity? Contrastingly, do memes motivate managers to acquire power so that they can be replicated? Are memes indeed better replicated through M&As? If M&A's are driven by stories rather than the need for power, does the story being told have any relation to subsequent performance of the

newly combined corporate entity? Does industry classification offer any explanatory value in the replication and sustainability of stories that are told through M&A? Do M&As and their resultant stories refute our theories of memetic transfer by creating an entirely new story that cannot be explained by current logic?

Establishing quantifiable variables to test when addressing issues in behavioural finance is integral to producing acceptable conclusions. We propose the following testable hypotheses and offer reasoning as to how each one supports the framework of M&As and memetics.

Target firms replicate the ideas or stories of the acquiring firm.

In support of our discussion on power we reason that the dominance of the acquiring firm in a takeover transaction promotes replication of its stories and ideas. A finding in support of this assertion would suggest that M&As are an improved medium for memetic transference, where replication of the dominant entity's stories and ideas are enhanced.

M&A's with less debt in their capital structure provide a superior medium for memetic transference.

Given that there are agency concerns surrounding M&A, it has been posited that higher levels of debt augment management discipline, by keeping managers honest and focused on fulfilling their company debt obligations (Jensen, 1976, Jensen & Ruback, 1986). As debt requires servicing, it acts to constrain managers such that less debt creates greater management sovereignty, ultimately enabling managers to merge or acquire other firms and by doing so they improve the replicative chances of the memes that they hold.

M&A's with low managerial equity provide a superior medium for memetic transference.

Empirical evidence also supports the notion that managerial ownership acts to align managers' interests with the interests of shareholders (Shinn, 1999). Equity ownership serves to constrain managers against wealth destroying activity, which may take the form of an unsuccessful M&A. However, low equity ownership firms are more likely to experience higher agency costs such as managers seeking to gain power through M&As therefore providing memes with greater replicative opportunities.

Where executive compensation increases in relation to share price performance, stories told by such managers' display enhanced replicative ability.

Managers of firms that experience positive price performance are commonly rewarded with greater compensation in the form of bonuses, increased salaries, and more frequently stock options (Ofek and Yermack, 2000). Such executive compensation brings with it the credibility for the manager and his or her ideas. We reason that the credibility ascribed to the manager serves to enhance the propagation of stories and ideas for which the manager is an agent (carrier).

5 Conclusion

One of the most often asked questions in the M&A literature is why. Why do companies merge with and acquire other companies? From a strictly financial perspective, managers who make these investment decisions are meant to be undertaking wealth maximizing activity. However, the finance literature is replete with evidence that this activity only increases the wealth of the target shareholders. So what is in it for the acquiring firm? Why do the managers of these firms persist in this activity when it is not profitable?

Several theories have developed to explain this ongoing activity. Theories relating to efficiency and wealth enhancement have been largely discounted. Power based theories, on the other hand, have gained considerable support: Monopoly, empire building, and management entrenchment. But again, we must ask: Why?

Why is the power story so important? Why is it that managers are able to 'finesse' their shareholder wealth maximization responsibilities and instead seek power? We suggest that insight can be gained by an understanding of memetic transference. Memes and meme-plexes, which are successful, are those who replicate. M&A increases management power so that memes can spread more widely. Access to more resources provides memes with more chance to selfishly attempt to replicate themselves. When observed from this perspective, M&A activity appears to be an arena where power is not the end goal, but rather the means to the end. Memetic transference is the end goal.

Empirical testing of memetic transference is never easy. But the testing of several resulting hypothesis about M&A activity offers an opportunity to begin this process.

**A REVIEW OF: JASON POTTS (2000) THE NEW EVOLUTIONARY
MICROECONOMICS: COMPLEXITY, COMPETENCE, AND ADAPTIVE
BEHAVIOR**

Cheltenham: Edward Elgar, 2000 (ISBN 1 84064 543 1)

By

Jack J. Vromen

Department of Philosophy
Erasmus University, Rotterdam

Jason Potts's *New Evolutionary Microeconomics* is at once an ambitious and imaginative piece of work. It aims at providing a micro-economic foundation for all schools and traditions within heterodox economics. Anyone familiar with the 'family quarrels' within heterodox economics will immediately grasp that this is no small feat. To achieve his aim, Potts brings together various bits and pieces of notions, ideas, theories and models, dispersed over many different disciplines. Instead of letting his readers get lost in the bewildering complexities and perplexities of the various strands of literature that he draws on, Potts gently takes his readers by the hand and navigates them through the labyrinth. Potts is able to do this, because he found a key to connect all the strands. This key he calls the geometry of economic space. Instead of the orthodox Walrasian notion of an integral space (related to the mathematical notion of a field), in which all elements are connected to one another, Potts proposes a non-integral space as a unifying notion for heterodox economics. Adopting a non-integral space makes it possible to account both for particular interaction and for time irreversibility. Replacing an integral space by a non-integral space implies that the focus shifts from elements to the connections between elements. Accordingly, what primarily evolves in Potts's evolutionary microeconomics are connections between elements rather than the elements themselves.

This is an analysis at an extremely high level of abstraction, and Potts is aware of it. But already here, at this high level of abstraction, doubts begin to creep in. Orthodox economists often accused heterodox economists of not getting beyond putting forward the vague and unproductive notion that 'everything depends on everything'. And, indeed, many heterodox economists have strong leanings toward a holistic, non-reductionist type of approach. But if we are to believe Potts, then the accusation is more appropriately levelled against mainstream economists themselves. For the notion of integral space that Potts assigns to mainstream economics seems to imply the belief that every element is connected with all other elements in the field.

At a lower level of abstraction, I also found Potts's depiction of *hetero economics*, his own preferred notion of the micro-economic agent, questionable. Connections here are not defined interpersonally, but intrapersonally, as the cognitive technology an individual agent has at his disposal for combing his resources. Potts here explicitly invokes the image of Robinson Crusoe, an image that heterodox economists often have objected to. Only later on other individuals that the individual agent may interact with appear on the scene. Potts simply assumes that the logic by which agents decide whom to interact with is the same by which agents interact with the environment. This seems to run counter to how many heterodox economists view the relation between individual agents and social structure. These economists stress that the social environment in which agents are embedded affects the ways in which agents think, argue, behave

and interact with one another. This is taken to imply that the social environment needs to be taken into account right from the start. Potts pays no attention either to cultural evolution, to cultural transmission of memes (or similar units of cultural transmission) and to how this affects human behaviour. Once again this calls into doubt whether Potts really comes up with a microeconomics that is acceptable to heterodox economists of all stripes.

This does not diminish my admiration for the accessible way in which Potts introduces quite complex theories and notions, however, and especially for the comprehensive and creative way in which he links these theories and notions with one another. Graph theory, complexity theory, chaos theory, self-organisation theory and the notions of genetic algorithms and dynamic efficiency all get a succinct, but clear coverage. Without eschewing some elementary technical matters altogether, Potts succeeds remarkably well in showing in an informal way how these theories and notions can complement one another. Potts makes clear why he believes that the future lies in multi-agent computer simulations. All this is done in vivid prose. Potts's book demonstrates that complex and highly abstract notions and issues can be discussed in an engaging and entertaining way.

The only hesitation I have here is that sometimes it seems that Potts reads too much in mathematical formalisms. Potts sometimes argues as if each mathematical formalism has unique ontological implications. I think this is a bit naïve. Mathematical formalisms can be given many different interpretations. And sometimes the one mathematical formalism can be translated into another. For example, contrary to Potts's general point that the ontological implications of the mathematical notion of a field are altogether different from those of graph theory, it seems that a field can be described in terms of graph theory (as Potts himself acknowledges; see note 4, p. 81). Minor reservations as these notwithstanding, I warmly recommend Potts's book to anyone who is in for an intellectually adventurous attempt to synthesise various pioneering non-mainstream strands of theorising and modelling.

THE ECOLOGY OF INTENTIONS: HOW TO MAKE MEMES AND INFLUENCE PEOPLE: CULTUROLOGY

**By
Adam Westoby (1944-1994)**

**Foreword
By
Daniel C. Dennett, Director, Center for Cognitive Studies**

Whether the meme meme deserves to flourish depends in part on how well it can account for itself. Adam Westoby's "The Ecology of Intentions" makes a fine double contribution to this reflexive task, both as analysis and example. If you read it, you will see for yourself the variety of original and incisive ideas about memes that prompted me to become its willing vector. And if you read it, you will yourself provide another data point measuring the power of memes--whatever their intrinsic virtue--to spread by harnessing human minds to the task of their further replication. The draft before you is not just unfinished and unpublished; it is full of blemishes, gaps, half-baked ideas that distract us from the best ideas in it. Life is short, so why will you read it? Perhaps to see how Westoby's memes got as far as this (the Zahavi Principle at work in the memosphere).

These memes exited their nest through an extraordinary bottleneck: the relentless activity of a single unparalyzed finger on a word processor keyboard. That does not make them good ("for us"), but it does make them powerful; the task of getting them out dominated Adam Westoby's last years. Shortly after his death, his brother, Mark Westoby (some of whose own work in biology is briefly discussed by me in *Darwin's Dangerous Idea*, pp. 234-5), sent me the manuscript and the accompanying "brief background" account, with a request that I advise him about how to get his brother's work to the right minds. Some months later I found the time to look at this uninvited but curiously inviting package, and began to put in motion the process in which you are now participating. I considered undertaking the editorial task required to fit Westoby's manuscript for regular publication, but rejected it; the task was huge, and I had my own pile of projects to tend to. In the end, after sharing the manuscript with a few of my favorite advisors and informants on such topics--Richard Brodie, the late Ben Cullen, Aaron Lynch, Alex Rosenberg and Don Ross--and considering their advice, I offered to make the rough draft available as a Working Paper of the Center, which is the form in which you now see it, and in which it may be cited. Mark Westoby has provided me with further items about his brother and his work, which appear as appendices here. I never met Adam Westoby, nor have I met Mark yet, but some of their memes are now among mine, and I am pleased to have them on board.

The Center for Cognitive Studies has become something of an informal, self-selected depot for current work on memes, and I am sorry to say that I have been simply unable to filter, evaluate and transmit the material that has been sent to me so far. Piles of manuscripts lie as yet unread on my shelves--other authors should be warned of this--and Westoby's vehicle is the first that I now send on its way with this equivocal--but effective?--endorsement. I wish I had had the opportunity to discuss it with Adam Westoby, since I would have tried to adjust his vision of several of the philosophical topics he boldly tackles, and also would have asked him to expand

on the passages I found most suggestive and illuminating. But that is just a selfish reaction; every reader can execute one editorial function or another on this rich set of materials.

We at the Center would appreciate being informed of any discussions and commentaries of these ideas.

Brief background to the manuscript "Ecology of Intentions"

Mark Westoby
March 1995

The manuscript is of about 50,000 words and was written by my brother Adam Westoby. The current version dates to July 1994. Following that time, Adam's remission from myeloma ended and he died in November 1994. The July 1994 version represents a revision following comments he received on an earlier version, dated December 1993.

The manuscript takes the "meme" metaphor and applies it to a range of topics in cultural history, education and political economy. The metaphor is also developed beyond its usual form, notably by grafting "intentionality" on to it.

A brief outline of Adam's personal history may help to explain the mixture of ideas and knowledge he brought to the manuscript. In 1964 he went up to Balliol College Oxford, initially to read physics but switching within a month or two to Politics, Philosophy and Economics. He graduated with BA Hons I in 1967, and during 1967-8 did a one-year BPhil with a thesis on Haeckel's relation to Marx. By the mid-60's he was active in Trotskyist politics. Much of his time went on activism (newspaper sales, union organization etc) and on Marxist theory for some years. During this period the question of the nature of the State in the Soviet Union (also Cuba, China and the soviet satellites) was a key issue among Trotskyists. By the mid-70's he was no longer active in Trotskyist organizations (there had been a series of splits). His interest in the structure and political nature of these states continued, however, especially in the three major books of 1981, 1985 and 1989 (see short publications list below).

From 1970 he was appointed to a Lectureship in the Dept of Education of the Open University, a position he held for the remainder of his life. He developed readers and course materials in the sociology and economics of education.

In 1973 he was diagnosed with syringomyelia, a progressive spinal cord disability. He underwent a number of operations to slow its progress, but by the 80's he was spending much of his time in a wheelchair. From the late 70's on he lived with Sabitha Hasan, a lawyer (now judge) who had been disabled as a child by polio. They had two sons, born 1984 and 1987. During the 80's he was involved also with his father's progressive disability and eventual death (1988) from motor neuron disease. His experience of his young children, combined with his sharp-edged relationship with his own father, further shaped his thinking about the transmission of ideas. In 1989 he was diagnosed with multiple myeloma, contracted pneumonia while under chemotherapy, and was not expected to survive. He emerged alive, though much weakened, and in clinical depression during 1990-91. By this time he could move only in a powered wheelchair,

could sit up only for a few hours at a time, and could use a word processor only with one finger of his right hand.

During 1989-90 the whole face of Soviet-bloc politics had changed, and it had become impossible for him to recover his former expertise in this area. At different times from 1989 onwards I had conversations with him about memes (my own background is in evolutionary biology), extending first over many weeks in hospital, then days at a time at his home, interspersed with phone and email conversations from Australia. The manuscript "Ecology of Intentions" takes the metaphor of memes and applies it to a range of themes from Adam's continuing interests, including some large ones (the subjectivity of meaning; money and the social surplus).

THE ECOLOGY OF INTENTIONS: HOW TO MAKE MEMES AND INFLUENCE PEOPLE: CULTUROLOGY

Draft: please comment

By
Adam Westoby

fax 081-451 1641

Note to readers of this draft

Thank you for commenting. This note is to help you do so more effectively.

The date of this draft is printed above. It supersedes previous drafts.

Errors. Please point these out. Do not fear that your explanations will be too elementary.

Main text and footnotes. I hope to make the main text as readable as possible, consigning details, problems etc to the notes. Help in this regard will be especially welcome.

Footnotes. These are a miscellany of:

- References to sources, sometimes ill-remembered
- Notes and reminders to myself, and
- Short or unsatisfactory versions of what might go in the text.

Drafting/editing comments are placed in square brackets [thus]. They are mainly intended to be intelligible to me.

References/bibliography. This is very much a working version, both overgrown and incomplete.

Conversely, the fact that I have annotated an item does not imply that I have read all of it. Some items got there via book reviews etc.

In brief

This draft explores some ideas that see culture as organic.

Viewed as living things, cultures as a whole, and their parts, depend on at least two types of adaptation:

They must be adapted for inhabiting human psyches; and

They must survive the mortality of individual humans.

Culture must be adapted for direct or indirect transmission from living humans to other living humans; much of it is learned behaviour. It must be adapted, crudely speaking, for both parasitism and reproduction. Cultural objects must dwell within individual psyches, and they must pass between them.

Much of what follows is a sort of "natural history" of cultural objects, paying particular attention to these two features and the interplay between them.

I also have a practical - or, if you prefer, ethical - aim: to help us discuss what forms of culture we humans can most happily share our world with.

Phases and metamorphoses

Because cultural objects need both to get inside individual humans, and to pass between them, they exist (like carbon-based forms of life) as sequences of differentiated phases. This has some general consequences which it may be useful to sketch at the outset:

"Mental" phases, as experienced by human subjects, alternate with phases which have evolved to transmit well to, from and between subjects. We humans experience the contrast between mental and external phases as a gulf between subjective and objective. My discussion concentrates on evolution of the transmissible, objective phases of cultural objects.

Cultural forms arise - like embryos and organisms - by evolutionary accretion. Historically later forms are modifications of earlier structures, and actual structures embody the consequences of earlier development. The cultural forms experienced by present day humans incorporate long evolutionary histories.

This, in conjunction with the relatively fixed scale of individual humans (for example, our limited brain size and life span) imposes a cumulative process of abbreviation on cultural transmission. For example, modern school curricula must recapitulate in a few months developments that first took shape over thousands of years of cultural history.

This places a premium on forms of transmission which yield advantages in compression of this sort - such as, for example, extended symboling, reusable artefacts, or money.

Corresponding to "parasitism" and "reproduction" in cultural objects are two enigma-areas of the human sciences:

- the problem of meaning, or that of the subjective versus the public; and
- the problem of social reproduction.
- These problems are linked. Indeed I might recast them as follows:
- the problem of meaning may be approached as that of the separation out of persons, and the development of memory; and
- the problem of social reproduction is that of the cultural development of neophyte persons, or that of education.

Memes

I return to these problems in more detail later. However one approaches them, they are problems of complexity, of wholes being more than the sum of their parts. If I mention them now, it is only to introduce an "atomic" device which I think can help us make them a little more manageable: memes.

This derives not from physics but from biology. To begin with evolutionary biology analysed variation and natural selection among organisms. More recently its focus has shifted towards genes - the units of biological inheritance. Biologists remain divided on how best to think about relations between genes and organisms, and about how far life is naturally organised as organisms.

When questions analogous to these are transposed to human cultures they give rise to severe difficulties. I try to make progress by sidestepping them, at least initially. To do so I borrow a term invented by the biologist Richard Dawkins: memes, the units of cultural inheritance and selection.

What sorts of things are memes? Dawkins defined memes by analogy with genes. Just as, in biological reproduction, genes replicate themselves and "jump" from parent to offspring, surviving beyond the limited lifespan of individual organisms, so we may think of memes as a new form of life, leaping from mind to mind in human cultural transmission. Memes are "patterns of information that can thrive only in brains or the artificially manufactured products of brains - books, computers and so on". Memes replicate themselves (Dawkins holds) like genes: "by imitation ... in the broadest sense". They share certain fundamental characteristics with genes: "longevity, fecundity and copying-fidelity" (1976, 208). However, memes also vary, and the more successful variations proliferate. {Footnote 1}

Memes range from relatively slight - a few whistled notes of a popular tune - to great interconnected assemblages of memes. Such collaborating assemblages of memes are analogous, Dawkins argues, to the "survival machines" (that is, organisms) in which biological genes congregate to propagate themselves from generation to generation. We could, for example,

regard "an organized church, with its architecture, rituals, laws, music, art, and written tradition, as a co-adapted stable set of mutually-assisting memes" (Dawkins 1977, 212). I shall come back to the question how memes are incorporated in larger cultural objects. For the moment I ignore the distinction between simpler and more complex memes and treat them all interchangeably. The letter "i" is a meme; so is a paperback, a supermarket orange, a character in a film, a funeral, a screwdriver, a military command, a firework display, a quadratic equation, or a political party. Writers such as Daniel Dennett have pursued the idea that memes proliferate just because they are good at proliferating, not necessarily because human beings want them to. At first, Dennett concedes, we resist the idea of our brains "as a sort of dung heap in which the larvae of other people's ideas renew themselves, before sending out copies of themselves in an informational Diaspora". But this view captures an important truth. And it raises the question "Who's in charge, according to this vision, we or our memes?" As Dennett points out, there is no simple answer, and in his discussion the question leads (among other places) back to the enigma of the human self. (Dennett 1991, 202-3)

An advantage of the meme meme (as Dawkins rightly calls it) is that it gives us a relatively commonsense way of looking at problems of subject and object, personal and public, without collapsing one into the other. Thinking of memes as life forms which parasitise or domesticate humans helps avoid one-directional teleology. Memes make use of humans in senses just as real as those in which humans make use of artefacts and ideas. And it helps us to avoid humanist prejudices: by keeping memes conceptually separate from people, it allows us to examine some of their intrinsic characteristics, which cannot be reduced to those of human individuals.

My core argument is that the principles of cultural selection, as encapsulated in the notion of "memes" and their evolutionary interplay, may have much to offer the human sciences - a little as the principles of natural selection have increased the understanding of biologists. I discuss various ways in which memes affect people, in which people affect memes, and - particularly important - in which memes interact with each other in the larger ecology of memes.

Memes serve as my working answer to the question "What is a cultural object?" I know that there are powerful objections to thinking about cultures as collections of objects, and I do not mean to dismiss these. (Later on (Chapters) I look at some of the problems thrown up by a memetic view of human - and other - cultures.) I simply want to suggest:

- That such a view can illuminate some aspects of culture; and
- That some of its insights may help us to develop cultural forms with which we can more pleasantly share the world.

I take it as widely agreed that human culture is not yet so "user-friendly" as to be open to no improvement. I want to suggest ways in which we could helpfully think of this - as the problem of breeding better-domesticated memes.

By taking Dawkins' meme as a starting point I don't mean to dismiss its various near-synonyms and connected ideas. I discuss some of them ("culturegens", "brain bugs", "viruses of the mind" and the epidemiology of beliefs, etc) in Chapter X. One of the things I should like to do is

"evolve" (that is, vary and select from) the meme meme, to help it function and proliferate a little better. {Footnote 2}

Varieties of meme adaptation

"Tell me, how did you love my picture?" - Sam Goldwyn

What types of meme might we expect to be successful?

Let us look at some common meme adaptations, using the convenient shorthand of biological functionalism. What sorts of things might memes do if they "wanted" (and for our purposes they all do) to increase their success among the population of memes? More specifically, what sorts of things might memes do:

- In order to make better use of human beings, but also
- In order to succeed better in their interactions with other memes?

Memes' environments, after all, consist largely of other memes.

One - but only one - possible way is for a meme to adapt so as to be more palatable or more desired by more human beings more of the time. A very large number of human artefacts are of this sort.

Consider the orange laid out in neat peeled segments next to my keyboard. It is an outcome of combined genetic and memetic selection, and allows us to compare them.

What is chiefly interesting to me about my orange is its convenient packaging of pulp and juice, high in sugars and distinctively flavoured. I enjoy eating it; it refreshes my concentration; and it forms a healthy alternative to biscuits.

The orange however, began its career with quite different functions. Fruiting developed (starting about million years ago) as a secondary adaptation of the sexual reproduction of flowering plants. Natural selection acted in favour of variants which surrounded their seeds with tissues appetizing to animals. Two factors, in particular, acted through the foraging behaviour of animals to drive the evolutionary development of fruity organs around seeds:

- Better seed dispersion allowed offspring plants to populate the surrounding terrain more widely
- And proliferate better (for example by competing less intensely for light) improving seeds' chances of rooting by depositing them on the ground well mixed with animal excrement

Natural selection, however, explains only certain basics of my orange. It has also been greatly changed, in the last few moments of its evolutionary history, by cultural selection. The package of genes has become a meme.

In the few centuries that orange trees have been cultivated, humans have applied increasingly knowledgeable selection, driving evolution at an accelerated rate in pursuit of enhanced desirability to humans. The characteristics that have been modified or emphasised by human selection include:

- Colour: attractiveness to animals has been enhanced to attract consumers
- Sweetness and taste: quite different selective pressures have been applied to my eating orange than, for example, to oranges for marmalade or Cointreau
- Seedlessness: the original *raison d'être* of the orange's evolution has become an inconvenience. The very few seeds that may make it into my intestinal tract will pass on into an urban sewage system in which they have no hope of germinating.
- Uniformity: the varied shapes and sizes of fruit on wild orange trees have yielded to the astonishing similarity of Grade I eating oranges. This allows them to be shipped on carton with standard indentations, to be sold for a standard price, and to reduce the cost of distribution. The uniformity in the supermarket tray arises from cultural selection both between orange tree genes, and, at grading, between harvested fruit.

And, before the orange slides along the check-out counter to become mine, further cultural selection occurs, in which orange tree genes from round the world - Spain, Florida, Morocco and South Africa - compete to reproduce. They do so, however, not through excrement-smearred seeds, but through quite different memes - such as coins and balance sheets.

Derivative memes

Markets - with their continual revolutionising of both products and tastes - provide one modern, general forum of meme selection. In markets, money forms the institutional environment in which commodity-memes complement and compete with each other (through market research, product development etc, with their feedbacks on production and consumption). Comparisons between biology and commerce are now commonplace and terminology naturally exchanges: market research creates economic "niches"; superseded commodities become "extinct", etc.

Palatability or desirability to humans is not necessarily direct. In markets memes can be desired because they give access to other memes - for example, because they may be exchanged for them. If a type of meme emerges which can easily be exchanged for many other types, it can become desirable independently of any use of its own, emancipating its desirability, so to say, from particular desires. Money is such a meme, and the recomposition of desire as avarice, and the sense of the magical quality of money which humans now acquire in childhood, is one of the great accomplishments of memetic evolution. Intention becomes separated from all specific desires and all particular desirers; replicating its value, it passes, endlessly, from hand to hand. The emergence of money memes has had profound effects on the overall ecology of memes, forcing other memes to evolve effective symbioses with money, or face extinction.

(Some parenthetical questions: why do some variations of money succeed over others? Why does bad money drive out good? Essentially because simulating or diluting the currency are variations which shift the balance of probabilities as between the two things that holders of money may do with it: hold on to it, or spend it. The paradox is real partly because it is

apparent. {Footnote 3} One of the reasons why you can't take money with you when you die (if you try, it ceases to be money) may be that this destroys its exchangeability - put more generally, its intentionality. I return to the question of intentionality later. {Footnote 4}

The method of reproducible experiment in science can be viewed as another pervasive meme, in some ways like money. Very occasionally it gets subjected to analogous tests: Is it falsifiable? Or forgeable? Can it be replicated? It circulates tirelessly among expanding numbers of human individuals and institutions, insinuating itself into mental life wherever it can. Where it does it transforms our methods of thinking, and with it the practical world we create. {Footnote 5}

Why, then, does bad science not drive out good? Essentially because - like the spider's web, or the virus' sneeze {Footnote 6} - it has (to a degree) successfully imposed its own organisation of development, its own replicative history, on part of its environment, as "norms". Science's price for economic and intellectual freedom is - among other things - the capture or exclusion of other memes. Similar relations hold for other normalising memes, and their obverses: deviance, disability etc.)

In invoking money, or science, we also implied small galaxies of other memes (property/theft, ownership, contract, price, etc, in the first case; and reason/mysticism, evidence, law, order, etc, in the second). This is quite natural, as memes, like genes, go around in gangs. {Footnote 7} Indirect palatability can take other forms. Human beings also compete, and a meme's unpalatability to one person can be the basis of its desirability to another - rather as an insect repellent or an antibiotic is a meme designed to be objectionable or lethal to other species. An eviction order, like a bullet, is a type of meme which proliferates by making itself desirable to (some, but not all) human beings.

Certain memes, however, seem to be irreducibly unpalatable. Perhaps, as sociobiology occasionally seems to suggest, it is negative prescriptions - "Thou shalt not commit adultery" - which are most like this. This sort of meme has various options open to it to increase its circulation. It can link itself as tightly as possible ("Till death do us part") to other memes that *are* highly palatable - parental enjoyment, domestic bliss, home cooking, and so on. Marriage, incorporating and preserving its prohibitions and irritations, is such a meme-amalgam - analogous to the fruit that disperses many types of seed.

For some unpalatable memes, though, the pill simply won't carry enough sugar. At this point a meme's adaptation may need to work more interior changes. It may, for example, try to persuade carriers by distinctively human mechanisms: not that it would, on balance, be *pleasant* to ingest it, but that they *ought* to do so. Law, morality, political correctness and good taste are meme-ingredients of this sort. Various subsidiary means have developed to encourage these. Some appeal to human beings' wish simultaneously to conform to and maintain status within the group: socialisation, and its modern philosophical expression, universalisability. Others reinforce themselves with a moral carrot - eternal salvation - or with a stick conscience, hellfire, etc.

Yet linking a meme to its "should" need not be a grim business. Fashion, as much as morality, is fuelled by others and their expectations. Many delights of flirtation - and of social reproduction in general - are "frequency dependent" - accentuated by being generally relished: *Cosi fan tutti*.

{Footnote 8} And many memes proliferate by causing their human vehicles to internalise purposes beyond themselves and their kin: in a word, to embrace meaning in life. {Footnote 9} Considering meme adaptations will also lead me to ask - though not to resolve - some more opaque questions. Let me mention a few of them here:

Memes have numerous adaptations to their symbioses with humans. How have humans adapted to their memetic environments?

Why, even in solitude, do we feel shame, or joy, or laughter? What drives the evolution of our species' taste for meaning in life?

Why are we caught in the momenta of moods which seem to arise outside and despite ourselves?

Is the relative speed of meme evolution changing? In the past generations upon generations of our ancestors changed so gradually that it was imperceptible. Yet today teenagers inhabit a world unrecognizable to their parents. What has accelerated?

As this Cook's tour of culture suggests, Dawkins' meme meme promises (or threatens) to apply to a rich variety of cultural phenomena. It may indeed do this, but only by behaving as DNA-based life has done in colonising the biosphere - by evolving very diverse forms suitable for particular niches and problems.

Facets of memes: an overview

Like biologists, our task is thus to make some sort of preliminary classification of memes' features - only now slightly more detailed than the distinction between parasitism and reproduction with which I began. I have found it useful to distinguish 12 principal facets, to each of which the general principles of natural selection apply. What follows is, of course, intended as a shopping list, not as dogma.

Infectiousness. Unlike genes, memes can pass not only from parent to offspring, but between unrelated humans. They are like "infections" or "viruses" which proliferate by jumping from one human mind to the next. Good examples of this sort are fashions in dress, crazes that sweep school playgrounds or jokes that make the rounds. The crucial adaptations are transmissibility and memorability. {Footnote 10}

Teaming. For this characteristic it is no longer adequate to treat memes as leaping or infecting from individual humans to other individual human "atoms". The "meccano" aspect of memes links individual humans together in shared institutions and purposes. A football team is a good example of this aspect. This sort of meme links a number of individual humans together for common purposes. This happens through bonding mechanisms - a little as atoms link together to form molecules, and as certain types of molecules link to form macro-molecules capable of self replication.

Bonds. But there is a crucial difference. Human "atoms" link to each other via intentions and expectations. In football, each player wears a distinctive shirt to make clear which team he

belongs to. The shirt is a visible shorthand for his intentions - which goal he is trying to kick the ball into. In football teams and other memes of this sort individual humans act in concert by treating each other types of as tools or dolls - but as walking, talking, hoping, planning, feeling dolls.

Feelings (team spirit, in this case) are what allow human dolls to link to other dolls, and together manipulate the world. We do not need uniforms to recognise each others' feelings and act through them, but we do need some links. Uniforms depend on feelings at least as much as feelings depend on uniforms.

Immortality. This feature also subordinates individual humans to memes, but across time rather than space. Memes can endure across many human generations. A church provides a good example. So does a language or a state. So - to take more modest instances - does a song, or an accent. Rather as a candle flame, or an organism, can remain the same while most or all the atoms which make it up are changed, such memes endure historically through the replacement of the human atoms which compose them. A football team largely lacks this characteristic, since it is assembled for a period and for purposes shorter than the typical human life-span. But a football club has it - changing its players from season to season and its fans from generation to generation. For many people their football club, indeed, binds them more tightly than their church. I term this the immortality or eternal flame aspect of memes.

Memes within memes. Memes are constituted not just of "raw" humans, but also of other memes. Memes ingest, parasitise, inhabit, invade, include and conjugate with other memes. If we examine either the external or the internal environment - the anatomy - of a meme, much of what we see consists of other memes. (Though the distinction between inside and outside is an even more difficult one for memes than it is for organisms. {Footnote 11})

Values. Memes link humans by means of values as well as feelings. The members of the football team (and the club) are integrated by the common value they place on kicking the ball between the other side's goal posts - and, through and beyond that, on getting the particular vehicle for doing this nearer to the head of the league table. Values may also include commandments, rules, ideals, orderings and faded dreams. Change key values and you may destroy the meme. We can imagine a Martian studying our football match. S/he/it might easily draw the conclusion that if twenty-two grown persons wanted to propel a leather sphere as often as possible through a wooden hole, they should do so in concert. That would, however, be failing to see the memes for the people. Like memes, values derive from other values.

Meme vehicles. Successful memes persist across human generations by assembling into complexes which are capable of self-reproduction: societies and cultures. Societies are themselves memes, which incorporate other memes and memetically "inscribed" human beings and many other types of artifact. To endure, societies must reproduce values and feelings, as well as human beings. The meme vehicle, taken as a whole, must reproduce itself, including its atoms and bonds.

Selective extinction. Many of humankind's earlier cultures are extinct. This is not only because they originated a long time ago, but also because meme selection and evolution confer relative

advantage on (some) of the more elaborate variants. Similarly, the primitive nucleic acids through which life on earth first developed have long been displaced by more complex descendants - cells, organisms and species. The evolution of culture resembles that of life in that it confers advantages on (some) latecomers. Culture, like life, expresses combined and uneven development. {Footnote 12}

Scratchpad effect. A related point in studying memes, therefore, is that their evolution involves erasures and extinctions, as well as additions (new speciations). The cultural scratchpad incorporates traces of many vanished memes. As in biology, reconstructing history, much of which is invisible to our present eyes, is an essential part of understanding. History - change over time - greatly complicates classification, but it is essential to explanation.

Genotype/phenotype. Memes lack any single physical replication mechanism such as carbon-based life makes use of in the DNA helix. Consequently memes lack organic life's more clear-cut distinction between genotype and phenotype.

The "culturological principle". Any explanation or definition is itself a meme, with its own history and evolution. Earlier, less adapted, forms of biological explanation, for example, try to abstract from the problems of the new arising in time - but have, consequently, more limited success. Modern evolutionary biology arises from centuries of memetic evolution, from creation myths, through efforts of classification, to the recognition that no life form is final. The same principle applies to all memes, including all explanatory ones. I call this memetic principle the "culturological principle" (in allusion to the "cosmological principle" by which astrophysicists remind themselves never to assume that the Earth's position in the universe is a privileged one).

Humanism. Our view of memes is coloured by certain characteristic illusions or necessary appearances, analogous to creationism or vitalism in our thinking about organic life. One is the conviction that memes get their purposes from entities other than themselves, even from us. Another (in a sense the obverse) is that memes arise solely from other memes (or that values cannot derive from facts, or culture cannot derive from nature). It is possible - indeed common - for a human individual to entertain both these memes at once.

These features of memes are neither exhaustive nor exclusive. They do not, even together, define memes. And we cannot draw wholly watertight distinctions between them. For example the borderline between feelings and values is extremely fuzzy. I have nonetheless found it helpful, in trying to think about memes, to separate out these 13 points, and I refer back to them in the following chapters. This is why I have given them shorthand names.

Culture and psychology

"Culture is the passion for sweetness and light, and (what is more) the passion for making them prevail" - Matthew Arnold, Literature and Dogma

What sorts of problems might the meme meme help with? One, I think, is the apparent autonomy of culture.

The transmission of culture means, among other things, its passage from one human mind to another. A cultural trait is one that passes reasonably successfully, in recognizable form, from mind to mind, and is to that extent independent of particular minds and psychologies. A standpoint prominent in the human sciences at least since Marx and Durkheim is that of the autonomy - relative, or less so - of culture. It has been greatly encouraged by mass manufacture and mass education.

On this view the psyches of new born human infants are highly malleable - blank slates, or "general purpose" software - ready for the learning which their cultures of upbringing subsequently imprint upon them. A concomitant principle of this independence of cultural "software" from neuro-psychological "wetware" is an emphatic anti-psychologism, such as that which Durkheim expressed:

"The determining cause of a social fact should be sought among the social facts preceding it and not among the states of individual consciousness."

However, over the last few years ideas from human biology, in the form of "evolutionary psychology", have laid siege to views of human psyches as blank sheets of paper on which cultures autonomously evolve their messages. "Evolutionary psychologists" take aim at social science's assertion, or assumption, of cultural autonomy. They argue it is wrong to suppose that social and cultural regularities are all *sui generis*, not dependent on human beings' evolved biology. The life sciences are now starting to explain many important components of human psychology as adaptations of the hunter-gatherer life lived by human beings until the relatively recent evolutionary past (up to about 10-12,000 years ago, when agriculture began to take root in the Near East). Human beings' asymmetries of sexual preferences; our patterns of male jealousy and of female adultery; the propensity of young men to form aggressive coalitions for war; children's play fighting; attachment (and grief) between caregivers and children; our sex differences of spatial perception; our colour categories; our body language; our tastes for salt, sugar, fatty foods and open landscapes - all these (argue "evolutionary psychologists") may in principle be understood as universally human, "species typical" adaptations of hunter-gatherer life in a largely untouched nature. {Footnote 13}

The programme of "evolutionary psychology" raises problems of its own. {Footnote 14} Can we separate out genetically transmitted adaptations from culturally transmitted ones? Can we combine genetic and cultural transmission within a single ("co-evolutionary") framework? I discuss such problems below in the context of the sociobiologists' *bête noir*, the "Standard Social Science Model".

Cultural diversity and biodiversity

A related problem is that of cultural diversity. Nowadays our world is very different from the natural surroundings of our hunter-gatherer ancestors. Almost everything that urban humans see has been made or modified by other humans. Consider tangible artefacts alone. Many of these are mass-produced objects, but their variety of types rivals that generated by organic evolution. The contemporary individual, it is estimated, may encounter (and need to discriminate) 20-30,000 different specialised objects of common use during her or his lifetime (Petroski, 1993,

23). {Footnote 15} If our active vocabulary has greatly contracted, compared to our hunter-gatherer forbearers, with respect to living species (see, e.g., Levi-Strauss,), it has much expanded with respect to made objects. {Footnote 16} Indeed Basalla estimated that the number of distinguishable technical inventions now patented exceeds by a factor of two or three the number of different flora and fauna species identified by biologists.

How does technodiversity come to rival biodiversity? Knowledge of the basic machinery regulating evolution among genes has transformed biology. We now think in terms of the chemical mechanisms of genetic replication, of the discrete nature of inheritance, of the sources of variability and selection, of specialised reproductive organs and the isolation of germ lines, of speciation, sexual recombination, and kin selection. Such concepts are fundamental to our understanding of the diversity of life-forms based on DNA-RNA replication. And they form the groundwork which evolutionary psychologists bring to bear on humans' universal, "species-typical", psychological architecture.

The history of biological classification suggests some of the difficulties. Early classifications tended to distinguish species pragmatically - as, for example, in creation myths, or in "herbals" which grouped plants according to their medicinal uses. {Footnote 17} Only gradually did biological thought come to distinguish species in the modern manner (Aristotle, for example, did not always view them as reproductively separated) or to see their distinctive organs in terms of their functions for the organisms themselves. {Footnote 18} From there it was a further step to the Darwin-Wallace view of the evolution of species, and of the biological present as a "still" from a much longer historical film. Darwin developed his theory with almost nothing of our present systematic knowledge of inheritance {Footnote 19} or of the molecular patterns which transmit genes. And there remain arguments among biologists on the relative uses of classifications by adaptations, by evolutionary descent or by reproductive separation. {Footnote 20}

By placing memes at centre stage our understanding of culture can gain additional help from biology. Genes are difficult and arbitrary of definition, but that does not make them less real or less fundamental to our understanding of biological evolution. I suggest that we allow that memes are similarly difficult to define, but nonetheless treat them as real. Studying the natural history of memes and their selection may even help nature/nurture debates to yield more fruit.

Several approaches have already been developed, though they have attacked the matter from different angles and used a variety of terminologies. Population biologists have refocused their tools on learned or cultural traits ("memes" or "culturegens") and have developed formal models of the incidence and spread of learned behaviours in communicating populations of organisms. The transmission of learned behaviour has been studied in a variety of animal as well as human populations (Bonner 1980, Delius 1991). Models have been developed of cultural and genetic "co evolution" or "dual inheritance". {Footnote 21}

There is a conceptual difference between a form of learned behaviour as a cultural trait, replicated by transmission from human individual to human individual, and the part which the behaviour plays in the replicative cycles of a cultural complex. Singing *Silent Night* is behaviour learned by multitudes of small children; the song's collective rendition is a commonly-

encountered element in Christian congregations' rituals of winter renewal. The direct replication of memes from person to person is part - but only part - of the processes through which institutions persist across generations.

[WHAT is the meme, virus in this example?]

[Historical studies of technological and cultural change have often treated it as broadly analogous to histories of biological organisms. {Footnote 22} And crucial qualitative distinctions have been drawn between different *types* of meme, and the relationships between their evolutionary characteristics, and those of the humans who carry them. {Footnote 23} {Footnote 24}]

What sorts of phenomena might an evolutionary ecology of memes help us to understand?
Is the social superorganic: a meme's-eye view?

In my opinion the most interesting is the central conundrum in response to which ideas of the autonomy of culture have spread in the social sciences: the compulsiveness of the cultural and social. Cultural beliefs and practices have a variable and often arbitrary character. They combine this with their compelling, obligatory, "instinctive" action through and on individual human beings. "Our" institutions precede us and prevent us choosing. Students of society thus often posit the social as something independent of and - at least logically - prior to the individual, and reject ideas of already-formed human animals. Indeed many social scientists err in the opposite direction, conceptualizing the cultural and cultures as things developing independently of individuals, and reifying culture alone as the propellant of individual action. This is a view which, in its pure form, "evolutionary psychologists" regard as fantasy. {Footnote 25}

Suppose, however, we set aside for a moment our questions about how the social and cultural drive individual humans in the ways that they do. Let us also set aside our even larger questions about what memes essentially are, or if they really exist at all. Suppose, instead, we ask questions of the following types:

- What sorts of adaptations might memes incorporate in the course of evolution in order better to equip themselves to proliferate among individual humans?; and
- Why may this or that characteristic of a meme have been selected as an adaptation to its (then) environment?

These are two distinct questions, since much of the environment of many memes consists of other memes.

Rather than puzzling over the problem of how memes drive individual people, let us step back a little and concentrate on the distinct question: what drives meme evolution - the selection of traits to become more frequent *among memes*?

In borrowing such concepts as *adaptation*, together with connected ideas, such as *exaptation* from evolutionary biology I do not mean that they are easy of definition there. (An exaptation is, roughly speaking, an adaptation which, over subsequent evolutionary time, has assumed a

different function from that which initially gave rise to selection pressure in its favour. An example is the ear-bones of mammals, which began as the gill-structures of our remote aquatic ancestors. Exaptations are rather important among memes.) The idea of an adaptation is, however, so central to understanding why organisms (and memes) are as they are, that it is unavoidable. {Footnote 26}

Memes' and genes' environments

What is the environment of a particular meme? Or, to borrow a further idea from evolutionary biology, what formed its "environment of evolutionary adaptedness" - that is, the (historical) environment in which the meme's (or organism's) characteristic adaptations arose and became incorporated. The environment of evolutionary adaptedness may be very dissimilar from the present environment. A central contention of "evolutionary psychology", for example, is that the environment of evolutionary adaptedness which has shaped the "species-typical" psychology of today's humans is not today's environment, but the environment in which our hunter-gatherer ancestors lived before the agricultural revolution. {Footnote 27}

To anticipate by a little the answer to the corresponding question about memes' environments of evolutionary adaptedness: for most of the memes we are familiar with not only do (or did) their EEAs consist largely of other memes, but those other memes were themselves already adapted through memetic evolution in highly complex ways.

One - but only one - of the ways in which a meme's adaptations can increase its meme's success is by helping its incidence in a human population. The compulsive - though arbitrary - power of culture has much to do with this: a meme tends to succeed among its coexisting and competing memes if, for whatever reason, it can predominate in individual humans and among human populations. In this indirect sense memes are democrats; in order to get selected they must "try" to find ways of getting and staying in human beings. In similar fashion, genes "try" to get incorporated in species (or "gene pools").

Selection, invention and intention

There is an important distinction between the environments of evolutionary adaptedness of biological organisms, and those of memes. Biological adaptations arise, are selected for, and become embodied in the organism because they are successful for the organism in its current environment (though they may then endure long after the environment of adaptedness changes - and this includes the other adaptations gathered in the same organism). Natural selection is "blind"; it "tries out" solutions, selecting or discarding them, just on those problems which it can feel under its hands at the moment. The functional design of organisms is not the result of any supraorganic intention. Insofar as we may speak of organisms "trying" out variations, this is a convenient, but metaphorical, shorthand.

With memes, however, it is otherwise. They do frequently adapt to the future as well as to the present and past. Successful memes are (almost by definition) those that adapt most successfully to their actual future. Memes are intricately bound up with intentions, in a way that genes are not. My introduction of intention is a small but significant mutation of Dawkins' meme-concept.

Dawkins conceives of memes as consisting essentially of similar copies in living human brains, and as replicating through imitation. I broaden the matter slightly: one - but only one - of the forms intention can assume is imitation.

An example or two may help illustrate the difference. The meme threatening hell fire, as Dawkins points out

"...is highly effective. It might almost have been planned deliberately by a Machiavellian priesthood trained in deep psychological indoctrination techniques. However I doubt if the priests were that clever. Much more probably, unconscious memes have ensured their own survival by virtue of those same qualities of pseudo-ruthlessness which genes display" (Dawkins 1977, 212).

There are two distinct questions about memes and consciousness here. The first is: Are (human) consciousness and intentions integral to memes' propagation? And the answer, for many memes, is Yes. The second question is: are memes conscious? Dawkins implies that the answer to this question is No. But for some types of meme, at least, the answer may be a complicated sort of Yes.

Take on of the more complex memes in which the hellfire and other memes have been incorporated - the Protestant reformation. When Luther composed his theses attacking the Pope's marketing of indulgences to finance St Peter's, and nailed them on the door of the church at Wittenberg, he was intentionally propagating one complex of memes (armed with people - people who were, in turn, to be armed with Luther's new-forged memes) to compete with another: setting, so to say, one family (or coalition) of memes to catch another. The Roman church had encouraged the commercialization of indulgences as a solution to certain future problems posed by prior memes: Pope Leo X's extravagance and his need for funds to complete St Peter's; and, on the part of the purchasers of indulgences, the dread of hellfire and the intention (or at least hope) of avoiding it in exchange for cash. Fusing the attractions of salvation and economy, Luther's recombined complex of doctrinal propositions spread through Germany "in a fortnight". {Footnote 28}

Notice that the memes involved varied along a sort of spectrum from rather sophisticated ones, that had evolved among and in relation to other memes which themselves already had an elaborate evolutionary history - like Luther's denial that the Papacy could delegate the remission of sins to professional pardoners - to relatively "primitive" ones - like the fear of pain or fire. We may think of parallels, perhaps, with the increasingly complex chemical history of biological evolution, or of analogies with higher organisms, many of which have evolved wholly within elaborate cycles of adaptation and dependency on each other - for nutrients, for shelter and support, for reproduction, and so on.

The evolution of intentionality

Intentionality is involved in generating scientific as well as religious memes. Here is how another biologist, Wolpert (1992, xii), sees scientific innovation, contemplating both his own experience and the overall evolution of science:

"Since science is unique, it is to be expected that scientific creativity has its own special characteristics quite different from those of the arts...Scientific genius is often characterized by a "psychic courage" which requires scientists to include in their ideas assumptions for which they have very little evidence."

Perhaps significantly, Wolpert sees natural science as arising out of the lineage of Western Christianity, with its penchant for logic among a paucity or confusion of evidence {Footnote 29}.

He sums up the problem thus:

"The puzzle lies in how scientists decide which experimental data or which theoretical construct they are willing to give up when these are in conflict" (Wolpert 1993, 116)

The decision what to cling to and what to abandon is not peculiar to science. However, it arises for memes in a way that it does not for genes.

Memes raise a fascinating but difficult question, with roots in the histories of biological reactivity and animal behaviour: that of the emergence of intentionality, self-consciousness, and rational thinking as a function of organic life. {Footnote 30} This is a question I skirt round.

More generally, I steer as clear as possible of general questions about ultimate or essential sources of change in memes. At this stage of our knowledge a piecemeal "natural history" approach, describing memes and some of their adaptations and relationships, seems to me the more useful.

But turning away from theorizing about origins and toward investigating the historical details of particular adaptations, does not mean escaping from the problems of intention. Human history involves the continual inception of new intentions in a least two senses:

- Old humans age and die and are replaced by younger humans who absorb similar patterns of intention; broad, habitual, patterns of intention are (approximately) replicated from generation to generation;
- Among these habitual patterns new types of intention arise, and some of these proliferate powerfully.

Any overview of memes and the patterns of intention linked with them require us to consider types of intention that only arise in fairly recent, historical times. However there may be a compensatory advantage to this: we have fuller and more direct evidence on intentions for the more recent past. Provided we avoid getting hung up on questions of essential or ultimate origins, and concentrate on particular adaptations, we may take advantage of the fact that evidence on the historical past is very rich compared with that on Pleistocene or earlier times. Since then there have arisen many psychological processes and practical techniques that were not around earlier.

Can thinking about memes help us understand them? Can memes and their evolution be studied as phenomena distinct from DNA-based evolution - a little as our understanding of organic life is distinguishable from (though consistent with) physics and chemistry?

We need to take account of intentions. But we must avoid getting bogged down in questions about what intention (or its associated notions: meaning, consciousness, free will, etc) essentially is (or, for that matter, biologically was). Instead I take a fairly matter-of-fact view of intentions and meanings, and ask more prosaic and immediate questions about how they are transmitted, preserved, disguised, enforced and so on. One point I underline is that intentions need not be either individual, mental or subjective. They take effect through minds, but to pass from one mind to another they frequently take extra-somatic forms: for example, in an artefact made by one subject for use or consumption by others. The physical phase of such a meme embodies intention, not only when it explicitly expresses intention (as in a No Entry sign, or an "If ... then ... do ..." instruction in a computer programme), but when its impersonal purpose is implicit in its nature (as in a lollipop, or an airliner)

One advantage of intention is that it enriches the evidential record, at least compared with that left by genes and organisms, whose remains survive mainly in fossils. The primary reason for this is that many memes are made to last - by a combination of invention and selection. This applies to intangible as well as tangible memes; the song survives the singer, though the temple may crumble. Organisms, on the other hand, are designed to reproduce, senesce, and die. Very few individuals provide lasting remains; only their genes are immortal, recombined in their descendants. Whatever the difficulties of interpreting it, the trail of historical evidence is of great importance. As far as carbon-based life forms are concerned, an estimated 99% of the species that have lived to date are now extinct (though, granted, classifying memes among "species" is even more difficult). {Footnote 31}

Limits on change

That history is such an important source of evidence does not contradict the fact that it acts on the present only indirectly, through the structures it has already produced. {Footnote 32} Evolution "tinkers"; it must start from the functional equipment already in existence. We may sometimes feel, as the traveler who got lost in Yorkshire was told: "If tha' really wants to get to Bradford, tha'd best not start from here". But the fact is that all evolution, biological and cultural, starts from where it's presently at, and all adaptation is modification of, and to that extent incorporates, previously existing forms.

In culture, as in biology, ontogeny remains rooted in phylogeny - though not in the same way. For languages based on the Latin alphabet, for example, the QWERTY keyboard, though suboptimal in several respects, has become ontogenetically incorporated in typewriter and microcomputer design. Efforts to step round or short-circuit its irrationality run into memetic obstacles embodied in humans' enculturation and training. {Footnote 33} For memes as for genes, co-evolution - interdependent natural selection of multiple entities - leads seamlessly into irrationality, extravagance and invention. {Footnote 34}

In biological structures variations are more likely to be viable - that is, not lethal to the organism or its offspring - the later they come in the organism's development. {Footnote 35} What the genetic code of an organism specifies is not a depiction of the organism at any future stage of its development, but a developmental programme for the organism's life cycle (including the all-important and oft-repeated "loop" specifying reproduction of the organism's genetic code). The chances of a random change being made early in the program and leaving subsequent steps viable or functional are less than for changes later in the developmental sequence. If we think of one of those many storied buildings one can construct with dominoes on a hard table, it is clear that a very slight disturbance of a domino nearer to the base is more likely to bring the whole thing tumbling down than a similar disturbance to one of the upper dominoes. {Footnote 36}

With memes, however, intentional redesign substitutes, in part, for chance variation. The possibility thus arises (or, to be exact, becomes vastly more probable) of substantial alterations to the base of the structure: substituting dominoes near the bottom, replacing some of them with completely different types of building blocks, or even removing superfluous ones altogether. Consider the following account of meme adaptation. It is Lorenzo da Ponte, explaining how he turned Beaumarchais' *The Marriage of Figaro* into the libretto for Mozart's opera:

"The duration prescribed as being usual for dramatic performances, a certain number of characters generally introduced into the same, and some other prudent considerations and exigencies imposed by morality, place and spectators, were the reasons why I did not make a translation of this excellent comedy, but rather an adaptation or, let us say, an extract.

"To this end I was obliged to reduce the sixteen characters of which it consists to eleven, two of which may be performed by a single person, and to omit, apart from an entire act, many a very charming scene and a number of good jests and sallies with which it is strewn, in place of which I had to substitute canzonettas, arias, choruses and other forms, and words susceptible to music, things which can be supplied only by verse, but never by prose." {Footnote 37}

Human intentions allow meme adaptation to "cut through" or "streamline" existing structures, finding alternative routes to existing or imagined outcomes, in a way that biological redesign cannot. {Footnote 38} {Footnote 39} They also encourage *exaptations* - the turning of existing adaptations to new uses. Indeed, a great deal of cultural evolution consists of inventing new ends which existing means can be converted to propel. {Footnote 40}

Invention and necessity

When they embody intentions, memes in some degree detach them from individual human agents. In one famous passage of his *Decline and Fall*, Edward Gibbon asks about the adaptations to human intentions that made Christianity so successful:

"Our curiosity is naturally prompted to inquire by what means the Christian faith obtained so remarkable a victory over the established religions of the earth. To this inquiry an obvious but satisfactory answer may be returned: that it was owing to the convincing evidence of the doctrine itself, and to the ruling providence of its great Author. But as truth and reason seldom find so favourable a reception in the world, and as the wisdom of Providence frequently condescends to use the passions of the human heart, and the general circumstances of mankind, as instruments to

execute its purpose, we may still be permitted, though with becoming submission, to ask, not indeed what were the first, but what were the secondary causes of the rapid growth of the Christian church?" (Gibbon, XV)

The "secondary causes" of any successful ideology includes myriad of individual human intentions, coherently oriented. Intentions may be embodied in very specific and (especially where expressed in symbolic systems) apparently minor ways.

A further theological meme - that of the Trinity - furnishes an example of this - and of intention's streamlining effects.

Most of today's Christian memes of God descend from the doctrine of the Trinity adopted by the Council of Nicea (325), which proliferated as orthodoxy in the mystery at the heart of the Nicene Creed. How was the tripartite God to be defined in a way which did justice to its family origins, its administrative functions, and the divinity of Christ? The theologians settled upon an ambiguous but precise formula: a single God existing in three persons and of one substance, the Son being perpetually generated by the Father but simultaneously co-eternal with Him.

But they did so only after years of disputation, in which arguments and counter-arguments sprouted vigorously, producing doctrinal tangles which included most of the imaginable ways in which the components of the Trinity could be put together.

Thus one of the key decisions of Constantine's Council at Nicea was procedural rather than substantive: to reduce the thickets of previous controversy, and consider just two alternative Greek terms, differing by a single letter, for describing the identity or resemblance between Father and Son: either St Athanasius' assertive *homoousion* ("of one substance") or the more cautious *homoiousion* ("of like substance") favoured by the supporters of Arius of Alexander.

The single *iota* separating them marked a distinction (as Gibbon faintly exaggerates) "invisible to the nicest theological eye". More visibly, it was expressed in the formidable array of anathemas, against Arianism and other heresies, behind which the Nicene theologians sought to protect their preferred formula. The concentration of intention - in this case organizational and political, as well as theological, shaped formulaic choice and heightened doctrinal creativity. The decision that the doctrinal edifice as a whole should balance on the inclusion or deletion of a single letter was recognition of the many (and often poorly-understood) alternative combinations of formulae that had been advanced and found wanting, many of them before the disputants were born. Barkow (1989, p250) writes of meme variation:

"Some categories or subcategories of cultural information do seem to lend themselves to a "meme" or "culturegen" approach; for example, whether I brush my teeth with a rotary motion or up-and-down and side-to-side. Others, such as my perception of the nature of the Holy Trinity, do not seem to lend themselves to particulate approaches."

This needs qualifying. What may be susceptible to "particulate approaches" are particular variations. These can appear quite local within the overall meme-complex they inhabit, but have very general, and partly intended, consequences for the larger meme.

The point is that apparently trivial symbolic changes can contain large intentions with profound repercussions. When the iota was reintroduced "The whole world groaned and marveled to find itself Arian". The Arians succeeded partly by increasing the infectiousness of their meme, setting their theological ideas to music as popular songs. In the 320's common folk from Alexandria to Constantinople could be heard singing ditties to the uniqueness of God the Father. {Footnote 41}}]

God memes have one distinctive and interesting feature. While they evolve, the object to which they refer, being eternal and unchanging, does not. This furnishes us with a sort of rudimentary experimental control. When God-memes undergo rapid change, we can reasonably attribute this to the memes' circumstances. In the context of our Arian example, the candidates needed to gain the assent of the senior ecclesiastics promulgating doctrine - a requirement that reduced the variants to two, rather simply related, contenders. {Footnote 42}

Selection among biological structures is absolutely "blind", genetic variation arising wholly by chance, while memetic adaptation is only relatively so. The fact that cultural adaptation has intended as well as unintended consequences focuses variation, injecting an element of conscious design and accelerating the incorporation of successful features and the attenuation of unsuccessful ones. The distinction between genetic and cultural evolution is only relative. They combine in domestication, the foundation of much human culture, and, more recently, in the possibilities opened up by direct examination and manipulation of our and other species' genetic material.

The idea that acquired characteristics cannot be inherited is rather basic to biology - now almost one of its defining characteristics. But what phenomena the principle applies to, and in what ways, remains an empirical question. A large part of the study of culture involves investigating how acquired characters are transmitted - and how transmissibility gets acquired or invented.

It is certainly possible, as Delius (1991) argues, that the apparent ability of memes to transmit changes acquired within individual brains (and its corollary ideas, of intention, creativity etc) is an illusion, arising from the very limited extent to which we understand meme selection within the individual's memory and its underlying neural structures. Thus what we call "intention" is in fact a concealed process of random variation and selection within a long-lived host of memes with a much shorter lifespan, analogous (say) to intra-host evolution of micro-organisms' antibiotic resistance. Edelman's (1992) "theory of neuronal group selection" - which draws on our understanding of how immune systems learn - has similarities with this view. {Footnote 43}

I remain agnostic, concentrating on processes of meme transmission between humans, and continuing with the commonsense, or "folk", view of meme change within individuals as (at least partly) "intentional".

Group selection?

For gene-centered biology the vehicles for genes, and therefore the "candidates" for selection among them, are individual organisms, not species. Traits such as genetically transmitted altruistic behaviour (alarm calls at predators) or altruistic organs (mammary glands) or even

whole organisms (sterile worker bees) - which benefit other individual members of the same species can therefore evolve only where the individuals benefitted share genes with the individuals expressing the trait: Hamilton's (? 1964) kin selection, or inclusive fitness. {Footnote 44} This modern, gene-centered view has largely replaced earlier habits of thought which supposed that traits could be selected "for the good of the species" {Footnote 45}. More generally, the appropriate units of selection remain difficult and debated matters in evolutionary biology.

But human beings are sometimes nice to some of those who are not their kin. And some are nasty to those who are close kin. What is more, some people would like to be nicer than they generally are. And prisons, psychiatric hospitals and committees contain yet others who would be even nastier than they are, if they were allowed.

This is where an advantage of treating memes as real comes in. Memes can evolve (and many of them have evolved) powerful and sophisticated means for coercing, motivating, persuading and repelling human beings - fruit, saliva and teeth, so to speak. True, we are still a long way from understanding the "biochemistry" through which these adaptations work. {Footnote 46} But there is less doubt that they exist. Organs - such as patriotism or prisons - that would require group selection to evolve among individual humans may, nonetheless, evolve from variations among memes.

One common characteristic through which natural selection between memes takes place (though it is certainly not the only one) is differences between memes in the numbers and qualities of human beings they succeed in "recruiting" or "ingesting" - a very rough analogy, perhaps, to differences between individual animals of the same species in foraging or predation efficiency. Patriotism (regarded as a virtue, even by the other side) emerges from a long process of competition among loyalties on a variety of territorial, linguistic, etc bases, where the size of groups competing for individuals' loyalties ranges from the family to humanity as a whole. Prisons remind us that recruiting or ingesting support is often indirect. Prison restrains and punishes those it incarcerates, but it *succeeds* by being a morally appealing device for the politically powerful. Its nutrition comes both from those incarcerated and, more importantly, from the values and intentions of the population at large.

These examples contain a more general point: the compulsions of our social world may become more intelligible once we get into the habit of seeing them as efficient meme adaptations, rather than as final causes of individuals' behaviour. {Footnote 47} Naturally, there are many things, such as love, or war, which we can get to grips with only by combining accounts of memetic and genetic adaptation. {Footnote 48} Many memes develop a sort of "territoriality" - personal, not spatial - whereby they include or repel humans according (chiefly) to their memetic characteristics. (The quotation marks are essential, as notions of species, individual organisms, and hence territoriality, do not transfer easily from genes to memes.)

Applied biology - antibiotic drugs, for example - raises the question of who is being domesticated by whom: humans by bacteria, or bacteria by humans? Similar questions arise with humans and memes. Human populations, and their culturally and morally differentiated groups, act as both prey and predators of memes. From our point of view some moral memes - for

example - are frighteningly supra-organic, unpredictable and often rapacious. But from their point of view, memes are just getting on with the everyday business of life. And some memes - some formal organizations, for example - engage in elaborate intercourse with each other. Like you and me at breakfast time, such memes are not concerned with the feelings - still less the intentions - of their sausages, or the atoms (or humans) of which they themselves are composed. They are too busy telling each other their plans for the day, or last night's dreams (and, perhaps, persuading themselves that their dream-work was perfectly proper). We can get inside their skins only by regarding them as being as real as organisms, or persons.

Meta-memes

The assemblages in which memes unite for survival and propagation do not necessarily have physical or even biological foundations. Memes can hang around together for more general reasons, and in more abstract ways. In many cases this is because they have gotten used to each other in the past - as in the specialisms of academic knowledge or the division of labour more generally. But new and unexpected affiliations can also form. Like upwardly mobile football hooligans, memes seem to dissolve and reassemble their ranks for each season (indeed for each match, even each penalty). They form and reform as gaudily clad but often hostile crowds: orthodox versus heretic, U versus non-U, entailed versus excluded, true versus false, and so on and so forth.

Naturally, the patterns of meme-crowds are also memes, and get transmitted around as such. Myths, magic, religion, mathematics etc are (so to speak) "carnivore" memes whose life patterns reflect the general feeding, nesting or swarming habits of other forms. These more specialised meme machines - which, of course, may compete vigorously with each other - are reinforced by numerous forms of invention or recruitment.

Many memes go in for differentiated infection or domestication of human beings, forming a sort of "priesthood" of specially conditioned human types, and evolving markedly different morphologies within their life cycle for more effective spread - that is, for becoming endemic or epidemic in the human population. This point sounds abstract, but is actually quite familiar to the humans who specialise in the initial spread of the more abstract, "spore" memes: ideologists and intellectuals. As Plekhanov expressed it (in one of this century's more successful memes):

"Propaganda is providing many ideas to a few people. Agitation is moving many people by means of a few ideas. And agitation depends on propaganda." {Footnote 49}
Similar infective and inoculative technologies are fundamental to education.

Mememes may succeed by organizing their human disseminators in new and highly differentiated ways, rather as modern military forces employ most of their personnel on administrative, logistical and technical tasks, and only a minority on combat duties (or, perhaps, as parasites may inhabit different hosts at different phases of their life cycle). The military simile is apt, since one important function of such meme meta-machines is to contain and reduce the opposing meme meta-machines of rival meme-complexes. Rivalry is defined by reference to yet other - logical, ideological, and theological - meme complexes.

Here, as in many other meme contexts, truth or falsity are not necessarily the important things, and sometimes they are completely irrelevant. Adaptations are selected according to the maxim:

"My meme, right or wrong!" National anthems and advertising, the defense of orthodoxy against heresy, dictatorship and the doctrine of cabinet responsibility, a national curriculum and a guillotine, hypothesis and experiment, even the conventions of peer review - are various forms that memes' equipment against their competitors have evolved. I do not mean to suggest that truth is unimportant, merely that it is just one category of meme (or meta-meme) among many, surviving as best it can in a testing environment.

Other adaptations

"What are you famous for?" "For nothing. I am just famous." - Iris Murdoch, *Flight*.

Memes do a wide range of things in their efforts to propagate. They rhyme, scan and get themselves set to music; some make themselves sweet, or sour, or both; some exaggerate their obnoxiousness or durability ("The word of God endureth for ever"); some become succinct or memorable, or simply turn up the volume; some parade gorgeous tails - or tales; some sprout wings and take off; some lumber after their mates, or pursue their prey, on thousands of footnotes.

One of the interesting and relatively recent things memes have done is try to emulate the more exact replicative techniques (and the built-in obsolescence) of biological life. This was first and most effectively done with tangible mass production - pins, cars, wedding rings, and so on - but similarly potent technologies are fast developing for moral and aesthetic memes. For both there is a trade-off between durability and cheapness - partly analogous to that between longevity and fecundity in organisms. {Footnote 50}

Many of these cheaper and more plentiful memes require the human beings who use them to be reshaped a little. Schools ensure that hearts and minds develop in accordance with proper templates. {Footnote 51} The development of standardized, quality-controlled production lines seems to require - for memes as much as for genes - the protection of the germ-line from the clamor and accidents which afflict the soma: insulating the design shop and the specialists who work there from the hubbub of the proletariat on the factory floor.

Memes and genes

"Population genetics may be defined as that branch of epidemiology that deals with infectious elements transmitted exclusively from parent to offspring." - GC Williams, *Natural Selection*, p13.]

As meme selection proceeds, the main mechanism emphasised by human sociobiology and "evolutionary psychology" - the adaptive pressures of hunter gatherer life on genetic characteristics of the human psyche - never disappears. (It could do so only if memes switched species.) But as a mechanism of adaptation it acts so slowly and "blindly", it is so relatively inefficient, that its effects are increasingly smothered by more recent, meme-derived and meme-

dependent, mechanisms. Indeed, so relatively rapid is cultural transmission that even memes which deliberately and drastically lower individuals' inclusive fitness (contraceptive technologies, for example) can, when favourably enmeshed among other memes, saturate a human population in little more than a generation.

Ball (1984, 147) suggests a fourfold typology of memes, classifying them according to their adaptiveness for (a) themselves and (b) their carrier-organisms:

A symbiotic meme promotes behaviour that is adaptive for itself and adaptive also for its organism... ("Sex is fun; pass it on.")

A difficult meme promotes behaviour that is maladaptive for itself but adaptive for its organism... ("I know how to do it but can't explain it.")

A parasitic meme promotes behaviour that is adaptive for itself but maladaptive for its organism... ("Praise the Lord; send money; tell your friends.")

A bad meme promotes behaviour that is maladaptive both for itself and for its organism... ("Get away from it all; be a hermit.")

Meme selection tends to favour symbiotic/parasitic varieties, and Delius (1991) further disaggregates this category into its subdivisions in the biological study of symbiosis:

- Mutualism, from which both species gain fitness
- Commensalism, where the guest gains without cost to the host, and
- Parasitism, where the guest gains at the expense of the host.

In such terms a successfully disseminated contraceptive technology - or the thirst for upward social mobility which encourages it - is a "parasitic" meme: one which promotes behaviour that is adaptive for itself but maladaptive for its organism. Memes may vigorously recruit to the ranks of "their" organisms, even when the effect on the organism is to reduce its life-expectancy greatly (as in patriotic or kamikaze-style heroism).

Moreover, as the density and diversity of memes increases, forms can emerge which, though psychologically very powerful, have only slight direct connections with the psychological drives shaped before the Neolithic revolution. Similarly, while it is true that new species evolve to occupy vacant niches, it is equally true that most niches are opened by other species, which define them: the woodpecker presupposes the tree. (Develop on organism and environment.)

The appetite for post-compulsory education, for example, is only remotely connected to the mechanisms emphasised by "evolutionary psychology". It increases generation on generation, despite the fact that educating individual humans significantly reduces their inclusive fitness.

The effect outweighs the increase in parental investment per child. And (as high rates of dropout suggest) the level of human organization (gene, individual, nuclear family, extended family, peer group) of the units of selection is a complex problem.

Uneven, often countervailing, "co-evolution" of memes and people complicate attempts to classify the relations between memes and people. Dennett categorizes memes three ways: good, pernicious, and mixed. His categories are related in a general sense to Ball's, but more pragmatic:

"...many - most, if we're lucky - of the memes that replicate themselves do so not just with our blessing, but because of our esteem for them. I think there can be little controversy that some memes are, all things considered, good from our perspective: ... such general memes as music, writing, education.... The Marriage of Figaro, Moby Dick, and returnable bottles...Other memes are more controversial; we can see why they spread, and why, all things considered, we should tolerate them, in spite of the problems they cause for us: shopping malls, fast food, and advertising on television. Still others are unquestionably pernicious, but extremely hard to eradicate: anti-Semitism, hijacking airliners, computer viruses, spray-paint graffiti." (Dennett 203)

Dennett's "our" and "we" contain a problem. I mentioned it earlier when I referred to "humanist" illusions in studying memes. Why are "pernicious" memes so hard to eradicate? (Those that are readily eradicated cease to be memes at all.) Even "pernicious" memes are good from some peoples' perspective; that is the major reason why they are so hard to eradicate. One person's meme is another person's poison, but the reverse also applies. Graffiti and racism would not need control if there did not exist reservoirs of support for them in the human population. Many memes divide people, rather as diet divides species, or reproduction divides sexes. {Footnote 52}

A "pernicious" meme (in Dennett's terms) is one that changes categories (in Ball's terms) - as you shift from organism to organism or from perspective to perspective. Many memes are of this type, or contain such components. Ball's typology classifies behaviour socially according to its effect on memes (how far does it promote the meme-type's replication and proliferation in the society of memes), but only individually for people (how does it affect the individual's functioning). This may be why his example of a symbiotic meme ("Sex is fun; pass it on") seems slightly unconvincing. Societies persist and expand even with powerful memes prohibiting and restricting sexual activity. Indeed human societies, as institutions for raising single, socially-competent offspring through protracted juvenile dependency and heavy parental investment, depend on such memes.

Putting Dennett's and Ball's typologies of memes side by side underlines the fact that a framework for understanding organism-meme co-evolution must take account of the replicative machineries of each. Dennett's categories do not really distinguish mechanisms of meme replication or variation in memes' replicative effectiveness; Ball's do, but only to the extent of distinguishing memes that transmit well (by whatever means) from those that do it poorly, and transecting that distinction with a comparably coarse distinction of adaptiveness for the individual human carrier.

It seems to me unlikely that a satisfactory framework can be developed by multiplying such distinctions: the number of categories would explode far faster than their discriminative potential. I return to this problem below, when I discuss the "standard social science model" versus "evolutionary psychologists'" collections of specific adaptations. {Footnote 53} I shall also

return to the question, implicit in Ball's and Delius' "parasitological" classifications of memes: what sort of memes, and in what sorts of ways, can be considered analogous to organisms or species?

Meme replication and imitation: humans and other species

What can we say about how memes reproduce and proliferate themselves? The differences with biological organisms are at least as important as the similarities. Memes, like genes, do replicate (as Dawkins has it) by "imitation...in the broadest sense". But we must be cautious against interpreting "imitation" *over* literally. {Footnote 54} Although imitation may be the principal means of cultural transmission in other species than humans, in humans it is only a particular case. (I leave aside the interesting problems posed by human training of other species. {Footnote 55})

When scientists studying primate behaviour watched a troop of macaques trying to extract food grains that had been mixed in sand, it was a middle-aged female who first puzzled out how to separate out the grains from the sand (she did it by putting the mixture in water, so that the sand sank, while the grains floated). In this species the innovation spread through the troop by imitation, becoming generalised in a few generations. {Footnote 56} We might describe it as becoming "fixed" as an adaptation of the monkeys' culture - if it were not for the difficulties of applying notions of adaptation and speciation to culture.

Other cultural behaviours among animals pass between individuals by more restricted imitation. Local "dialects" of bird song, for example, are transmitted from mature adults (with by-then fixed song patterns) to fledglings during the latter's "sensitive" periods (Catchpole 1986, Lynch and Baker 1993).

Among human beings equipment for meme replication and transmission has become specialised and highly elaborated. Even where cultural transmission is more-or-less replicative, it may still be rather indirect, the "teacher" not actually doing what the learner is learning to do - and sometimes the latter not doing it either. Moreover replication of behaviour is only one type of cultural transmission. When we ask empirical questions about some of the arrangements memes have evolved to propagate successfully, we should bear in mind that meme propagation does not take place only by imitation - or, like genes, by the use of physical templates and moulds (though it is sometimes does - as in printing or factory production more generally). {Footnote 57}

Moreover, even insofar as replication is involved, there are other fundamental differences. Memes adapt not only particular variation by particular variation, but also by rewriting of the codes in which they are inscribed and transmitted. This can be quite literally the case. The evolution of language, writing, or the alphabet, has revolutionized the overall ecology of memes almost as fundamentally as the cell has revolutionized that of life. In both cases a "pause" for investment in structure pays off as faster evolution subsequently. But one difference is that memes have already spent a significant part of their histories "tinkering" with the codes they themselves are inscribed in, and, what is even more important, devising new materials to write on and with; this is a matter that genes have only recently started to address.

Variation and differentiation among memes

What are the sources of variation in memes? We already know, in general terms, that the sources of memetic variation are wider than those of DNA-based life, since they include both random replication errors ("mutations") and deliberate or partly deliberate variations of design. Does the biological analogy, at this point, career off into unmanageable dissimilarity?

Not, I think, if we are careful. Let us prune the problem down with a narrower analogical question from biology: what sorts of arrangements have genes (and memes) evolved in order better to control their own variation and to increase the evolutionary advantages they can derive from it within their particular environment? For genes, remember, the particular environment is very largely made up of "adjacent" genes. What sorts of adaptations have gene-complexes and their survival machines evolved in order the better to regulate their own evolution?

Biologists regard two general forms of differentiation as particularly important among genes: speciation, and sex. Organic life separates its forms into isolated gene pools. And, within many of those pools, it generates opposite processes which continually stir up and remix the gene pool from generation to generation. One of the most important of these is sexual recombination. Speciation, often in combination with sex, bifurcates the "bush" of evolution. There are numerous problems in the relations between (biological) speciation, and sex, and evolution. But our main question is: can we point to analogous mechanisms for cultural - memetic - evolution? I believe we can.

One of these we can describe, as a first approximation, as combined specialisation and concentration of memes. It based on the tendency - indeed the necessity - of memes to "cluster" according to similarities and complementarities of function. This tendency is so general that it is easy to overlook it. Selection among and in favour of more robust meme complexes - and therefore of larger and more complex ones - tends to eliminate loosely-bound memes, just as natural selection acts against the re-emergence of very short DNA sequences. {Footnote 58} {Footnote 59}

The human structure of culture

Some types of clustering are rather closely grounded in cultural evolution's biological basis - that is, in the lifestyle of a socialising savanna primate with an erect gait, reversible thumbs, moderate sexual dimorphism, single offspring, a prolonged fetal/juvenile phase, a large cranium, and a typical life cycle of a few decades. Just as genes build up their "survival machines" - organisms - over vast periods of time as slow, imprecated accumulations of adaptations to long but finite DNA sequences, so culture develops through the more - and less - gradual succession of meme adaptations. This sort of "clustering" - perhaps "chaining" would be a better term - seeks, often literally as well as metaphorically, to exploit the finite capacity of individual human beings by combining them in organised ways. The sexual and occupational divisions of labour are central examples. Each new modification starts from the shapes set by previous cultural evolution. Neither "clustering" nor "chaining" are ideal terms; perhaps "cohesion" or "integration" would be better.

You can get a cultural quart into the biologically given pint pot - but not immediately, and only through a variety of indirect means. You can stretch the pot just a little (though the anatomical compromise between brain size and human birth canal has already set a tight limit on this). You can redesign the pot a little - which may also involve reorganizing the pottery. More important you can increase your overall meme capacity by overflow and interface devices: ducts, siphons, membranes, tubes, pumps, valves and so on connecting the pots one to another and allowing - or driving - their contents to move to and fro between them.

Even more important you can work on the contents of the pots, compressing, concentrating, summarising, generalising, enriching, so to speak, the cultural soup, so that any given configuration of pots has a greater nutritional capacity. And, perhaps most important of all, as the cultural broth cooks and condenses, parts of it will take solid shape, "caramelising", so speak - and (to conclude the domestic metaphor) these crystallising solids offer - among other things - possibilities for making new types of pot and - no less significant - new types of connections between pots. Of course, many of these constructions are relatively unsuccessful and are sooner or later redissolved into the memetic soup. Others, however, endure or get replicated. And as they do, they vary.

Human beings are certainly not the only organisms to link intentions or goal-seeking behaviour over time or across individuals. {Footnote 60} But they are distinctive in the elaborate chainings of intentions that they sustain and wield. In us memetic evolution has chanced across a species that can bond together vast linkages of memes. They and we form "strategic" structures that, pushed at one node, produce action, both intended and unintended, at enormous spatial, temporal and personal distances. When the ideogram-reading Korean factory worker stenciled on the packaging of my personal computer the roman lettering that guided it to my desk, s/he also allowed me to quote to you Aristotle's definition of man as a political animal, and caused this paragraph to carry its meaning from me to you.

Most of these great "chainings" of intentionality are invisible or incomprehensible to the individual humans who link them at particular loci, but through socialisation they come to participate in them with impressive facility and confidence. One of things this has encouraged (or selected for) is our ability to recognise and pursue - individually and in concert - large and remote purposes. Hence our species' itch for meaning in life.

Literacy

One of the most familiar forms of clustering among memes is expressed as cultural differentiation and occupational specialisation between people. Consider one important type of this, which also fixes and transmits intentions in tangible form: writing and associated skills. Like all culture, writing and reading have evolved through increasingly complex differentiation. Originally they were arduous, highly specialist skills, never mastered by more than a tiny, relatively privileged, section of the male population, who learned their scribal skills in a form of lifelong apprenticeship. {Footnote 61} Today fluent literacy is general, and has integrated itself into numberless other technologies.

Between then and now there has occurred a cumulative series of memetic innovations, of which one of the most important is the invention and imposition of the phonetic alphabet. This reduced writing's total of "atomic" symbols to a couple of dozen, and now allows it to be mastered by most six year old humans. There are many others, not least the development of the key means through which I (though distant from you, and perhaps dead) am enabled to speak to you: silent reading, and modern western punctuation. {Footnote 62} To return to our metaphor of pots and cooking, the history of writing is one of experimentation and successful innovation in making connections and interflows between pots and between connectors.

The Greco-Roman alphabet, for example, has proved a remarkable success through simplifying the meta-connection between spoken and written language. In contrast, Chinese ideograms lack the direct linkage between script and pronunciation. Spoken Chinese evolved large differences between geographically separated areas of China, with the result that officials who corresponded without difficulty could, when they met, sometimes not understand each other through speech {Footnote 63}. In recent times there has been persistent pressure on Chinese to be more conformable with the Latin alphabet. {Footnote 64}

Writing is an example of equipment that meme-complexes have evolved to reduce and correct copying errors in replication. Writing reinforces memes by extending their persistence through externalised physical texts, which fulfil some of the functions of transmission between people in non-literate cultures. It slows (or stabilises) "drift" in transmission; subsequent inventions, such as printing, further strengthen error correction. Printing does this more efficiently, essentially by increasing the resources devoted to error-checking. Printing with moveable alphabetic type, which reduced copying errors in scholarly publishing by an order of magnitude, type made Europe's scientific revolution possible. {Footnote 65}

The history of writing, and meme evolution in cultures embodying it, suggests something else. What once filled a few pots right to the brim (literacy) has now, through distillation and some other chemistry, become an unremarked minor ingredient in the contents of virtually all pots. But - since culture, too, abhors a vacuum - the spaces thus released (and already suffused, so to speak, with literacy) are soon filled with new - and newly differentiated - contents. These processes of concentration, accompanying the growth of the total of human knowledge, are the obverse of the continual recomposition of specialisms.

Academic knowledge

The modern academic division of knowledge offers an example. The boundaries between different disciplines and sub-disciplines are rigid in the short term, but more mobile in the long term. But focus, for a moment, not on the detailed placing of divisions, but on their general scale. Very approximately we can discern limits to the scale at which specialist academic disciplines can "deposit" themselves in and around individual humans. One minimum limit is set by the human life span, the period of maturation and working life, and the existing forms of specialist culture embodied in education - the duration and scope of the undergraduate curriculum, graduate training, etc. The "Not my period..." by which the twentieth century medievalist affirms and distinguishes his credentials is the lineal - we might almost say embryological - descendent of the elongated apprenticeship of his cuneiform scribal ancestor.

Humans' physiological scale sets a variety of such limits. The span of consecutive adult attention sets the optimum duration for a dramatic performance, around one-and-a-half hours - which proves also to be about the same time typically allowed for classes in higher education. In each case the amount, and complexity, of the matter for exegesis must be constrained in order to be effective. If the producer wishes to push the duration, s/he is well advised to punctuate the proceedings with intervals, or, in extreme cases - Wagnerian opera, for example - with dinner breaks.

When a segment of culture - a population of memes, like science, or academic learning - comes to be finely divided among humans, both the memes and the humans must be organised. The memes are grouped in part to realise currently available economies of human effort involved in learning (and therefore teaching) them. Academic specialisation and the internal organisation of curricula express adaptation of this sort. Their groupings bear no very direct relation to what memes are "about"; the arithmetic developed on fingers later gets applied to football coupons and physics. But one thing the groupings *are* compelled to stay in close contact with is their own past histories. At this organizational level academic specialisms are largely held together by their shared historical descent in joint "survival machines" - subjects, textbooks, institutions, etc. But there is a positive side, in that crowding promotes synthesis: the importance of a scientific work (as the mathematician Hilbert remarked) can be measured by the number of previous publications it makes it superfluous to read.

Other limits of scale are set by the natural history of institutional life, together with some elements of game theory. For a subdiscipline to nucleate out requires, on a typical faculty board, a minimum coalition size of about three or four, or perhaps a little more. Two people is rather rare; perhaps it is too few for comfort, or for political triangulation. Barkow (1989, pp 12-4) emphasises ways in which interdisciplinary frictions and methodological spaces between disciplines may mutually sustain each other round historically arbitrary "cores". The mechanisms, he holds, are rooted in academics' appetite for reputation (see also Whittlely 1985). Macro factors also play a part: the viability of journals, the scale of experimental work and the numbers and funds required for it, and so forth.

Cellular knowledge

Academic understanding and science, like much of the rest of human knowledge, develop "cellularly". Of course there are extra-cellular materials and tissues as well as intra-cellular ones, but understanding what goes on around and between cells depends heavily on our understanding of individual cells and their internal mechanisms. Human biology and organizational history set elastic but finite limits both to the possible functions and sizes of cells, and to the next modifications of existing organs. Bodies of theoretical knowledge become institutions, not only in a bricks-and-mortar sense, but in the self-regulating sense of consisting in a settled division of skills, training and effort among (replaceable) human beings.

Tensions persist, especially at the boundaries of different disciplines and - equally importantly - at the potential boundaries between disciplines which are presently far apart. But everyone now uses, every day, myriad artefacts, conventions and theories which they are quite incompetent to understand or maintain, and which to most users are "black boxes". Does this mean that common

sense is being overtaken and absorbed by specialised knowledge? Well: yes and no. Specialised "research" organs continually ingest new material. The products of some of this, digested, then pass along general purpose channels to power and build the organism. The cathode ray tube, or slogan, or drug, or electronic charge card, or tax loophole - meme - proposed today by a few specialists gets embodied as tomorrow's daily, commonsensical implement.

Science

"Let her and Falsehood grapple; who ever knew Truth put to the worst, in a free and open encounter" - Milton, *Areopagitica*

Milton's conditions for truth are poor ones for science. The memes of theoretical natural science, as Wolpert (1992) points out, are highly "unnatural" memes, remote from "common sense". Like cattle or sheep, they have been bred for generations into the forms preferred by their domesticators (of whom some of the most important are other memes). Testability, generality, uniform vocabulary, unambiguous meaning, internal consistency, and so on - even taken singly such traits are rare memes, and to assemble them all requires long intentional selection. The domesticated memes of theoretical natural science, having embodied such significant adaptations to artificial circumstances, could no longer survive reintroduction to the wild. They can live and breed only with the aid of rather complex arrangements to sustain them. The cultivation of theoretical science (like keeping sheep) has come to rely on auxiliary breeds, such as scientists - rather like sheepdogs, who keep the flock together and bark at intruders. By comparison, much social science consists of more "common sense" memes, less "deformed" by domestic breeding. They more resemble semi-domesticated breeds which forage freely on the mountain slopes in summertime, but are herded in for the winter. {Footnote 66}

One of the most interesting of domesticated organic species is humankind: interesting because humans are self-domesticators. We serve as both sheep, and sheepdogs, and instructors of the sheepdogs. To instruct each other and ourselves we deploy memes. We are now far too far domesticated, too dependent on memetic cultivation, to survive in the wild. {Footnote 67}

Do memes have "survival machines"?

When I referred to individual people as "vehicles", each transporting a collection of memes, I was using a rather approximate analogy. For gene-centered biology the fundamental unit on which (biological) natural selection operates is the gene. Organisms - the expressions of developmental programmes inscribed in genomes - are differentially selected, but what is important is that some genes get selected in preference to their rivals. Organisms are "survival machines" built by combinations of genes (genomes) as their means for survival, replication and proliferation.

In multi-celled organisms, the genome builds "survival machines" at two interdependent levels. At an aggregate level the genes specify a developmental program for an organism. But, more immediately, they specify a developmental program for each cell, with the site and context of each cell interacting with the genes to determine the cell's destiny as a component of the whole organism. So genes are carried and expressed in "survival machines" at two levels of

organization; individual cells develop so as to work effectively within a whole phenotype; the gene's chances of being transmitted reside both in the attributes of the whole organism and in the attributes of individual cells.

How far could we use an analogous model for memes? For example, could we think of an assemblage of memes being brought together in the socialisation and education of an individual human, then of the interplay of suitably prepared individuals in memetic "organisms" - as conventions, rituals, institutions? Culture, on this view, would be reproduced through processes of replication on (at least) two levels: individuals, and institutions.

The parallel has its points, but also its limitations. Certain memes (a common language, for example) are involved in the formation of all or virtually all individual humans within a given (national or linguistic) culture. Like the common genome in cells' nuclei, it is repeated almost identically in all the "cells" of the "organism". But the particular part that a cell is called upon to play within the life history of "its" organism is affected not only by the developmental program written in the genome, but on the time and the anatomical and physiological context under which the developmental algorithm of the individual cell starts running and gets committed (i.e. where and when it is formed). The genome of every cell plays the same basic melody, but on an instrument, at a pitch and volume, etc which depends not only on what is in the score, but where within the orchestra the instrument develops. Like multicelled organisms, the operation of an organisation as a whole depends on a complex differentiation among parts which are formed on a modular basis. {Footnote 68}

Perhaps, though, the orchestra metaphor has allowed us to slide too easily from genes to memes? One key issue is how far we can identify things which, replicated across individual humans, help us account for the characteristic, enduring qualities of institutions (or organisations, or cultures) across generations.

Darwinian evolution is not confined to organic life-forms, nor is it dependent on particular mechanisms of either replication or reproduction. Organisms, like cells, descend from similar parents, often by the more roundabout processes of sexual recombination. Persons are culturally assembled from a range of other people and memes, some closer, some remote. For example, children acquire much of their first language in imitative, repetitive play within the nuclear family: the "mother tongue". However, they acquire literacy later, in forms which are critically dependent on earlier language development, within formal organisations specialised for that purpose (schools), overwhelmingly composed of other humans who are not close genetic relatives. Literacy develops in the individual human partly by processes of reciprocal imitation with others (peer groups), and partly through functionally specialised humans (teachers).

Views about meme vehicles

In fact, writers about memes have rather various views of what relationships hold between memes and entities that serve as their "survival machines" or "vehicles". Dawkins, in his original formulation, starts from the view that memes replicate by imitation. He then speaks at various points of a variety of different things which can transmit memes: individual humans (or their brains), ideas, songs (as in Auld Lang Syne), physical artefacts (such as hymn books), symbolic

systems (such as languages), formal organizations (such as churches), and social institutions (such as priestly celibacy).

Dennett argues similarly:

"Genes are invisible; they are carried by gene vehicles (organisms) in which they tend to produce characteristic effects ("phenotypic" effects by which their fates are, in the long run, determined. Memes are also invisible, and are carried by meme vehicles - pictures, books, sayings (in particular languages, oral or written, on paper or magnetically encoded, etc). Tools and buildings and other inventions are also meme vehicles. A wagon with spoked wheels carries not only grain or freight from place to place; it carries the brilliant idea of a wagon with spoked wheels from mind to mind. A meme's existence depends on a physical embodiment in some medium; if all such physical embodiments are destroyed, that meme is extinguished... "Meme vehicles inhabit our world alongside all the fauna and flora, large and small. By and large they are "visible" only to the human species, however. Consider the environment of the average New York City pigeon, whose eyes and ears are assaulted every day by approximately as many words, pictures and other signs and symbols as assault each human New Yorker. These physical meme vehicles may impinge importantly on the pigeon's welfare, but not in virtue of the memes they carry - it is nothing to the pigeon that it is under a page of the National Enquirer, not the New York Times, that it finds a crumb." (Dennett, CE, 203-4)

Let us look at some of these alternative meme vehicles in a little more detail. To what extent are they actually alternatives - rather than being, say, different phases of a developmental sequence? By looking at this we may be able bring the role of "imitation" in meme replication into clearer focus, and unpack some of the ways in which memes "leap" from one subject's mind to another's.

Physical artefacts

"No part of the walls is left undecorated. From everywhere the praise of the lord is drummed into you." - Nikolaus Pevsner, London. "Who *is* the Potter, pray, and who the Pot?" - Rubayat of Omar Khayyam

Even in some of the "simplest" forms of artefact-making there can occur great stability of the artefact's form over many (human) generations. The stone tools of pre-agricultural humans, for example, evolved fast in terms of biological time, but very slowly compared with today's rates of technological change. Their characteristic forms were highly stable in the shorter term. They developed over millennia through sequences of styles in the end-product - for example, flint arrowheads. The overall evolutionary development through recognizable styles often allows archeologists - like paleologists - to date and source particular examples rather exactly. The evidence as a whole points to increasingly competent and exact processes of imitation.

Most (physical) artefacts arise from processes of replication and imitation. But the two are not the same. What, precisely, got imitated in the manufacture of early stone tools? It is a reasonable surmise that what was being imitated, from human to human, elder to neophyte, was not (or at least, not only) some finished example of the artefact itself (the flaked and shaped arrowhead) but rather the whole developmental sequence that led to it: from the searching out and selecting

of suitable pebbles (all of which would be quite different from the finished product), via rough shaping, finishing, selection and perhaps grading, to final use. With our modern, elaborated division of labour between people the developmental processes of an artefact - considered as one sequence, from location of raw material to finished artefact-in-use - has been broken into numerous lesser, recombining, parts and much of it has passed beyond any one individual's view. If we want to reconstruct it we must do it in our mind, with the help of some very recent artefacts (including the technical and social sciences).

What gets imitated, therefore, is not immediately the finished, developed artefact, but its process of manufacture or development. And one of the intermediate products that must be reproduced is the artefact maker. {Footnote 69} Imitating another's artefact is, first of all, imitating the Other, and that imitation is itself a developmental process. The education of an individual in a skill - the skill (or more exactly, the ordered sequence of sub-skills) for producing an artefact-meme, in this case a Neolithic hunter's particular style of arrowhead - requires that the particular meme's specialised reproductive equipment - the apprenticeship of the arrow maker - itself be reproduced. Neolithic sites can often be recognized by their accumulations of unfinished tools and related debris, by-products of the joint production of tools and toolmakers. Education, including the imitation of other already-educated humans, is how a technology, a language or a culture endures across generations. As Dennett puts it:

"The haven all memes depend on reaching is the human mind, but a human mind is itself an artifact created when memes restructure a human brain in order to make it a better habitat for memes. The avenues for entry and exit are modified to suit local conditions, and strengthened by various artificial devices that enhance fidelity and prolixity of replication: native Chinese minds differ dramatically from native French minds, and literate minds differ from illiterate minds." (Dennett, 207)

Much change in artefacts, as in other memes, is marginal. It arises by design but not by inspiration. The usual propellant is dissatisfaction with existing forms and the consequent, iterative search for an improved form. Henry Petroski, writing on the history of design, argues that, contrary to design theory's conventional wisdom that "Form follows function" (design theorists being, so to say, the ideologists of successful designers), it is more accurate to say that "Form follows failure", and to see the inventor primarily as a critic, not as an artist (Petroski 1993; cf Oscar Wilde, *The Critic as Artist*) {Footnote 70}

Life cycles and art cycles

"God is really only another artist. He invented the giraffe, the elephant and the cat. He has no real style. He just goes on trying other things." - Pablo Picasso (Gilot and Like, *Life with Picasso*)

Even in creative modern art, much modification of memes remains marginal. Here is how David Hockney improved his memes to help them gain better access to human minds, "the haven all memes depend on reaching":

"I realized that was the way most people were going to see this work, in this form of reproduction, because the number of people who could see the real piece, which is ten feet across, would be quite small. If you sell five thousand posters, not only are five thousand people seeing it, but maybe ten other people see each poster, so it means a lot of people. Therefore, I thought if that is the form it is going to be seen in mostly, let's make sure we do it as well as we can technically. That's why my posters began to be rather good. We took a little more trouble just making sure the work was photographed very well and the printing was of good quality. I was surprised that so few artists seemed to take an interest in that. I think now more and more artists are becoming aware that reproductions of their pictures are the way most people see them. After all, artists should have known that, because that's the way they themselves saw a great number of pictures." {Footnote 71}

Hockney goes on to describe how memes not only enter minds, but re-engrave them - how repotting remakes the repotter:

"For me, reproductions of my work were something that became more and more important, beginning with my first big book, *Hockney by Hockney*. I realized that not only had I got my work at my fingertips, I could flick through it, flick through my life as it were; I realized too that others could flick through my work, and I think this is also a part of art." (Hockney, 1993, 115)

Only in the fairly recent past (about the last two centuries) has human society become information-rich through memes capable of mass manufacture or transmission. Where, as recently as the last century, individual humans competed for news or entertainment, now the boot is on the other foot, and an "info glut" of media competes furiously to be noticed by as many individuals as possible. {Footnote 72}

Post modernity is society in which the key scarce resource is public attention (Baumann). But competition for this resource takes place among memes whose basic structures evolved in information-poor societies. A fifteen second television advertisement may assume fluent literacy in its audience, flashing its message in glimpsed, oblique word-fragments. But the alphabet it uses evolved nearly 3000 years ago in the eastern Mediterranean in peasant societies where a large majority of people could neither read nor write, and a large proportion had never *seen* a written artefact. The conservative element is not the physical artefact, whose design and production methods have been many times revolutionized, but the symbolic conventions with which human generations engrave their successors. {Footnote 73}

Even apparently "simple" artefacts, such as our Neolithic arrowhead, raise the questions: What gets replicated? What reproduces? What, if anything, corresponds to the biological organism in population genetics? One of the difficulties in reconstructing the development programs of memes is that they involve the confluence of other and successive tributary inputs. "Tributary" itself oversimplifies: many intermediate products serve as input to several outputs. And many output-memes can be produced by a variety of combinations.

Over time combinations vary and alternative combinations get selected - evolve - so as to "enhance fidelity and prolixity of replication". Selection takes place partly through and partly

outside human intentions. An important part of technical evolution is change in the artefacts used to produce other artefacts: finger-molding of clay, the potter's wheel, the glass factory. Innovation in the end product is often an almost incidental result of selection among variants at earlier stages of a developmental sequence. Additions to the repertoire of intermediate artefact-memes - the wheel, iron smelting, paper, the steam engine - bring change virtually throughout the system of production.

How do meme-vehicles reproduce?

Where, then, in all this, should we identify memes and their vehicles? Is a completed artefact a "stably co-adapted complex of memes", or is it just one phase of the former's life-cycle, its "vehicle" or "survival machine"? If the latter, where are the memes - invisible, according to Dennett - that persist by replication through the life-cycle of the organism? How are memetically-structured (trained) human brains integrated within artefact-memes' development sequences? In particular, what gets replicated when the imagined idea of the pot gets shaped on the potter's wheel, or (to invert the problem of signifier and signified) when repeated practice at the elbow of a skilled potter educates a new potter?

Two differences between genes and memes (or, at least, the artefact forms or phases of memes) seem to me particularly important. In the first place memes in general have no physical "stencil", analogous to nucleic acid sequences, preserved through transcription and replication right across the life cycle; the mechanisms of replication are quite different. In fact DNA does not replicate itself directly: its double strands first separate into two single strands, each of which then bonds to free bases to re-form the double structure of DNA. There are more general reasons why nothing can replicate itself directly, producing itself, like the Christian god, from out of itself; the same thing cannot act simultaneously as maker and made. Replication (and its conscious form, imitation) must occur through at least a double transcription. {Footnote 74}

Secondly, artefact-memes can tolerate far more radical changes in the developmental sequences from which they issue than can genes and their survival machines. Major technical changes and substitutions can be introduced, a long way ahead of the finished product, which are not lethal but, on the contrary, increase both the efficiency of replication and the quality of the product: paper in place of parchment; animal muscle, steam, or electricity instead of human effort.

These two differences lead us into further problems. If biological replication takes place at two general "levels", the cell and the organism, how many levels can we point to for memes? What is a meme's equivalent of the organism's life-cycle, in which development takes place through a structured sequence of forms, including fertile phases but ending in the death and disintegration of the organism? Indeed, can we draw any generally useful distinction between genes and their vehicles or survival machines? Let us look at some examples of (complex) memes and the problem of analysing them into their conceptual components.

Memes must replicate. For them to do so there must be adapted equipment or arrangements in place. But must memes be self-replicators? Physical artefacts, on the whole, are not - if we leave aside particular and arguable examples, like machine tools, or software for writing software. Arrowheads do not reproduce arrowheads, and the inputs to a baked bean cannery don't include

tins of baked beans (they do include uncooked beans, though slightly fewer emerge tinned at the other end). The meme-artefact has - so to speak - externalised its reproductive arrangements (the physical inputs and the meme-structured bean and can makers and their motives), and these are renewed through separate cycles of replication: the production of beans and tomatoes, steel, paper labels etc, and the cycles of socialization, education, exchange and employment that deliver the right mix of skilled and motivated workers to operate enterprises (for making beans, for making bean and can making equipment, and for making bean makers). Artefacts are produced by means of artefacts, commodities by means of commodities, people by means of people, and each of these have histories of memetic evolution. People and their psyches (and beans and their life cycles) also have histories of biological evolution, fixed as adaptations in almost all individuals.

Perhaps, though, it is more helpful to think of artefact-memes not so much as having externalised reproductive apparatus, but of the physical output as being part - just one phase - of a larger and longer self-replicative cycle. Biologists are used to thinking of organisms as self-reproducing machines, and of their design features as selected to be functional from this point of view. Could we not, by extending meme-processes, identify replication cycles which correspond more closely to those involved in biological reproduction?

If it makes good sense to biologists to think of a bird as an egg's way (or its genes' way) way of making another egg, or of flowers and their pollinating insects as parts of common reproductive cycles, does it not make equal sense to think of the species of bird as a particular type of nest's - or song's - way of replicating into another nest or song? And, by extension, can we not think of the bean cannery and its auxiliary agriculture as (another, intersecting) replicative route involving beans? {Footnote 75} Plants have "learned" over evolutionary time to use the distinctive behavioural patterns - the proto-motives - of insects, birds and mammals as they feed, nest and excrete to pollinate their flowers and disperse their seeds; similarly artefacts have adapted to use humans' complex patterns of behaviour and motivation as reproductive equipment.

In fact, with higher forms of moral meme, the idea is already familiar to us. We have no especial difficulty in thinking of generations upon generations of human beings in the service of art, science, the mission of the church, or the juggernaut of progress. Evolutionary biologists do not think - except as a deliberate approximation - of species' evolving in a static niche, but of the co-evolution of many species (or, if you prefer, of arrays of many niches, and of the species which define and compose them {Footnote 76}).

As far as physical artefact-memes are concerned, we cannot point to common physical structures at the base of their forms of replication. Moreover their forms of reproductive separation and isolation are quite different from DNA's - another aspect, from one point of view, of the externalization of their replicating equipment. Replicating cans of baked beans need never involve starting with other cans of baked beans - though it well may, if the canners retain their appetite for baked beans. More generally the replication of artefacts, commodities and people takes place by means of artefacts, commodities and people - but different ones.

Cells, organisms and species can each be regarded as different routes for complex molecules' self-replication, and self-replicators' self-replication, and so on. DNA's replicative cycles vary,

and selection takes among the variants, speciation being an advanced result of the process. The effects of biological evolution include many striking examples of functional integration and trade off between competing variants and meta-variants of nucleic acid sequences: exquisite balances among genes between the needs of survival and replication; intimate and exact co-evolution of functions among several species; ecologies as dynamic equilibria of (specialised and reproductively segregated) populations of molecules, cells and species.

Species, however, like individual organisms (or birds' songs, or candles' flames) are not static objects, but temporary processes. There is always the possibility they may go extinct or subdivide. For this reason the biologist GC Williams emphasises the clade as the general unit of selection. A clade corresponds to a set of entities of common ancestry (monophyletic). It may be a strain, a species, or a larger category. Clades "compete" at many levels, but

"The ultimate prize for which all clades are in competition is representation in the biota" (Williams 1992, p25) {Footnote 77}

Recall Dennett's similar observation about memes:

"The haven all memes depend on reaching is the human mind..." (Dennett, 207)

But is Dennett's formulation a necessary truth about memes - that they can only infect human minds? Dennett adds that a human mind is itself merely a particular type of meme-inscribed artefact. Culture consists not only of minds but of many other artefacts. Cultural and technical evolution has seen memes develop increasingly elaborate, varied and circuitous routes outside minds, many of them inscribed in codes that evolved first in human minds. Could memes emancipate themselves from human beings altogether? They show tendencies to do in various directions, from the permanent transfer of memes from human culture to that of other animals [tits and bottles, bower birds], to incipient pattern recognition and intelligence among computers.

The meme-family of conspecific aggression among social mammals (and its inhibitory limitation) long predates hominids. But with the aid of humans it has "domesticated" many other vehicles: human artefacts from stones to nuclear weapons; other species (especially horses); more general memes of cohesion among humans (from parental investment to proletarian internationalism); and numerous more-or-less complex formal organizations, from the warrior band and the air force, to space technology and the Red Cross. Warfare, having engraved itself among our memetically transmitted preferences, seem to be proliferating by emancipating itself to an increasing degree.

Perhaps Dennett's insistence on the human mind as memes' irreducible "haven" is a residue of the "mentalism" or "humanism" that has - understandably - proliferated in memes about memetic evolution? Conclusively to establish the need for Dennett's "haven" we would, in a sense, need to prove a negative: that no meme could remain aloft indefinitely without perching for rest in a human mind.

There is nothing inherently impossible in the idea that the lineages of patterning that form life could be coded in other replicative structures than nucleic acids. Cairns-Smith has developed the

speculation that the early history of life was formed on clay crystals, only subsequently being transferred to organic molecular chains.

[Perchless swallow. Human history of memes just an early segment of their learning curve?]

Money

"Money is like a sixth sense without which you cannot make a complete use of the other five" - W Somerset Maugham, *Of Human Bondage* ["Life is too short to do anything for oneself that one can pay others to do" - W Somerset Maugham, *The Summing Up* "As I take my shoes from the shoemaker, and my coat from the tailor, so I take my religion from the priest" - Oliver Goldsmith, quoted in Boswell, *Life of Johnson* (DQ)]

Organic life may almost be defined as patterns which have taken nucleic acid chains as their means of replication. By analogy, memes can provisionally be thought of as replicators which have taken vast chainings of human intentions as their means of replication - presupposing life just as life presupposes replicating molecules. However, while an individual intention necessarily has a psychological ingredient, a chaining of many intentions is not necessarily intentional - though it may be. This - the anonymous necessities of the social - is a problem I return to. First, however, I glance at some ways in which individual intentions can and do unknowingly bind together - money: law; crowds; and formal organisations.

If artefact-memes do not start from a common evolutionary substance - as life has, in large-self replicating molecular chains, varying and being differentially selected as they replicate - perhaps they may nonetheless have evolved, or be able to evolve, an analogous common substance? Something of this sort, I think, already exists, in the form of money. The differences - the external character of the common substance, and the reversed evolutionary ordering - correspond to the facts that while large carbon molecules and their macrostructures replicate themselves internally, from themselves, memes are replicated externally and by other memes (and by people). One - relatively late - result in their evolution has been the evolution, through exaptation, of a meme specialised in exploiting a particular niche: barter, leading into more generalised exchange.

One way of viewing life is as a vast set of interlocking mutually dependent routes for proliferating variant sequences of DNA. Similarly, a monetary economy consists of a vast set of intermeshed alternative pathways replicating and expanding money. In the first case the common basic replicator is a starting point, in the second it is a result, but the effect is somewhat the same. Being external and a relatively late product of evolution, the common replicator can also evolve to fulfil external functions - such as equilibration across the overall mass of value expansion. The adjustments this brings into play also tend to maximise the rate of expansion of the whole mass of money. {Footnote 78} Indeed macro-economics is, in the view of one influential school, simply artefactory production with diminishing marginal returns - only writ large.

Money is also central to one of the ways artefact-memes expand the mass of value - through accelerating, creating, surveying and filling new openings in the overall replicative structure. Biological life, originally equipped only with direct, exact replication plus occasional (random)

mutation, has had to evolve special, subsequent arrangements: speciation, to allow its ocean of genes to be divided into separate, specialising "gene pools", and, within many of those pools, sexual recombination to stir the genes more vigorously. Being superimposed on underlying, more fundamental, properties of the genotype which were selected for distinct reasons at earlier evolutionary phases, biological speciation and sex produce relatively awkward and slow-changing innovation mechanisms - compared, say, with some cultures, such as market economies. Viewed as a replicative mechanism money, partly through coming later in evolutionary development (insofar as we can make such comparisons across "zones"), also proves better at innovation. {Footnote 79}

When evolution works on intentions it tends to do so "backwards", selecting and thus modifying the intentions and expectations which issue from psychological processes via selection of means serving intentions further "down the line". An important class of social arrangements consists of "economic" meme-complexes which have the effect of shaping the intentions of some persons (slaves, workers, officials) in such ways that they meet the needs or desires - respond to the intentions - of others (e.g. owners, consumers, citizens etc) who are so remote they have never even heard of those to whom they respond. Individual humans are socialised and placed in their social classes partly by their minds being "engraved" (Dennett, check) by socialising memes which cause them to respond stereotypically to day-to-day memes.

Meeting the desires of some through the intentions of unrelated others is an important separation. It contrasts with the predominance of kin investment in many other species. {Footnote 80} Its effect is to attenuate the balance between effort and satisfaction that regulates the life of individuals among most higher animals: the fact, for example, that many animals cease foraging or predation once satiated. De-coupling the location - the human site - of the desire from the effort through which it is realized is what permits a social surplus to develop, and with it - together with other conditions, in particular the transmission of learned behaviour - luxury and invention.

But memes adapt intentions not only by expanding across more people the efforts they bring into play, but also by shaping expectations. "Ascetic" memes {Footnote 81}, or the restriction of expectations and the schooling in "deferred gratification" that goes on in the socialisation of every child, evolve as well as luxurious ones - and these stimulate their own forms of invention. These domestications of intention are also the work of memes - and memes which also often require of their human carriers/vehicles considerable effort in order to limit the consumer's calls on the efforts of others. The relation between asceticism - or luxury - for one person and the burden on others is often complex. As Gandhi was reminded by a follower, it cost a great deal of money to keep him in the poverty he had grown accustomed to. {Footnote 82} Conversely, even monarchists get drawn into debating whether the Royal Family provides value for money.

Asceticism of a kind can also be had by expanding the number of memes' consumers proportionately more than the total cost. The twentieth century electronic media do this spectacularly well, concentrating vast social resources on individual templates, which are then replicated at small or negligible marginal cost. Even the most elaborately designed templates, however, are often elaborations on ancient psychic equipment. The appetite for gossip about kin and familiars, which evolved as a key but high-cost - one-to-one - aid to inclusive fitness in our

ancestors' pre-literate (and pre-pecuniary) hunter-gatherer bands (as Barkow, AM, argues), did much to propel the telephonic revolution, and has been incorporated (with crucial modifications) into many of the most successful genres of television - not only chat shows, soaps and sitcoms but also, for example, global news.

Money is a crucial adaptation of such memes, not only in the general sense that the technologies have evolved within moneyed industrial societies, but in the nitty-gritty competition between programs. TV advertising sells on the basis of charges [CPM?]: numbers of viewers weighted by their disposable income.

Global culture is a function not only of money, but of "species typical" adaptations: the fact that humankind's genetic unity entails (as "evolutionary psychology" accurately points out (CT)) compelling unities of anatomical and psychic design. Nowadays "Nikes are worn by cannibals." [Check ref Twitchell]

[Section on trashing of taste, mass media and unit cost of hominid gossip (Barkow). Cost per thousand dollars (weighted sum): money as regulator of the most intangibles]

Work

One obverse of money's meshing together unlike, by connecting their like linkages, is an omnium gatherum notion of "work" as something detachable from the experience of the human animal who performs it. In reality the division of labour is a separation of lives:

"There is no greater modern illusion, even fraud, than the use of the single term work to cover what for some, as noted, is dreary, painful or socially demeaning and what for others is enjoyable, socially reputable and economically rewarding. Those who spend pleasant, well-compensated days say with emphasis that they have been "hard at work," thereby suppressing the notion that they are a favoured class. They are of course allowed to say that they enjoy their work, but it is presumed that such enjoyment is shared by any good worker. In a brief moment of truth, we speak, when sentencing criminals, of years at "hard labour". Otherwise we place a common gloss over what is agreeable and what, to a greater or lesser extent, is endured or suffered." (Galbraith, 1992, p 33)

Socialism shares the difference and consequent fiction. Haraszti (1977) came to think of workers and their managers in the "workers' state" as distinct species, partly co-inhabiting common space {Footnote 83}. From time to time social science fiction has projected a future in which the reproductive isolation of classes becomes (or is made) absolute and speciation occurs. {Footnote 84} But the differentiations could also, and perhaps better, be expressed in terms of differences among the species' of memes by which humans are domesticated. {Footnote 85}

The related point that the social organism becomes complex at the expense of individualism has often been made. Here is Mikhailovsky's essay on progress in [187?], attacking the paeans to industrialization of Herbert Spencer and the social Darwinists:

"If society makes a transition from homogeneity to heterogeneity, then the process of integration in the citizens which corresponds to this transition must proceed from heterogeneity to homogeneity. In short, individual progress and social evolution (on the model of organic evolution) are mutually exclusive, just as the evolution of organs and the evolution of the whole organism are mutually exclusive....In an organism it is the whole that experiences pain and pleasure, not the parts; in society it is the parts that experience pain and pleasure, not the whole" (quoted in Edie, Scanlon and Zeldin, II, 180-1)

Law

Law and property, as systematic means for modifying and redirecting the efforts of others, precede and underpin the emergence of money. Legal norms endure by replication. The origins of "justice" in the sense of fairness and impartiality lie less in moral considerations than in the evolution of legal and quasi-legal memes for the more efficient administration and operation of law. The operation of law goes far wider than the tiny minority of situations in which it is explicitly invoked or enforced; it regulates and circumscribes much of everyday life because legal memes evolve in such a way that they easily enter into the habits and motivation of most of the population, even where they do not crystallize as explicit awareness. The law acts as both efficient and final cause of law-governed behaviour, not so much because subjects select among their intentions to eliminate unlawful impulses, but because their intentions are formed already "engraved" by the extant legal memes. An important element in the design of legal memes is the jurisprudential principle that "A law is best the less it must be enforced", and the fact that temporary or local lawlessness (the breakdown of law and order) is identified with situations in which coercion comes into play as a means of regulating behaviour.

Modern legal systems have evolved to the point that they are administered by highly trained, socially and occupationally segregated, legal professions and judiciaries, themselves complexly internally differentiated. In reality ignorance of the detail of the law is the almost universal condition, an ocean of vagueness, dotted with human islands of professional competence. These islands perform the social function of "radiating" awareness of the legal structure through the population as a whole. For the structure of legal memes to act effectively and continue it must generate - or more exactly, perhaps, emanate - popular quasi-legal memes which can readily enter into the habits of the population as a whole. The legal fictions that knowledge of the law is general or that ignorance of the law is no excuse - is nowadays essential to the integrity of legal systems. It is reflected in other general, but more practical, maxims: that minor or unintentional breaches of the law are not subject to sanction, that legal reform and administration should aim at commonsense consistency etc. And it elicits specialised adaptations - compliance officers, legal departments etc - in complex legal personalities. Just as language acts not through particular points of application or by the seriatim utterance of words, but through providing a structure within which meanings are transmitted, law operates not through particular episodes of enforcement, but through the general dispositions within which law-regarding habits and intentions crystallize {Footnote 86}.

But awareness of what? The simple image of law as objective, or at least as texts on tablets, dissolves on closer examination. Law which is stated in broad, popular but definite terms on one skin of the onion is, seen in more detail, an effect of memetic consensus among specialists. Often

enough particular cases discover fissures in the consensus at one level, which must then be resolved by reconstruction into more detailed consensus, new memes embraced, so to say, in the legal profession or judiciary or particular segments of it. The common law notion that judges, aided by lawyers, discover a pre-existing law is recognized by those engaged in it as the necessary appearance it is: an appearance transmitted and made necessary by the requirement that laws survive by propagating themselves in a form securing broad compliance - a compliance which is itself a condition of law being nourished by the economic system.

In its developed form law, like money, acts as a permanently adapting and structuring framework of intentions shaping other intentions, acting through a continual flux of memes. Money and law each embed themselves in social relations as an apparent structure of transmitted values and rules. In each case the individual feels her or himself to be, and as a consequence really is, directed by institutions experienced as "things" (but with intentions). More closely examined, though, these things are relations, transmissions, interchanges among people - relations which persist and replicate themselves, both severally and as the complex wholes they build up into.

Their persistence and replication are strongly affected by natural selection, and consequently tend to evolve in their survival and propagation functions. They become, in the perceptions of individual humans - which is one of the most important things with cultural transmission - "reified", appearing as encrusted and coercive to the individual, human relationships transformed into things. And the thing for one individual is formed of the human relations of others.

{Footnote 87}

Law and legal memes are good examples of how natural individual selection among memes can produce effects - behaviour coordinating genetically unrelated individuals - which would require group selection to arise biologically. The legal meme with the greater capacity to replicate itself - principally by eliciting compliance - across the human group and over time is the one that tends to get selected.

Crowds

In moving from money to law we shifted from a type of complex meme with a more-or-less tangible expression to a type expressed in less tangible social institutions - a change, so to speak, in the staining and magnification employed for our sociological microscope. Let us continue to vary the optics. Consider the performances of individuals in two moving but intersecting crowds of rush-hour commuters as they cross the concourse of a rail terminal. Each individual is oriented towards their next turning point - the exit, the kiosk, or whatever - and walks towards it at a speed whose elastic upper and lower limits are set by average capacities.

Yet collisions are far fewer than for two streams of particles on similar routes at similar velocities without forces of mutual repulsion acting at a distance. Between the individuals composing the crowds there take place continual, rapid, unreflecting - in a sense microscopic - identification, classification and tracking of others, and an estimation and reassessment of their intentions, integrated with the subjects own continual adjustment and readjustment of her own pace, posture, gaze and intention. Each individual can be considered as radiating a continuous stream of memes, and as continually selecting and processing memes from others. This generates

interactions (of which the simplest is repulsion) between individuals and their intentions which are negligible at separations of more than a few meters, but are a markedly inverse function of distance at the lower ranges, so that near contact evokes a sort of reflex of recoil. Crowd behaviour as shaped by this meme-flux contains symbolic ingredients that differentiate it from herd behaviour. The moving, calculating commuter is continually recognising others according to symbolic and normative as well as physical-biological criteria. The symbolic criteria which come into play are those of the culture - of which the crowd forms a momentary agglomeration and concentration.

Norms

Dress and other accoutrements are among the most important of these. A currently-recognized uniform is more-or-less essential to interrupt or deflect the commuter stream. Even in Rome an individual dressed as a centurion is presumed to be on his way to a fancy dress party. One good measure of women's inequality with men is the effort a female uniform wearer must project to successfully steer the crowd. On the transit systems of San Francisco or Paris the white stick carried by the person with impaired sight serves (like a green light for her, and a red for others) as an instant symbolic signifier to leave additional margins of space and time, and causes others to adjust very rapidly the image they hold of the stick-wielder's visual field, state of knowledge, and intentions. The effect is both familiar and symbolic or cultural - the white stick is an effective modifier of crowd behaviour in New York, but is unintelligible among crowds where a different symbolism exists, or where people with seriously impaired sight seldom go, or go unescorted, in public, as in much of the Third World.

The effect is also familiar in the sense of being the almost effortless consequence of recognising a symbol, rather than the outcome of any chain of deduction from particular circumstances of the situation. In deductive logic thick glasses should evoke the same sort of response as the white stick, only perhaps less marked. In reality the meme flux has evolved rapid-symbolling routines through which wearers of glasses alone are assigned to the category normal, and those with white sticks are disabled. Disability is expressed symbolically in the white stick, or the exaggerated, "warding away" gestures used to usher a wheelchair user through the crowd.

The evidence of impairment or the appliance to compensate for it has become a symbol - a radiator of stereotypical memes to others. One advantage of the stereotyping is economy of effort - rapid recognition and avoidance. Receivers of such stereotypical memes are rewarded by a direct gain in symbolic status. The white stick affirms the sighted avoider as normal and at the same time gives him an opportunity - more, or less, ceremonious or fleeting, seized to an extent that time and personality determine - for a demonstration of status and chivalry in face of one of guaranteed lower status. {Footnote 88}

Earlier symbols of this sort had such functions even more explicitly. The tolling of the lepers bell, the beggars' stumps at the cathedral door, served to highlight one's own wholeness and salvation. Alms cemented the reassurance; the monetization of charity, as excoriated by Luther, grew from such everyday exchanges of status. Without the symbol the norm would scarcely exist. In Hitler Germany's the Star of David, or the pink triangle of homosexuality, were memes of warning, but also of reassurance. {Footnote 89} As with the segregation of women in the

mosque or synagogue, differences or supposed differences of biology are crystallized into memetic reaffirmations of humanity. But where the "minority" is a smaller proportion the psychological effect, to be general, must be correspondingly more intense. {Footnote 90}

In the anonymous, factory-dressed commuter crowd guarantees of relative status are all-too-scarce. The hunter-gatherer's anxious monitoring of self-vis-a-vis others for relativities in dominance flicks over a torrent of unintelligible, momentary others, negotiating a route through society like a smoke-signaler in the fog. Much of the crowd's suppressed tension arises from the fact that each of millions of individual subjects is simultaneously thirsting for sociability and dominance.

General clues - of age and personality, education and affluence, gender and motivation - exist, with their signals of inquiry and empathy, assertion and deference, and enter into the close-range interactions in mass society's crowds, generating the close-range "strong" forces. Up close the forces of repulsion among citizen-strangers are strong. One of the things the human mind is domesticated to do is negotiate the individual's route through a bombardment of normative claims, combining minute deftnesses of interaction with fine judgments of clearances and tolerances. In the crowd others are all potential animals or machines, animated but unfamiliar, in a potential human-jam, and uncertainty makes it necessary for psychology - and thence action - to expand the clearances. {Footnote 91}

The human crowd differs from common types of animal herd in other domesticated species, such as sheep, where physical contact and ricochets do not raise stress levels so much. {Footnote 92} The strength of close-up forces once human body-spaces overlap {Footnote 93} can be judged by the violence of the measures sometimes necessary to overcome them and pack the commuting atoms more densely. The Tokyo subway has special employees whose job it is to pack more people into the cars, squeezing bodies up against each other - and raising mute meme-exchange and repulsion to extraordinary intensities. In medieval towns, grown up round foot transit, those of high social status travelled with a retinue - "retainers" as much as body-guards - whose function was to buffer the protected individual against the continuous jostling of ordinary members of the crowds. The forces brought into play when crowds are obstructed soon overcome lightweight and hence symbolic inanimate barriers; the football crowd or demonstration must be held back with special retainers, whose powers of repulsion are amplified by special memes - the uniforms, drill and training of bodies of police.

Structuring the crowd: uniforms

The adoption of a uniform is a good example of memes achieving the group selection effect that genes cannot. Uniform memes emerge, like multi-celled organisms, only when simultaneously replicated on a fair scale - where more casual signals of status and function prove insufficient to maintain a coherent, lawful meme-flux ordering a crowd. {Footnote 94} Consider the differences between (a) two counter moving crowds of commuters flowing face to face into each other, and (b) two hostile battle formations of infantry engaging in hand-to-hand combat - the differences not only of overt behaviour but of moment-to-moment psychological adjustment. The multiple, more accidental attire which serves to orient the individual in the first case is insufficient in the

second. A basic memetic adaptation of military action until quite recently was the bold stereotyping of the other as enemy or friend, object of lethal assault or potentially fatal altruism. A bayonet is a memetic weapon. When the forces of uniforms and patriotism grow weak it no longer functions to order, becomes just "a weapon with a worker at each end".

Animals other than humans are innocent of war (as distinct from, say, group predation or mobbing), not just because they lack the technological memes but because they have insufficient differentiation and recognition of individuals, incapable of sustaining command - one centre, coordinating others against yet others. Command is also stereotyped for easy recognition and compliance: the officer's insignia; the regimental colours. In war officers' bright insignia designed for recognition by comrades of other ranks may - like the peacock's tail - render the wearer especially vulnerable (because he is recognisable by the enemy). In the trench warfare and massed assaults of the First World War officers' uniforms made them particular targets of small arms fire, and over time battle dress differentiation was reduced to the minimum which would enable recognition by one's own side at close range.

Crowds gather at different places for different purposes, practical and ritual. The same individuals who will patiently tolerate a mother weighed down with shopping and toddlers, or an old person fumbling with packets and change in a supermarket queue, would elbow the same individual aside if she attempted the quite different tempi of the city rush-hour. The promiscuous body contact of the Calcutta market place or the pilgrim horde at Lourdes would be downright offensive on the pavement of the Via Condotti or the Rue St Honore. Individual social clues are also important: indicators of higher socio-economic status - the Harrods carrier bag rather than one from Tesco - may purchase space through amplified avoidance. {Footnote 95}

Formal organisations

The anonymous, unstructured crowd of commuters' functions and flows by the continuous person-to-person transmission of memes. It is also a (less immediate) result of replication among many other types of meme: those of factory or bureaucracy; of suburbanization; of electrified means of communication and transport; of large-scale commercial and state organisation; of revolutions in information technology. Many of them involve the routine recognition, classification and use of other humans as predictable stereotypes - in the extreme, quasi- or virtual machines. Human minds (as Dennett has it) are engraved by memes to process other memes. Ease of recognition and use can give enormous replicative advantages to the meme complexes within which they function: the semi-skilled worker as a substitutable component of the assembly line; the post to be filled by the appropriate qualification; the lubricative effect of civic consciousness and civil rights in the crowd of citizen-voters-commuters; the orderly flow of the mass into office or Auschwitz.

There are, of course, also efficiency-penalties to substitution which override individuation, especially where group tasks are complex, have moving goals, or make stressful demands on cooperative skills. The hoplite phalanx was a major innovation in infantry tactics, not only because it fused bodies, shields, armour and weapons into an orderly, relatively safe array, but because it did this on such a scale that most of the young men of the phalanx, drawn from the same village or district, knew each other as individuals and comrades. Attic citizenship,

comradeship and eroticism in the phalanx aimed, by different means, at what the mass military schooling of Spartan education also sought; the integration of individual motives and impulses into machine-like mass action. {Footnote 96}

Formal organisations often find - by evolutionary trial and error - that they cannot dispense with the need for intimacy. At the tactical level modern military organization is a complex compromise between the dictates of equipment, unity of command, and training, battle hardening - and loyalty on the approximate scale of the hunter-gatherer group. The bureaucratic battle group cannot fully emancipate itself from its ancestry in the phalanx or posse. Troops may risk all for comrades where they would not put their lives on the line for commander, nation or fellow-citizens in the abstract. {Footnote 97} Similar considerations of scale and familiarity apply to the designed or traditional work crew, the surgical team, the school class, or the invisible college of academic specialisation. {Footnote 98} The family frequently collapses as the site of child care and socialisation, but when it does the state, saddled with infant citizens, can often do no better than reconstruct it.

Modern complex organisations are frequently built round explicit statements of intentions, mapped into organizational structures. Intentional change can then occur (in part) by linked modifications of goals and structures. Or it may occur - as our *homoousion* example (above, p) suggested - in more local, inexplicit ways. In all cases where intentions are transmitted between people *unintended* consequences of social action arise - it is just a matter of their nature and extent.

The case for memes

What do our examples suggest? Let me briefly make the case for the "meme's-eye view". Psychological and cultural phenomena form - that is what monism means - part of a seamless universe. As such, they can be understood from various points of view. What is most effective depends on what specific phenomena we want to understand and, equally important, on the means of understanding available to us from meme-evolution (history) up to date. To take examples from our present historical location: we can view the human world from the standpoint of physics and chemistry (for example, in dentistry or pharmacology); we can see it as one specialised type of molecular-patterning replication (as in biology); we can think of culture as the interactions of individual human organisms (as in anthropology or sociology). Or, I'm suggesting, we can think in terms of the natural history and evolution of memes, chiefly of meme-forms specialising in the direct and indirect "domestication" of human beings.

These standpoints do not exclude each other. They require occupational differentiation among humans, and they are thus, to a degree, separated from each other, but the barriers are neither waterproof nor fixed. On the contrary, to regard the universe as seamless means that among the tests applied in meme-selection is the requirement (itself evolved as a complex meme) for logical consistency between the memes employed by different standpoints.

Looking at the world in meme terms is not new. History does it insofar as it seeks to be explanatory, or populates its narrative with ages, classes, styles etc. But its treatment has often been casual, anecdotal - or, worse, narrowly human-focused and pragmatic, failing to see the

memes for the people. The second part of my case for a (more systematic) meme's eye view is the claim that the study of memes can be effectively developed if it borrows models and insights from the existing natural sciences, particularly from evolutionary biology.

When we try to understand why the commuter crowd makes space round the man with the white stick, why the audience rises for the national anthem but weeps for the aria, why wife and husband, corporation and customer, TV and viewer, trick and treat each other as they do, why the bull and the Bolshevik see red so differently, or how rival personal computers compete, thinking in terms of the natural history and evolution of memes can be useful. This is not to deny that humans (or their sticks) consist of agglomerations of atoms and tissues, that they grow under the control of nucleic acids, or that speech and music accord with the physics of vibrating bodies, but just to suggest that a meme's eye view may have a distinctive purchase on these things.

Meme memes

This brings me to the third component of my case for memes, which is that of relative advantage. When we argue about ideas and theories one of the things we are doing is selective breeding of memes. And in defence of Dawkins' meme memes it can be said, at the very least, that their immediate competitors - the social and psychological sciences - have not recently shown anything like the pace of successful adaptation of natural science memes. There is, so to speak, a niche waiting to be inhabited. Insofar as explanatory power is an important criterion of selection, the environment for meme-theory looks a favourable and under populated one.

One objection to placing too many hopes in meme-theory may be the underdevelopment of psychology. We are still far short of understanding the macro- and micro-mechanics by which memes "parasitise" humans. But we can draw some comfort from the history of biology. Darwin, Wallace and their early followers were able to sketch an essentially accurate theory of natural selection even though they did not understand the physical machinery of heredity and variation, were unaware of Mendel's genetics, and were inclined to the false view that some naturally acquired characteristics could be inherited. They were able to develop their theory by drawing on what was available - evidence from fossils and geology, work on biological classification and the study of species' distributions, embryology, and the experience of commercial breeders and growers. Today, the study of human culture and psychology is not really short on empirical evidence; the problem is to locate it within unifying principles. Unfortunately meme-evolution has equipped us with powerful inhibitions against doing this in its differentiation of academic and scientific specialisation.

One universe

Our universe can be thought of as selected selective processes favouring patterns that endure. {Footnote 99} In terrestrial conditions "elementary" wave-particles combine in various configurations - the more stable of which form nuclei. Among nuclei, some few dozens are stable enough that (after much meme-evolution) we now identify them as isotopes of distinct elements. The longer-lived among them - together with their longer-lived fission-products - form the atomic "stuff" of our world. Their electron clouds form - according to their total charge - more or less stable configurations. The more stable are inert elements; the less stable are prone to

bind to others as compound molecules. At low momenta many molecules enter into crystal lattices; several possess more than one stable lattice pattern, and which crystal structure spreads may depend (among other things) on which is there to be replicated in the first place {Footnote 100}.

[Can Dawkins' (in *The Extended Phenotype*) be heard as saying that matter is simply the occurrence of successful forms? See as quoted in Smith, *Genes, Sex and Evolution*, p 106 ff]] Notice that natural selection does not require replication - at least, not in any strict or narrow sense. Water's action on granite separates the quartz grains from feldspar and mica, preserves and transports them, and organises them, finely graded, on beaches (Van Valen 1989).

Carbon and oxygen, though, bind with some other elements in a large variety of extended molecules. Among these, some have the particular property, in a suitable chemical environment - such as exists within a cell, for example - of being able to serve as templates for the repeated assemblage of complex chains from shorter chains free in a water solution around them; their synthesis-sequences, acting together, both feed upon and generate the intracellular food in which they live. One in particular - ribonucleic acid - has the striking property of serving as its own template. Within cell nuclei it forms double chains, parallel spirals, with two types of asymmetric "linkages", each of which has two "sides" and consequently two orientations - a total of four possible types of link making up chains of indefinite length and complexity. In cell division the double spiral peels apart, each side immediately replicating the double chain by binding to free bases in the soup.

While all cells employ this basic chemical machinery for replication, the life cycles of daughter cells also depend on the cell's environment. Cells inherit characteristics acquired from the environment; the developmental programs of a genome provide for cells to produce offspring whose traits are determined by the parent's acquired characteristics - that is, for "cultural" transmission between cells to affect cell replication.

Some cells restrict their environment in their favour by cohabiting as groupings of several cells. Some among these further improve things by evolving patterns of specialising differentiation among themselves - organisms. Their coherence and structure derive from their cells' common ancestry and the presence of an identical development program laid down by the precise pattern of DNA replicated throughout each organism's cell nuclei. Because this provides the "atomic" basis of organisms' coherence, replicated in this infinitely repeatable way, all organisms' life cycles, no matter how differentiated and elaborate, involve a single-celled reproductive stage, which has to contain the overall development program for the organism.

The sub-program controlling the cell's own division and replication, however, must be rather sensitively attuned to the mother cell's environment and history if it is to produce a variety of appropriate types of daughter cells at the right times. "Copying errors" occur. In most cases these are lethal to the daughter cell, and excretion disposes of her remains. Occasionally, though, the copying error produces replicatively viable daughters, or even cells with a replicative advantage relative to normal cells, such as those which form tumors. Sometimes errors arise at the single-cell reproductive stage, and very occasionally these are neither lethal nor disadvantageous for the offspring, but advantageous.

We can think of these replication processes in terms of DNA sequences or of "genes" - which interconnect but don't necessarily correspond to contiguous sections of DNA. Although genes are notional in a sense that contiguous DNA sections are not (or less so) biologists find that thinking in gene terms can have considerable advantages. {Footnote 101}

Memes and the evolution of psyches

"We keep passing unseen through little moments of other people's lives" - Robert Pirsig, *Zen and the Art of Motorcycle Maintenance*.

Species have distinctive behaviours as well as structural adaptations. Many "extended phenotypes" (Dawkins 1982) have behaviours which use other species and/or external materials external structures as functional parts of their life cycles: parasitism/predation, nests, burrows, caches, colonies. Many have life cycles incorporating substantial "parental (kin, sibling) investment" in their offspring beyond their single cell reproductive stage - transferring resources to the offspring's physical structures or environment, or to form both structures and behaviours. {Footnote 102} In humans artefact making and investment in behaviour combine to produce particularly elaborate results. Lengthy childhood dependency develops humans ready to replicate other humans' intentions in extremely flexible and therefore powerful ways.

Memes and humans use other humans as tools, and these walking, talking "tools" themselves use other human tools, chaining them together (through language, shared artefacts, rituals, law etc) in sequences of connected intentions. {Footnote 103} Division of the meme's labour doesn't require this particular human tool, just one suitably adapted. Theatre, for example, turns on the tension between this and the irreducibility of the tool's own experience: mistaken identity with all its comic possibilities; or a human consumed in tragedy's realisation.

We can think of chainings of intentions in terms of human psychologies and of humans' minds and actions. Or we can think of them as phenomena in their own right - memes. Memes grow and replicate through enculturing, influencing and organising humans, somewhat as genomes do through growing proteins and nucleic acids. The core of the case for the meme's eye view is pragmatic: that it can help us understand culture better. We can think of the white stick, or the aria, in terms of the interactions of molecules, or of the interplay of human individuals. But it can be less cumbersome to think in terms of concepts more tailor made for the purpose. When evolutionary biologists argue through their ideas on aging, seed dispersion, altruism or immune systems in terms of genes none of them dispute that these things could in principle be described in molecular terms. But between the "in principle" and today's specialised humans, organised as they historically are with the artefacts they possess, there is a large gap. The idea of a gene helps reduce it a little - so meme evolution tends to adopt it. An important element of the case for memes about memes is that they can do likewise with culture.

"It is natural for geneticists and evolutionary biologists to hope that their disciplines will throw new light on the human condition, and equally natural for social scientists to resist the threatened takeover" - John Maynard Smith, 1988, p86.

Thinking in terms of memes can complement "evolutionary psychology": the study of human psychological adaptations incorporated in our species in its genetic past. The success of a popular food (or a patent cold cure) may be understood as the outcome of our ancestors' liking for salt or sweetness at a time when these were rarities and hominids' reproductive success was affected by preferences for them. It may be understood through the neuropharmacology of our responses to sugars or salt. But it may also be understood as the evolution of families of foodstuff-memes: domesticable food-grains, or beef burgers (involving the co-domestication of cows, consumers and coins). Or it may be understood in terms of memes linked to the "reproductive" cycles of the foodstuff-memes: advertising, or factory farming. Or (as Dawkins argues in "the dissolution of the organism") it may be seen as part of larger self-replicative cycles by infective organisms. {Footnote 104} The explanations each have their own limits, and they overlap. The important principle is that they should be consistent with each other or - apart from anything else - fuller integration will be impossible.

Thinking in terms of memes can help repair - or, at least, supplement - one of "evolutionary psychology's" limitations. This is its tendency to work with a model of human "psychological architecture" in which the most "basic" structural components are humanly universal, "species typical" psychological adaptations to a Pleistocene environment of evolutionary adaptedness. Culturally specific phenomena - language, diet, dress - tend to be explained only in part. Thinking in terms of memes can supplement "evolutionary psychology".

Historically, "evolutionary psychology" has evolved in competition with that important current in nineteenth and twentieth century thought which asserts that cultural phenomena can only have cultural explanations. {Footnote 105} The anthropologist Clifford Geertz, for example, seems almost to de-psychologise individual thought:

"Human thought is basically both social and public - ... its natural habitat is the house yard, the marketplace and the town square. Thinking consists not of "happenings in the head" (though happenings there and elsewhere are necessary for it to occur) but of a traffic in what has been called.... Significant symbols, words for the most part..." (Geertz 1973, p 45) {Footnote 106}.

Others have gone further, arguing that the specifics of human biotic evolution have no relevance to understanding the evolution of cultural entities. {Footnote 107} "Evolutionary psychology" castigates any such "Standard Social Science Model" (SSSM) (at least insofar as it segregates psychology from human evolution) and rejects the idea that newborn human psyches are infinitely malleable by their cultural upbringing. It seeks to restore evolved human psychology as the missing link between natural selection and social action.

Much of anthropology is indeed, as evolutionary psychologists complain, dismissive of psychological explanation. Marvin Harris' Cultural Materialism (a common textbook) roundly declares that "the human intuition concerning the priority of thought over behaviour is worth just about as much as the human intuition that the earth is flat" (Harris, 1979, 60). But there is also truth in Geertz' point. Social scientists could certainly use more effective tools to understand the interpersonal "traffic in significant symbols".

"Evolutionary psychologists" criticisms of the SSSM and their efforts to reinstate psychology converge with some lines of critique from within social theory. Moscovici (1993), for example, writes of sociology's inhibitions against "psychologism" as symptomatic:

"The segregation of the psychological from the social has become institutionalized in our culture. Though independent of any critical reason, this segregation resists every kind of criticism. Those who risk calling this into question come up against censorship and, to begin with, censorship of themselves" (Moscovici, 1993, p11) {Footnote 108}

The way forward, in Moscovici's opinion, lies in a double movement: to investigate the nature and sources of this disease-taboo, and to rescue from it, and hence develop, the flawed insights of social science. Like natural selection, he starts from where it's at, and tries out variants: on Durkheim's image of religion, Weber's views on Protestantism and charisma, and (his particular favourite) Simmel's account of money. {Footnote 109}

There is, I think, some parallel between the individual's Cheshire-cat like tendency to dissolve among practices and values in social science, and the difficulty in biology of pinning the organism down - of separating it out definitely enough from its environment to take it "for granted". Just as one cannot fully visualise a spider bereft of its web, one cannot visualise an individual human, island-like, in abstraction from the values and activities of the society s/he forms part of.

Social order and social surplus

Having hazarded such large claims for a meme's eye view I should also suggest ways in which they might - one day, perhaps - be realized. I end, therefore, by suggesting a few ways that memes might help with a central problem-area of social theory - understanding social order and social surplus.

This can be approached from various directions. The possibility of viewing the social surplus as a whole - and consequently as accessible to alternative uses, or redistribution - is a relatively modern one. It has come about with the monetization of society - that is, the predominance in social life of a single numeraire - money - which invites and demands humans to compare things in a purely quantitative sense: between things, between people, between societies, between periods in time.

Thus the problem of a social surplus - or of the net social product - crops up in a variety of ways in modern political economy. {Footnote 110} We can spy the problem in paradoxes of measurement and definition. {Footnote 111} The relative scale and growth of national economies are compared using measures of national income: gross national product (or income) per head, computed from information about aggregate money flows. But what counts as economic production and what counts (i.e. does not get counted) as nature's bounty is to a degree arbitrary. And the links between national income and human welfare are complex.

For example: Thais are poorer than Britons. By how much must Thai national income per head grow for them to "catch up" with Britain? National income statistics for Britain include a

substantial element for domestic heating. This increases when the winter is cold or the price of oil rises. Heating expenditures for Thailand are much lower. How far should Thai national income statistics be adjusted upwards to allow for its more agreeable climate?

Or: take state expenditure on pensions in developed economies. Where, previously, old people would have lived their closing years as dependents in an extended family, the state now taxes workers and pays non workers, who in turn spend independently, consequently leaving their trace in national income statistics. The circuits of money are amplified, incorporating what was previously hidden in the family. How far is the redistribution brought about by pensions also an expansion of income?

If, in addition, old people live longer, the total national income must be distributed among more recipients, providing less per head. The notional equality of citizenship injects population increase with similar paradoxes: shall "we" be happier because there are more of us, or because we are older and wiser, or the reverse? What if the price of more protracted isolation and poverty in retirement is more monotonous working lives?

Or take the fast food revolution. Instead of obtaining noodles, water, vegetables etc for a few pence, and cooking them at home, families now get takeaway meals (or have pizzas delivered) at much greater cost. Time thus saved is devoted (in part) to watching television; as a consequence family dining tables and family meals have disappeared in many homes. How do such changes show up in national income statistics? {Footnote 112}

In fact, like biologists, economists took some time to settle down with a model of the economy as a whole seen as the circulation and replication of one common substance: money. So-called neoclassical economic theory took shape in the late nineteenth century from an older tradition which sought to analyse economic life as interactions among qualitatively disparate production factors. {Footnote 113} In contrast, for neoclassical economics, the same basic principle of adjustment governs the markets for all particular commodities (pins, cotton, labour, bank debts, and reputations). {Footnote 114} Price varies negatively with supply (the commodity's price rises as supply falls), but positively with demand (the commodity's price falls as demand falls). The adjustment of prices, and consequently of the patterns of circulation of money, are the work of a "hidden hand" continually pursuing equilibrium.

Neoclassical economics applies the same picture to economies as a whole: aggregate values of "labour" and "capital" combine to produce "output". If the amount of capital per worker increases the rate of profit falls. Profitability serves as the "price" of capital, adjusting its quantity until the average entrepreneur feels no impulse either to invest or to dispose of capital. And - this is the beauty of the model - in doing so, and by the same token, the adjustment of the rate of profit determines distribution: how - in the simplest models - national income is distributed between profits and wages. {Footnote 115}

Think back to the baked bean cannery. The common numeraire, money (the economists' nucleic acid) is essential to this model - not only in theory, but in reality. It is the only thing that allows us - workers, businesspersons, consumers - to calculate aggregate amounts of wage, capital, profit etc. For in reality the capital of an economy - indeed, often that of a single plant - consists of a mixture of equipment doing different things, by differing technical means, worn out to

varying degrees by use and by age, and maintained in varying states of repair and partial renewal. And all that equipment is the product of past activity, using both similar and different equipment, and so on ad infinitum. Some common numeraire is necessary to add the variety together across heterogeneity and time; without it they remain incommensurable.

Aggregate economic production

Describing the freezing-fossilizations effects of price in production economists are easily driven to metaphor. Trying to capture capital's combination of malleability and fixity they have spoken of "fossils" - and also of butter, toffee, putty, clay, meccano pieces, and so on. What the metaphors have in common is the attempt to simplify, and thus capture, relations across sectors, across space and - especially - across time, the sense in which exchangeable resources carry ("fossilized") within them the history of past resource use, and the part played by past technologies and prices in setting the price of new-made artefacts. {Footnote 116}

Relative rates of profit - that is, relative rates of replication of capital - act to extinguish technically superseded capital and replace it with - selected - capital that incorporates more efficient innovations. That is to say, the rate of profit plays, in economic life, something of the part of "fitness" in population biology.

Paradox

There is a paradox that can be derived from the technical analyses. On the premise that capital is homogenous, the rate of profit may be a rising function of the aggregate value of capital. {Footnote 117} If an increased quantity of capital is associated with an increased rate of profit, what has become of the mechanism through which profit served as the "price" of capital, rationing its supply? {Footnote 118} The treatment of capital as homogenous is crucial to the paradox. It involves treating all particular capitals, different as they are in their technical natures, their ages, and the degree to which they are worn out, as though they were commensurable in a common numeraire. As time goes by, individual items of capital equipment (say, machine tools) change their relative values. They do so for mixtures of reasons. They wear out with use and with age. The prices of the things they are used to make (pistons), or could be used to make (artillery shells), changes (sometimes rapidly). Technical progress occurs, so that even unused machine tools which were made in the past are devalued relative to up-to-date ones. The average amount of capital used (or the total number of machine tools) per worker in the economy changes - in the course, for example, of industrialization.

Distribution affects prices. The proportion of profits going into savings rather than consumption is, in general, higher than the proportion of wages. Thus an increase in real wages - for example, due to strikes, or elections - can change the overall distribution of income between consumption and savings and thence - through a variety of routes - the relative values of different stocks of capital.

The common numeraire serves, through adjustments of prices, to homogenize all these differences into an aggregate value of capital. The paradox of "double switching" (the fact that an increase in the aggregate value of capital may be consistent with an increase in its rate of

profit) can arise because changes in one segment of the capital stock can affect values in other segments.

Organic life and memetic life

In organic life, however, segregation sets tighter limits. Finite organisms, reproduction, speciation, and the isolation of germ from soma constrain gene flow into distinct channels, which interact through relative rates of population growth. For much population biology measures of quantity (population) and increase of quantity over time (population growth) are (1) conveniently provided by the counting of organisms and (2) subdivided by speciation into distinct gene pools. Speciation largely spares population biology the paradoxes encountered in economics (which may, perhaps, be defined as that part of social science from which organisms have been most thoroughly removed). Reproductively separated populations of distinct organisms leave population numbers and growth rates - measurable essentially by counting - as the primary objects of analysis. For many purposes the analysis of marginal variations in rates of population change provides a framework which is free of paradox. {Footnote 119} {Footnote 120}

In certain senses organic life does produce an overall "surplus". What emerges over evolutionary time is an increasing number of organisms and species, of increasing complexity, and themselves organised in increasingly diverse and complex ecologies. It is hard to state this point so that nature's increasing roundaboutness could be compared in any rigorous (read, purely formal or quantitative) manner across time or lineage (though it is reflected in an interesting literary tradition on nature's unfunctional, irrational bounty, as well as in our scientific knowledge of the history of the biosphere to date). This difficulty of stating the process is the obverse of the absence of any universal numeraire - like money or value in economic life - which would allow us to compute a net product or surplus across all the diversity.

The difficulties are not only literary. Biology is concerned with maximization of fitness. But what exactly gets maximised, by what, and over what time scale? Maximising population is not the same as maximising population increase. Both are different from maximising the improbability of extinction. For some life forms the definition of individual organisms, and the borderline separating growth from reproduction, is less distinct than for others. Living longer and getting more massive may be relatively more advantageous than producing more members of the next generation. Speciation emerges from reproductive separation. {Footnote 121} As Van Valen (1989, p3) points out, if there is a consensus definition of fitness in population genetics, it is something like the *expected "relative number of individual offspring in the next generation of the population"*. But, as he goes on to show, all eight of the italicized terms are problematic. {Footnote 122}

If the reproduction of individuals is taken as central perhaps the closest analogues for organisms are found in self-reproducing cultures. But memes transfer far more freely than genes, and, consequently, if cultures resemble organisms, they are organisms among which species are extremely fuzzy, hybridization is rampant, and one can make no clear separation between nutrition and sex.

Or, to put the matter in social terms, the very free interchange of memes between cultures means that the evolution of cultures is a process in which latecomers can frequently and easily reap the advantages of backwardness.

Wants and needs, variations and adaptations

A similar parallel and limitations emerge from the distinction between needs and wants, conditions and preferences. A necessary - not sufficient - condition for us to perceive a social system as producing a net surplus is that it has production or activity over and above that involved in its own simple reproduction. The existence of a surplus is what brings the potential for dynamism into the system; without it it would continue as it is. {Footnote 123} But a fundamental problem in social science is that phenomena that emerge, as variants, in response to wants - forms of decoration, exchanges of gifts, conspicuous consumption, ritual performances, potlatches and puberty rites - then get selected as adaptations, embodied in the people and embodied in the culture. They get promoted from wants to needs, from preferences or tastes occasionally indulged, to parts of the social arrangements which must be systematically reproduced. And they then, in later evolution, come to form part of structures on which further adaptations become - so to speak, by further elongation of the embryo - embodied in their turn. {Footnote 124} If the rituals of social order, for example, are omitted or collapse in modern industrialized societies, the society passes into non-stable or non-reproducing conditions - revolution.

There are, I want to suggest, real advantages in seeing the embodying of preferences as the evolution of meme adaptations, compared with other frameworks, such as social functionalism. It helps us see the limited but real sense in which the social can be treated as *sui generis*. Consider ways in which social institutions - marriage, or money, for example - elicit loyalty or compliance from individuals. Social institutions are memes, but it strains matters somewhat to think of them as being imitated or copied from individual mind (or brain) to individual mind - as Dawkins describes a snatch of tune, or a line of text, as being copied. The point is not whether we are or are not aware of social institutions, but of how we - we, in general, that is - regard them, how we poise ourselves in relation to them.

Successful and enduring social institutions are often ones that appear to us to preexist ourselves as individuals, to exist as things rather than to consist merely in the behaviour of individuals - that is, the institutions succeed by becoming "reified". They may also become successful by exciting our emotions (of fear, shame, attachment etc). One of the ways they may do this is by resembling or mimicking other memes to which we have already developed such responses. Another, closely related, way is by exploiting the already-in-place attitude configurations of typical or common personalities - that is, personalities common within the culture.

As a summary of meme replication, copying or "imitation" is too narrow. It is not that the bachelor or the adulterer have not imitated the marriage meme in their minds, even less that the bank robber's (or the debtor's) brain lacks copies of money memes. Rather the memes in question have failed to elicit the usual compliance in these exceptional cases. And as the exceptions become more common, they exert increased pressure for variants of the social institution which achieve greater compliance to emerge and proliferate (serial monogamy, credit cards). Shifts in

the relative extents to which social institutions command compliance are very often the outcomes of highly complex interactions and adjustments between social institutions: the co-evolution of such memes in the course of social history. The relations between them range from direct competition to dependent symbiosis.

It is not only that the behaviour of individual people constitutes social institutions. People are also socialised so that (most of them) reinforce (most of their) enduring institutions. And people are historically specific. It is not that my image of my marriage or my credit card was or was not present in this or that hunter-gatherer; the possibility just doesn't arise; even to try and visualise it is a "category mistake"; it is incoherent with the rest of her or his personality. And, in turn, the historical (evolutionary) specificity of personality types is formed by the institutions through which they are socialised. Those institutions (family, school, peer group) select and combine personality traits (and some traits of physique) into individuals in restrictive sets of ways; some do end up outside the boundaries of what is "normal", but deviants are the exception, not the rule. And, crucially, socialisation uses the norms as templates of social and psychological reproduction. Deviants crop up in every generation, but by and large they are excluded from or neutralized by the social institutions most directly concerned with social and psychological reproduction.

Institutions and personalities

Social institutions and personalities thus co-evolve. This is, perhaps, what historians of the Annales School are referring to when they argue that history is not only the history of institutions but also that of "mentalities". It also has something in common with Thorsten Veblen's view of social institutions as formed by slowly evolving patterns of habit. {Footnote 125}

We may think, perhaps, of an analogy with the gene pools of two intimately dependent organisms - say, a flower pollinated by a single insect, which pollinates only that flower. Over time the gene pools of the two populations interact, but not directly. The interface (that is, the configuration of the *other* gene pool) changes over time and, at any particular moment, shapes the selection pressures operative in its complementary gene pool.

In fact the matter is more complicated, and it is a metaphor to speak of a gene "pool". Genes are not freely-floating candidates for recombination. Rather possible variants on the genome notionally coexist in a pool of alternative sequences. Certain common structures coded for within genomes and pools (organs and other adaptations, that is features universal to the species) form rules ("dams") restricting the channels in which combinations can form and move. {Footnote 126}

As far as our parallel with social institutions and personalities are concerned, we may think of the interface between the pools as separating the objective social (institutional) world from the subjective (psychological) world of a social order. The precise lie of the membrane is affected by the adaptations on each side of it, and this shaping, in turn, influences reproductive success on each side. The current array of institutions corresponds to currently "normal" types and ranges of personality. Important comparisons of anthropology (and much of utopian thought) revolve around the fact that personality traits and combinations that may be socially integrated within one system of institutions can be ferociously deviant if transplanted into another. All cultures

consist of mixtures of personalities, but the range and the mixture vary enormously from culture to culture. {Footnote 127}

Personality is itself a meme complex, of a particular type - relatively "primitive" in terms of the overall evolution of human-parasitizing and human-domesticating memes. Although the specific personalities of long-dead individuals may leave only very scant traces, we are able to observe remnants of the importance of animist thinking and forms of comprehension in the earlier intellectual and technological history of humankind - that is, generally speaking, in societies where recent meme-evolution has been slower. Today's "scientific", self-conscious separations between the human, the living, and the non-living result from developments which started in animal consciousness. Language allowed generalizations about the world to be exchanged, elaborated, preserved and refined, but these long remained expressed in the vocabulary of human personality.

Development of personality

In fact an individual's personality is not one, but many. It develops over time, in conjunction with physical maturation: Piaget and Freud's work represented attempts to give systematic accounts of, respectively, cognitive and affective aspects of the process. Ontogenetic development combines with the acquisition of features from the social and material environment. Some of these are universal in the culture, or so nearly so that they are the culture-typical analogues of genetic adaptations: language, literacy, infant mutilation, beliefs in enduring personality, the viability of money, or the deity. Entering as they do into the formation of virtually all personalities such features seem to humans to be natural and inevitable features of their world; only from outside the culture can they be perceived as memes which have evolved.

But even at one moment in time individual personality is manifold. People navigate their lives with reference to - indeed by means of - at least three types of personal image: how they see themselves, how others see them, and how they wish others to see them. These overlap but never entirely coincide. The development of social institutions goes hand in hand with that of a generalised Other, personifying the expectations and values embodied in institutions - an Other which elicits normality and gives definition to status. Insofar as status is the outcome of individual action rather than of ascription, the most important, and intimate, selective jostling is not that between corporeal individuals but that which takes place between the self's own self-memes or self-images.

Status

Barkow () describes the outcomes of such processes, from the outside, in terms of status or prestige:

"Our folk wisdom speaks of the young person "discovering" who he or she really is, much as the sculptor may "discover" the figure nascent in the stone. In terms of the present theoretical framework, however, the adolescent is actually seeking to determine which social and categorical physically present and physically absent groups will accept him or her, and whether he or she wishes to be accepted by them... [T]here is a weighing of how high the group or

category itself is, versus how high one is likely to rise within the group or category, a size-of-puddle vs. size-of-frog calculation." (Barkow, Darwin, Sex Status, 198)

In hierarchical, narrative societies memory elongates status as reputation, from the infant gloater's "Naahnaahnahnaah!" to the peacock-parade of academic dress. The jostlings between selves, between frogs (or princes), and between meme-pools or -puddles exert various selective pressures: between genes (sociobiology and evolutionary psychology), between people/frogs, and between the categories (sizes and puddles) in terms of which people see themselves and relate themselves to others.

Status, surplus, variety

"What makes equality so difficult is that we only want it with our superiors" - Henri Becque
Contemporary status goes far beyond local jostling in pools. Baumann defines the scarce resource of postmodern society as public attention. Andy Warhol made much the same point: "In the future, everyone will be famous for fifteen minutes." The point can be re-phrased in our terms, and generalised: for memes to secure attention, they must differentiate themselves from existing memes with which subjects are familiar, they must continually innovate - and they must innovate so as to make an impact relative to the patterns of variety and innovation with which subjects are familiar. {Footnote 128}

There is an obverse effect, arising from the limits of meme's human vehicles: for many things to achieve their quantum of public attention, the attention of most individuals must attend to an increasing variety of things and styles, switching with increasing rapidity among them: postmodernism's well-known fracturing of the psyche.

There are also, however, strong selective pressures on memes favouring rapid recognition. What the attention of the individual's psyche largely gets fractured among are stereotypes: signs, gestures, expressions, styles, motifs, brands, logos, themes, leaders, stars. The popularity of simplified stereotypes is detectable even in areas which make the most strenuous efforts to avoid oversimplification and multiply distinctions - such as academic specialisms. It is felt so widely because it is just one general facet of a pressure which affects all intellectual activity by finite or human beings: the pressure to economize on effort and time, working through differentiation between memes.

The competition among memes for public attention also works through to modify the processes from which they issue. It is a commonplace that life provides materials for art, but the reverse effect is also rather general. Litigation, for example, is a form of spectacle, and this has shaped its development. In Greek city-states amphitheatres were law courts, staged dramas, religious ceremonies and funerals, and served as places of public assembly and debate. The core of the curriculum in the education of a Roman gentleman was rhetoric, with its conventional forms of presentation and persuasion. In adversarial legal systems lawyers' success can be as strongly affected by their theatrical skills as by their legal competences - and these skills are learned from TV as well as fellow-professionals. The judge who condemns the felon to twenty years is in the same moment also pronouncing his "sound bite".

Simple replication of a complex system necessarily involves the reproduction of a "surplus", and part of this surplus gets applied to innovation (if it didn't, the system could not have arrived at its complexity). In organic life the surplus provides the elbow room for "wasteful" innovation, change, and the evolution of functional development (including functions which amplify variation, such as sexual recombination, or, like speciation, "focus" its effects). The same is true for memes, with the difference that variation is not entirely random, but partly intentional.

Chainings of intentions: memes in many heads

Happy the hare at morning, for she cannot read The Hunter's waking thoughts. - WH Auden and Christopher Isherwood, *The Dog Beneath the Skin*.

The impressive achievements of memes arise from chaining us and our intentions together in complex and extremely flexible ways. It is not only humans that use other humans as walking, talking feeling tools - so do memes. This raises the interesting question where "human" intentions actually reside - in individuals, institutions, processes - or (for example) memories or moods.

It also returns us to the question of memes which are too large and/or complex to fit in one mind. This is the obverse of the specialisation and academic division of knowledge, and of functional but incomprehensible artefacts, discussed above. Nowadays this applies to many physical artefacts. A modern airliner is produced in several hundred near-identical versions, with an airframe built on a common template. The "idea" of the airliner - as the basis for a machine which can actually fly - cannot be fitted into less than thousands of minds with specialist skills. It does so by having each of them address a limited, local design problem safe in the knowledge that others, with other skills, will resolve the knock-on problems to which their decisions give rise. This finely-structured bonding of many minds and intentions doesn't occur spontaneously: on the contrary a rising proportion of human labour time is concerned with coordinating others' intentions, coordinating the coordinators, and so on. Much the same is true of a modern motion picture, or of the sophisticated knowledge about the human body distributed through a hospital.

It is over simple to think of complex memes as "leaping" from mind to mind. Bits of them may do so, as one specialist replaces another, but it may often be better to think of large memes slowly migrating or "staining" their way across people, across materials and across institutions. But this image does violence to memes' coherence. We need to allow both for the extended, cellular, character of complex memes, the fact that they replicate themselves bit by bit, and their unities of function or intention. Like the seventeenth century axe, whose blade was replaced in the eighteenth century and whose haft was replaced in the nineteenth, memes can remain one implement though all their parts may be substituted. This is also part of the appeal of organic metaphors.

Conversely, when individual humans relocate, only some of the memes that inhere in them are "portable". The knowledge of a complex organisation's methods, procedures and habits which is "en-gorged" in its management and other staff. It is not simply that much of it is specific to the organisation in which it has grown, in the way that an individual organism's biographical history is specific. It is also that much of it - like the airliner - cannot be competently articulated by one

individual, but exists in the organization's traditions and culture. Collective "management buy-outs" express (among other things) the extent to which such context-bound knowledge is significant.

"Portability" is of the essence in education. Separating the processes of replicating and assembling skills from their application "for real" brings many advantages, especially in permitting the development of new, more elaborate and more powerful skills - analogous to the new horizons for technology opened up by industrialization.

One result is that the development of education itself involves self-referring and thus potentially "runaway" elements. All internally differentiated systems of education build on skills previously acquired. Example of language (learnt as dependent child - ambiguity of "childhood dependency"). Part of education is quality control within production - testing out skills acquired already. Ergo selective pressures exist for the development of intermediate skills per se - and all skills are potentially intermediate. The peacock's train is an adaptation for inseminating peahens with preferences for longer trains. Similarly, education systems develop adaptations promoting the transfer and proliferation of memes. And education systems are not only producers of skills, but major users of them. They thus harbour strong "chreodic" tendencies (Waddington 1972) - to get locked into paths of development once established. These cause continual frictions with the demands upon education to serve life, work, the economy etc.

[One habit education develops is measuring achievement against purposes: Education for what? Vain effort to subordinate ed to life - better to see ed as part of life's self-elaboration. Education of tastes, self-knowledge, how to play in the orchestra of our selves more beautifully, more economically, etc]

[Life as pressure to convert ends into means (i.e. to further elaborate ends). Explanation in terms of function. Problem: potential means include people. Problems of power, control, bureaucracy, progress etc in the runaway evolution of memes. Market as a pseudo-solution of the "coordination" problem.]

Define your memes?

One of the questions I started with was: Why do people write books? One short answer is: They don't, any more than marriages make babies. A book (or a text, a reading, or a comma) is the expression of a complex meme, produced by humans by means of other humans.

I should have liked to make more generous use in this volume of that ancient (and unfortunately extinct) punctuational meme the *cryphia*, a mark inserted at points in the text where "a hard and obscure question cannot be opened up or solved". {Footnote 129}

Maynard Smith has this to say about evolutionary models of culture:

"The explanatory powers of evolutionary theory rest largely on three assumptions: that mutation is non-adaptive, that acquired characters are not inherited, and that inheritance is Mendelian - that is, it is atomic, and we inherit the atoms, or genes, equally from our two parents, and from

no one else. In the cultural analogy, none of these things is true. This must severely limit the ability of a theory of cultural inheritance to say what can happen and, more importantly, what cannot happen" (1988, 119)

My account of memes has provided no proper definition, nor is it exactly placed within falsifiable propositions. I have tried to explain the idea of memes through numerous examples and analogies: genes, images, games, organs, organisms, organizations, letters, words, texts, performances, melodies, jokes, morals, nations, artefacts, machines, money ... and the list could be far extended. Doesn't the hope of a rigorous definition dissolve in the confusion?

Perhaps it does. But does it matter? Think back to Dawkins' meme meme. If it were a phrase we should describe it as self-referent, and philosophers have long puzzled over the logic of self-referring expressions. But it isn't just words, it's a meme. And, like memes in general, the meme meme hasn't got to be where it is, and as it is, by having a rigorously definable meaning (indeed, it's very hard to say, even approximately, what many types of meme *do* mean). Memes get to be as they are by succeeding relative to other memes. In the process they try out numerous competing - and contradictory - variants. As with advertisements, the memes that succeed aren't necessarily rational, dignified or virtuous. At different phases they domesticate our tastes for different tasks. One week science is all the rage. Next week it will be love or war. To every meme there is a season. Among bees the dancing is all about the best way to flowers with nectar; they have no time for logic, justice or science. {Footnote 130}

Perhaps, then, we should be asking different sorts of questions about the meme meme? Not (by analogy with words) "How may we define it, what does it mean?"; but rather in evolutionary or historical terms "Is it succeeding? Which combination of its variants will do best?" To think in evolutionary terms means not measuring phenomena against definitions, concepts against prior purposes or meanings, but concentrating on the becoming of functions, recognising that the difference between logic and advertisement is only relative. Memes share the farmyard with us, and it is up to us which of them we let push us around. {Footnote 131}

Meme diversity and biodiversity

This also applies to genes. Is culture the enemy of nature? As the human population and its memes proliferate they exert a downward pressure on the number of species, without - until very recently - compensating by generating new species. This occurs because successful memes do best and thus find it convenient - that is, relatively most efficient - to domesticate or cultivate human beings, together with a limited number of auxiliary species. Successful memes are those able to invade or expand and occupy the human habitat - the raw material of which is one large-brained primate species.

Meme types' "niches" are intricately differentiated, but the soil in which their nutrition chains are all rooted is the amorphous, all-purpose, new-born human creature outlined (and to that extent caricatured) in the Standard Social Science Model. God may have (in JBS Haldane's phrase) an inordinate fondness for beetles, but memes (of which gods are just one sort) all have an inordinate dependence on humans, and some prosper by indirect parasitism - persuading the human hosts *they* parasitise to invade and lay waste other species and their habitats.

It seems to me that the question "Is culture nature's enemy?" cannot be answered theoretically or generally. It depends upon selective pressures among memes, among meta-memes (such as values) and among other types of meme-complexes (such as cultures and lifestyles). One of the ways that some memes may maintain biological diversity is by a sort of weak domestication of species whose population is threatened: wildlife management of various forms. Species are conserved, as breeds are domesticated, by making them into appealing and therefore successful memes. {Footnote 132}

This is an instance of a more general problem. Because memes function largely by motivating humans there are strong pressures tending to make us interpret the world in terms of our own wishes and needs and to anthropomorphize many types of meme. Just as it needed lengthy genetic and memetic evolution before we could see our world as atoms, or cells, or history, we are only beginning to bring our memetic co-inhabitants of the planet into focus.

As we do so ancient questions arise in new forms. How shall we choose among the memes (and among the other biological species) with whom we share our world? Who will they choose? Is the disappearance of the giant panda a more serious matter than the extinction of a non-literate pantheon, or of slave-powered triremes? What influences should we try to bring upon meme-selection? Should we try to cultivate "friendly" memes, and if so how? All cultures consist of more or less cohesive complexes of memes. What is relatively newer is deliberate efforts from within cultures to reshape themselves, as in socialist or utopian movements, or more modestly in the design and subsidy of recyclable artefacts. Some of the most difficult problems will arise from memetic developments in our technologies for breeding humans. Is it wise, for example, to persist with our approximately 50:50 distribution between female and male, when the sexes differ so markedly in their creativity and belligerence? There will be differences over such questions, and selection among the answers.

Progress and progression

I end with one more speculation. Nowadays the prevalent rates of human memetic evolution have "accelerated" ahead of genetic evolution for large organisms. History may roughly be defined as that phase in the development of the biosphere in which memetic evolution has overtaken genetic evolution. {Footnote 133} Moreover, the velocity of memetic evolution (which we can measure against the more constant-speed "clock" of genetic change) continues to accelerate: where cultures once remained almost unchanged over hundreds of years, they now alter spectacularly between parent and child.

What gave rise to, and sustains, this memetic acceleration? My speculation is that here, too, the cultural proto-sciences may have things to learn from the life sciences. Biologists have paid much, and ingenious, attention to defining, measuring and understanding rates of evolution. I have already tried to appropriate something of their understanding of speciation and sex to appreciate analogous forms of "clustering" among human memes (such as the skill division of labour, or the academic division of knowledge) [cross-ref to passage above].

Another thing that seems to have changed is this: where memetic innovation was once individualized, idiosyncratic and accidental, (some) types of meme have "discovered" the

advantages of routinising innovation. Whereas for a long time most meme lineages were dependent on individuals' effortful but apparently accidental insights - Archimedes' Eureka! or Newton's apple - some more modern memes have developed specialised organs for innovation: R&D departments, creative teaming, sabbaticals, psycho-substance use, postmodern theology, etc. And - partly because the distinction between organisms and adaptations is harder to draw among memes - such organs easily take on momenta of their own. Just as human sexuality, decoupled by contraception from reproduction and morality, proliferates recreational variants, so meme innovation has a tendency to develop as organised addictions among humans. Fortunately for us, in urban society at least, many of them are short lived, and the succession of fashions liberates humans from the absolutism of particular memes. But the "open society" that thus evolves is at least as much a society of memes as it is of humans.

The memetic "take off" can also be seen as exaptations of morality. The initial selective advantages of human morality for memes were mainly stabilizing and conservative: the Ten Commandments, patriotism, diligence, honesty, and so on. But moral memes have increasingly been incorporated in meme exaptations whose advantages lie in their links with innovation - imagination, science, tax avoidance, etc. The clades which vary most eclectically and ingeniously generate many of the memetic winners.

Fashions (which may very loosely be thought of as analogous to cell division and multiplication in the life cycles of multicellular organisms) remind us how very approximately notions - such as those of replicators and interactors - must be transposed from biology to memology. In neither field is it possible to draw one clear division - like means and ends, they interchange. Post-Darwinian biologists have met with large difficulties in their central concepts - yet great progress has been made despite the abstract confusion. Much modern biology developed with assumptions about the relevant "units" of natural selection (the organism, or the group) that may seem unreflective. And defining and distinguishing the lineages on which biological selection acts is still a very live issue. {Footnote 134}

Among memes there is no unit of selection which even appears so clear cut as does the individual organism in biology. That is why, to begin with, I blithely skated over distinctions between more and less complex complexes of memes. Fashions are a very rough analogue of organisms - or at least a relevant and informative level of selection. So, as I suggested above, are (human individuals') personalities. And so, too, are the stuff-in-trade of social scientists: institutions and cultural practices. Durkheim's "autonomy of the social" is relative but very real - Institutions renew themselves through the reassembly of finite personalities - and personalities become material for inclusion in institutions by their formation in (often other) institutions. If we remember this we may be less prone to amplify the dialogue-of-the-deaf between social and natural science, as with the "Standard Social Science Model" and its critics, discussed above.

Most of my suggestions have been directed towards the social sciences. But - as the natural sciences, heavily addicted to the separation of fact and value, are becoming more aware - specialisation and differentiation also involves getting memes crossed - and high levels of juvenile mortality among hybrids.

WHAT'S A MEME: REFLECTIONS FROM THE PERSPECTIVE OF THE HISTORY AND PHILOSOPHY OF EVOLUTIONARY BIOLOGY

By

John S. Wilkins

3 Peel Grove, Mt. Martha 3934, Australia.

Abstract

This paper is intended as a focal article to raise philosophical issues about the nature of memes and memetic theory. To bring consistency to memetic analysis, researchers need to understand and agree upon the theoretical role of memes and the generalized model of evolution in which it occurs as a theoretical term. To help this, I have traced the source of Dawkins' conception of memes from GC Williams' *evolutionary gene* and through to the Hull-Dawkins Distinction between *replicators* and *interactors* and Hull's notion of *lineages* and the idea of an individual in biology. The complexity of biological modes of evolution suggests that conceptualizing memes as disease pathogens is not an alternative to evolutionary models of memetic development. I argue for a close and strict analogy between biology and memetics. I introduce the idea of a *memetic individual* or *profile* to clarify the ontology of memes and their ecologies. Some promising methods from biology and other disciplines such as Hamming Distance and Wagner ground plan divergence methods are suggested. A glossary of mainly biological technical terms used and introduced neologisms is included.

Keywords: Meme, evolution, gene, replicator, interactor, individual, natural selection, term, mnemone, pheme, deme, ecology, epidemiology, mind virus, Lamarckism, Dawkins, Hull, Campbell, Williams

JULIET: *'Tis but thy name that is my enemy;
Thou art thyself, though not a Montague.
What's Montague? it is nor hand, nor foot,
Nor arm, nor face, nor any other part
Belonging to a man. O, be some other name!
What's in a name? that which we call a rose
By any other name would smell as sweet;
So Romeo would, were he not Romeo call'd,
Retain that dear perfection which he owes
Without that title. Romeo, doff thy name,
And for that name which is no part of thee
Take all myself.*

(William Shakespeare, *Romeo and Juliet*, Act 2, Scene 2)

1 Introduction

The fundamental theoretical concept of memetics is the meme¹ - the unit of cultural evolution and selection. The term is unclear in its meaning and what it denotes, and the application of evolution to culture is often based on a partial or even mistaken notion of the general structure of evolutionary explanation. In this paper I give some historical background to the origin and function of the term "meme" from the debates in evolutionary theory out of which it sprang. I argue that there is a close analogy between the entities and processes of biology and culture, although the parameters that describe each domain often differ in their rate and frequency, and perhaps in the dynamics of the evolutionary process they undergo. It is as crucial to understand what the units of evolution in culture are as it is in biology to be able to apply an evolutionary explanation, and for this reason we must be quite clear about what a cultural individual is. We can make better sense of these issues if we look first at the analogous problems of what a biological individual is, especially in the context of what the units of selection are.

Problems that bedevil memetics include classifying cultural entities and reconstructing historical developments, and these also have their analogues in biology. Resolving them depends on determining the level at which selection occurs, for it is selection that defines what is functionally important in evolution, not the contrary. The conceptual tool of most help to us here is the distinction between replicators and interactors. There are three common approaches in memetic writings - most commonly writers picture meme evolution as the spread of disease pathogens, others restrict selectionist accounts to some part of culture that is amenable to this form of explanation such as science, and I argue for a third option. We must more broadly understand the variety of biological evolutionary phenomena, so that we can see the similar patterns in cultural change. In order to assist in this, I introduce the notion of a memetic individual, and discuss the relationship this entity has with the biological organism in which it resides. In the conclusion and prospectus, I suggest some analytical techniques of biology, particularly methods of taxonomy and genetics, which these distinctions permit for memetic research.

I hope both that biologically literate readers will understand my simplifications of biology and that those not familiar with biological terminology its necessity. I append a glossary of various technical terms introduced in this paper and those that are likely to be unfamiliar to non-biologists.

2 The background to the problem

The increase of the conceptual clarity of a theory through careful clarifications and specifications is, as William Whewell observed more than a century ago, one of the most important ways in which science progresses. He called this process "the explication of conceptions" and showed how a number of theories, in the course of their temporal careers, had become increasingly precise - largely as a result of the critics of such theories emphasizing their conceptual unclarity. Many important scientific revolutions ... have depended largely on the recognition, and subsequent reduction, of the terminological ambiguity of theories. (Laudan 1977:50)

Certain terms and notions in both the sciences and humanities are fated to be misunderstood, either because they are first vaguely formulated, or because they are so evocative they generate such immense enthusiasm and are applied to almost everything, coming to mean almost nothing. A classic example is the term of Thomas Kuhn's (1962): *paradigm*. Originally intended by Kuhn to apply to what changed radically in a scientific revolution, it came to be applied to perceptual and conceptual changes in cases of individual, social, literary, political, economic and even consumer choice. When a term of philosophy of science is used to advertise a new car design, you know it has lost any definite meaning. Eventually its author abandoned it under criticism in favour of notions and terms that were more specific, but "paradigm" is now ensconced in popular parlance, surviving both author and intended theoretical usage. The difficulty now with the term for a specialist in the philosophy and history of science is that calling a theoretical change a "paradigm shift" has become little more than a metaphor. It describes only an impression and implies only a subjective assessment.

The basic and central notion of memetics is, of course, denoted by the term meme, Richard Dawkins' (1977) term for what is transmitted in culture that is analogous to the biological gene. "Meme" is in danger of suffering the same fate as "paradigm". It is used to denote, variously, neural structures, cultural artefacts, practices, economic systems, religions, concepts, phenotypic traits, self-awareness, and epigenetic predispositions. Memes are thought by some to control behaviour, by others to be acquired through a choice or act of will. The term gets applied to all levels of social and cultural structure, from minimal semantic entities like phonemes, through more molecular entities like phrases and snatches of music, to entire traditions and world views. In this blooming buzzing confusion, the usefulness of memes as a category is being lost or degraded.

It wouldn't be the first time this sort of confusion has wrecked an emerging discipline - gene, the very term on which "meme" is modelled, has a history of shifting definition and debates in which antagonists argued past each other for more than sixty years. It took the modern evolutionary synthesis and the discovery of the structure of DNA to resolve it fully, and still, "gene" covers a range of theoretical phenomena requiring the more exact terminology of *codons*, *cistrons*, *introns*, *exons*, *operons*, *regulators* and *base pairs*. Even today, biologists use this term differently and inconsistently - what molecular biologists usually mean by it differs greatly from its meaning in population genetics.

A theoretical term is usually generated to denote a causal nexus in the model the theory describes². On at least one recent account (Suppe 1989, van Fraassen 1980) a scientific theory is an attempt to either isolate or idealize a system - usually a physical system - in such a way that its dynamics can be reduced to a manageable number of variables (each of which is usually represented by a theoretical term) related by a mathematical description, so that the model generates a restricted number of likely outcome states. It is often neutral with respect to many of the attributes of the entities and processes it covers: Newton's theory of falling bodies does not mention their colour, for example; the equations of flow dynamics cover water, hydrocarbon liquids, and gases; and information theory covers transmission of bits by electromagnetic radiation no matter whether the medium is electrical, photic or magnetic.

One such generalized scientific theory is the theory of adaptation and evolution by natural selection. Natural selection is a process that occurs over a range of physical substrate entities: viruses, single celled clonal organisms, multicellular plants, animals and fungi, and so forth. Certain variables need to be adjusted to deal with these very different phenomena - life cycle rates, ecological behaviour, reproduction modes and so forth - but the virtue of the theory as a model is that it is highly generalizable and widely applicable. Recently, for example, natural selection models have been applied through the use of computers to a range of real world problems, and have been developed into a class of formal algorithms called Genetic Algorithms (cf. Holland 1995). Problems to which Genetic Algorithms have been applied include political and social problems, through to hard engineering of complex systems like engines and flow dynamics.

To understand the meaning of *meme*, we need to understand the history of some debates in evolutionary biology, and the ways in which evolution and culture have been thought to be related. Even before Darwin published the *Origin* in 1859, evolutionary reconceptualisations of human society and culture were common. The Lamarckian evolutionary tradition through Geoffroy, Grant and Chambers had drawn radical social conclusions based on their view of evolution as progressivist, universal and hierarchical (Desmond 1989). Not long before the *Origin*, Herbert Spencer developed his form of Hobbesian rugged individualism based on a Malthusian struggle for existence, ideas that found a parallel in Darwin's natural history work. But of interest to a memeticist is the application of natural selection models to ideas, by writers like Alexander Bain, Charles S Peirce, William James, Ernst Mach, and John Dewey, very soon after Darwinism was first promulgated through European intellectual society. In many ways, Dewey is one of the first true memeticists, declaring that we didn't so much solve problems as recover from them, appropriating both the Darwinian evolutionary metaphor and the epidemiological metaphor so popular today (Dewey 1909). Over the years, various others have used natural selection as a metaphor, or as an analogy (the distinction is significant³), of conceptual and social change, including Medawar, Popper, Toulmin, and even some leading Darwinians (cf. Cziko 1995 for a review).

Eugenics was a constant source of confusion and debate in the early synthesis, with Fisher and the "Oxford School" along with leading geneticists like Muller proposing that the primary role of natural selection was to trim away deleterious alleles and that the best way to organize society was to permit that process to act without impediment. Dobzhansky and others, largely in North America, argued instead that the role of natural selection was to maintain a pool of variety in populations, and that equality of opportunity would permit whatever alleles had relative advantage to be expressed (Beatty 1987). This was more significant than a clash of political or moral doctrines. Eugenicists (Darwinian eugenics was usually positive - encourage the fitter - than negative - cull the less fit - as in Spencerian social "Darwinism") held that society, or at any rate "civilized" society, acted to lessen the effects of natural selection, while those who like Dobzhansky opposed eugenics tended to see society as either neutral or ancillary to natural selection in biology. The very role of natural selection itself was the subject of intense debate, culminating during the final years of the synthesis and the early 50s. It centred on an extended debate between Fisherians, who saw it as a universal and often all-sufficient mechanism of evolutionary change, and those who like Dobzhansky followed Sewall Wright in thinking that in small populations (demes) random drift and sampling error played a greater or lesser role in the

evolution of traits. Even today this is still an issue. Dobzhansky, who through his early education in the tradition of Russian Darwinism which emphasized co-operation and began with Kropotkin, was well placed to argue for Sewall Wright's notions and by the end of the 1950s, some admixture of drift and selection was accepted by nearly every evolutionary biologist.

The point of this potted history is to show the context in which the meme-analogue "gene" arose and was debated, and to set the scene for the conditions in which memes were developed as theoretical entities; this will go to the question of the nature of memes and their theoretical role in explanation. Throughout the period of the development of Darwinism, it was agreed that there had to be hereditary factors of some kind because natural selection can only act if the traits of organisms that are selected are transmitted to future generations in a process of differential reproductive success based on what we now call differential ecological success. But it took a long time for this to be clarified. Evolutionists often spoke of new traits being "for the good of the species" even though Fisherian genetics modelled fitness as an *individual* property of heritable traits in a population. Indeed, Fisherian genetics treated genes in such an unlinked atomistic way that later writers like Mayr spoke derisively of "bean-bag" genetics, which treated genes as if any single one of them could be separated out from the others and inspected.

Although Mendelian genetics had already realized that genes were often linked in their effects, and that many genes affected each trait (epistasis) and some genes could affect many traits (pleiotropy), it was unclear what natural selection acted *on* - individual genes or the traits they affected. In his 1937, Dobzhansky adopted Darwin's term "co-adaptation" to denote parcels of genes that were selected as a unit because they had evolved together to work well as a team, but there was a real epistemological difficulty in determining what genes selection actually selected.

In 1962, the modern "units of selection" debate was inadvertently kicked off by a naturalist, Wynne-Edwards, who explained the regulation by some gulls of clutch size (the number of eggs laid) during lean times as an adaptation that could only be for the benefit of the group, because individual fitness had to be lower if fewer progeny were produced. Wynne-Edwards used the notion of "group selection" which Darwin had used in 1872 to explain the existence of human moral behaviours: moral groups did better than immoral groups, and so their genes would be better represented later on than those of the others (to reinterpret Darwin's formulation in modern terms). According to Wynne-Edwards, populations that regulated clutch size survived ecological catastrophes better than those that didn't. It's an intuitively seductive idea, but this sort of reasoning was thought to be woolly headed and wrong by those evolutionary theorists raised in the more reductive panselectionist tradition. David Lack argued against the biological specifics of Wynne-Edwards' thesis, but a pivotal outcome of this book was that it spurred George Williams to publish, in 1966, *Adaptation and Natural Selection*.

Williams took an operationally reductive approach; that is, he refused to use selectionist explanations at any level higher in the biological hierarchy than was necessary. It is onerous, he thought, to explain group level phenomena in *sui generis* terms when explanation in terms of the *components* of the group and their properties will suffice. For selection of a group to occur (and contrary to popular reportage, Williams did not rule out the in-principle possibility of group selection, even identifying a case study), two criteria would need to be satisfied. One, the properties that were favourably selected would need to be the properties of the *group*, not the

individuals that comprised it. Williams illustrated the difference by distinguishing between a group of fleet deer (which as a group may move slowly, though all its parts are fast moving) and a fleet group of deer (which may move quickly, as groups go, although its parts are slower than parts of slower groups). Fleet deer are individuals with properties of fleetness. Fleet groups of deer are *groups* with properties of fleetness. The second criterion that must be satisfied is that group properties had to be heritable: copies must be made if selection is to operate. Therein lay the rub for Williams: groups typically do not reproduce. But Williams went even further: neither are individual organisms usually copied. You are not a clone of your same sex parent. You may have your father's eyes, your mother's hair colour and wave, and be intermediate between them in your genetic predisposition to height. Mendelian factors are the basic unit of evolution, according to Williams, and not all of them, either. "I use the term 'gene' to mean that which separates and recombines with appreciable frequency", he said (1966: 20) and he further defined an evolutionary gene (that is, one that is selectively important) as

"...any inherited information for which there is a favorable or unfavorable selection bias equal to several or many times its rate of endogenous change" (1966: 25).

In set theoretic terms: Mendelian factors (M) are a proper subset of heritable separating and recombining units of information (G), and include as a subset selectively biased - that is, evolutionary (E) - factors.

Ten years later, Richard Dawkins (1977) introduced the "selfish gene" metaphor based on Williams' "evolutionary gene". But the way he did so obscured the point Williams was making (not deliberately, for Dawkins had other fish to fry) - not all genes are evolutionary genes. Given that only genes can be evolutionarily relevant, what portion of those genes actually *are*?

Williams is a bit of a panselctionist⁴ and he tends here to brush past questions of random drift and founder effects. His answer to the question is that a gene is evolutionary just insofar as it is subject to selection that exceeds mutation. This is a definition, not a discovery. If it's favourably or unfavourably selected and heritable, it's an evolutionary gene. We are now on the threshold of memes. Williams himself realized this, noting that gene was a cybernetic abstraction, and later describing the notion of a "codical domain" of evolution, wherein the transmitted structure, no matter what its *physical* substrate, is a codex (Williams 1992). In other words, it's a message that is transmitted, and which is subjected to the same theoretical models as any other kind of message transmission, i.e., Shannon-Weaver information constraints. This means that genetic replication is one instance of a class of phenomena in Message World - and memes, like genes, are another.

Dawkins' original introduction of the term "meme" in *The Selfish Gene* mentioned in passing snatches of tunes, crazes and fads, but the paradigmatic example he gave, no doubt due to his personal experience of it, was a scientific notion passed from scientist to scientist. I shall return to this point later, but some properties of scientific notions are of immediate interest. Typically, scientific ideas are either evocative metaphors, like de Candolle's "struggle for existence", that inspired Darwin, or more or less formal models. It is the latter that concerns us here, for when metaphors reach the end of their evocation, they must be turned into formal models anyway in order to be tested against quantifiable phenomena. A formal model like Boltzmann's

thermodynamic entropy is a far cry from Heraclitus' notion of flux, and it does a great deal more conceptual work. The significance of Dawkins' example is that one can, to a relative degree of exactness, determine whether and how far apart or whole of a model has spread to another scientist or textbook, or whatever one takes to be the cultural equivalent of the phenotype - for reasons I hope become clear, I shall refer to this as the phenotype, and the total distribution of co-adapted memetically constituted traits within a lineage the phemorph of that lineage. The neologisms are strained, barbarous and ugly, but I hope they will add some clarity to what is being discussed. In short, scientific examples can be quantified both in terms of their frequency in a lineage of scientists, and their relative rates of increase or decrease. This susceptibility to analysis is essential for modelling change in terms of natural selection, and evolution in general.

3 The Hull-Dawkins Distinction and the evolutionary gene

Do I contradict myself?

Very well, I contradict myself,

(I am large, I contain multitudes.)

Walt Whitman, *Song of the Open Road*

To apply evolutionary models outside biology, you need to know what evolution as such is, no matter what the domain it is occurring in. There have been many attempts within biology to generalize evolutionary modelling, for it is a point worth remembering that even biological evolution is not all of a kind. Evolution occurs over single and multicellular organisms, over animals and plants and fungi, and over various kinds of bacteria and viruses. It applies to sexual, clonal and parthenogenic reproduction, to heredity using DNA, RNA and even cytological structure. Generalist species (*eurytopes*) and specialist species (*stenotopes*) both evolve in widespread and continuous ecologies, and in localized and isolated ecologies, and so on. Evolution is not simple in biology, and so biologists have worked to make it as general a model as possible to cover all cases. There is clearly some common thread in all these phenomena, and most find some or all of the explanation in natural selection⁵. As Weismann's and Wallace's heirs perceive natural selection, it is the differential success of the genotype due to the ecological success of the phenotype it creates. The causal arrow is essentially one way: genes cause phenes but not the reverse. As Cziko (1995), following Donald Campbell, puts it, genes are selected but not instructed. Despite all the progress since Weismann on the nature of biological heredity, his Central Dogma has stood almost without modification⁶. It is therefore important to determine whether there is an analogue in culture for these central distinctions of genotype and phenotype and whether memes are ever instructed, or only ever selected, as genes are. And if memes are instructed, does this "Lamarckism"⁷ of culture obviate the need for a memetic analysis? Although it's worth remembering that Darwin was a Lamarckian on heredity, that is, he accepted that the units of heredity ("pangenes") are instructed, this does not really help us answer the question, for we already have non-evolutionary Lamarckian models of culture and the justification for taking an evolutionary perspective rests on the efficacy of Darwinian, perhaps Weismannian, models. We need to understand the ontology of a Darwinian process to come to any resolution.

Dawkins (1982) distinguished between genes as replicators - things that are duplicated with a high degree of fidelity - and bodies of organisms as the *vehicles* of genes. Vehicles reproduce,

but only genes replicate. Some writers, including David Hull (1980, 1987, 1988a, 1988b, 1988c) took exception to Dawkins' characterization of bodies as mere vehicles of genes - they were, in his opinion, much more than passive and controlled robots⁸. Hull had earlier (1974) attacked explanatory reductionism in genetics, arguing that reducing evolutionarily significant traits to genes was unsatisfactory both in terms of a failure of isomorphic relations (mapping) and also of underdetermination - things happen at metagenic levels that are not, and never could be, the results of the sum of the properties of the genes⁹. He therefore rejected Dawkins' passive notion of bodies and the phenotype, and substituted instead the more ecologically and economically active notion of an interactor. Hull's general view of evolution is of a cycle of replicators coding for interactive traits, which through their interactive success acquire (or fail to acquire) the resources needed for further replication. On Hull's account, ecology makes a strong comeback, and the reproduction of organisms is a necessarily *interactive*, rather than a *replicative*, process. This cycle generates lineages of descent, which exhibit themselves in biology as species in the short term and as phylogenies and other taxonomic classes in the longer term¹⁰.

Hull and Ghiselin, as part of their *individuality thesis* that species are historical individuals, that happen to be made up of many organisms, have also addressed the general problem of what constitutes an individual in biology and evolution in general (Hull 1987, 1988c, 1992, Ghiselin 1997). This also raises its head in memetics, and has not so far been addressed. Their view is that a biological individual, so far from being intuitively obvious (as it seems to be if we only consider obligately sexual vertebrates) is in fact a very fluid category, and their solution is that an individual is *defined* by its functional role in evolution, that is, insofar as it is a unit of selection (this applies to gene sequences as well as to organisms). So, the resultant evolutionary ontology is that replicators (replicanda in Ghiselin's terminology - structures that are replicated, Ghiselin 1987) generate interactors, which are the evolutionary individuals that are subjected to selection and whose economic success or failure biases the regeneration of the replicanda. Plotkin (1994) characterized generalized selective processes as *generate-test-regenerate* cycles, and this helps to clarify the matter (figure 1). An individual is formed at the level of testing, which feeds back into the generation stage. An inclusive hierarchy of individuals can be formed if generation to regeneration cycles occur at higher levels¹¹. In biological terms, this accounts for why colonies of organisms like eusocial insects behave as individuals with respect to selection, and also why clonal lineages (genets) behave evolutionarily as individuals even if they are spatially distinct (ramets).

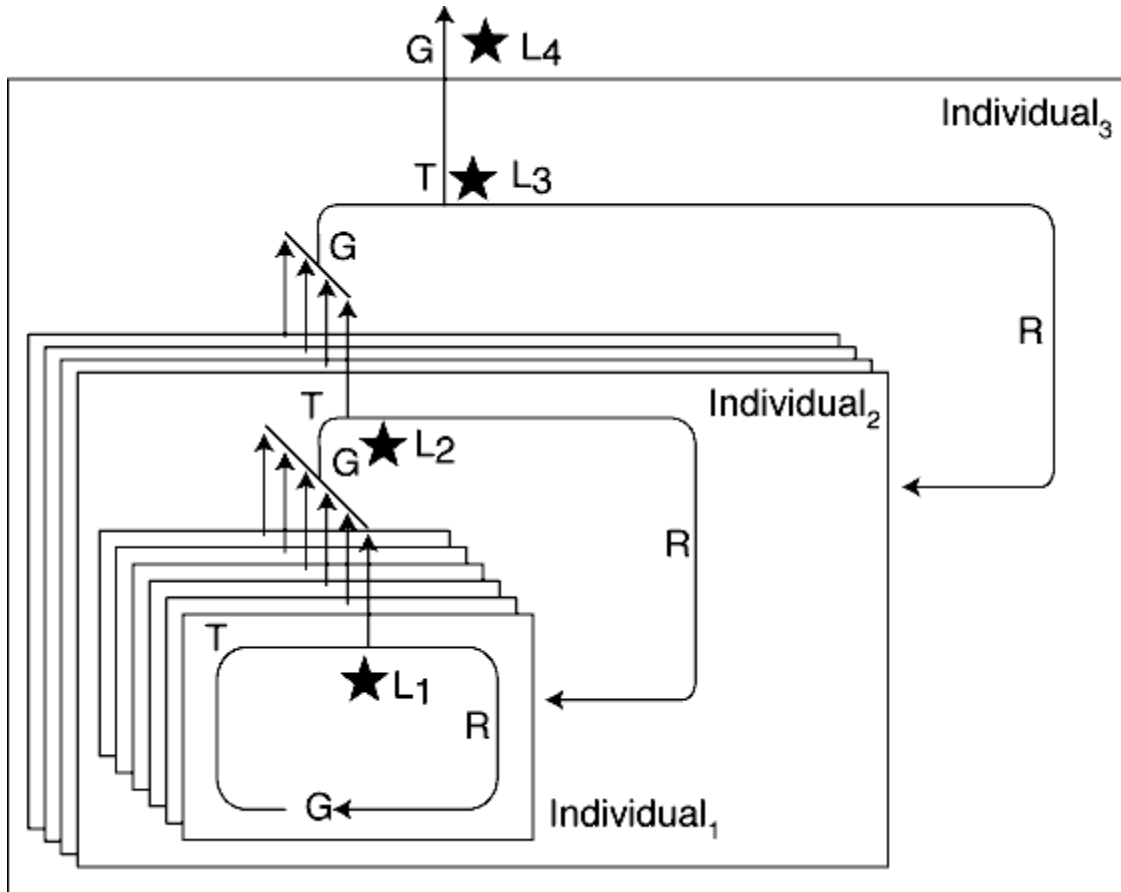

Figure 1. A generalized hierarchy of g-t-r (generate-test-regenerate) cycles in an evolutionary process. Star = Replicators relative to testing/selection bias at that level or higher

The Hull-Dawkins Distinction, as it came to be called, gained almost immediate and bipartisan support across the selectionist debate - both Eldredge (1989) and Williams (1992) accepting that replicators and interactors are the active and general entities in Darwinian evolution (interestingly, both made the now almost obligatory passing comments about these terms also applying to culture.) Dawkins' "memes" (like Campbell's mnemonics, 1974, 1988) are *cultural* replicators, which, if they are to function in cultural evolution analogously to genes, must be transmitted with fidelity, and must cause some interactive traits that in turn will cause a differential replication of the memes. This also helps us with the question whether memes are instructed or selected; that is, whether they arise in response to environmental needs (are "learnt") or are generated randomly with respect to the prevailing social ecology ("random trial and error"). Unexpressed memes (memes not "visible" to the environment through their products) cannot be selected, and so the likelihood of them being prescient or anticipatory is reduced, since we would need to have *already* selected some memes as likely candidates for success in order to predict which ones will work in practice¹². Before a meme can be assessed as "likely to succeed", it must already have passed some tests. We therefore get a regress - any "instruction" of a meme is either a case of transmission followed by selection, or it is a case of transmission of an already selectively tested meme¹³. The Central Dogma remains unshaken for memes, even if some mechanisms of instruction are shown to occur, for even learning is a

selection process (Cziko 1995, chapters 11-12) at some level.

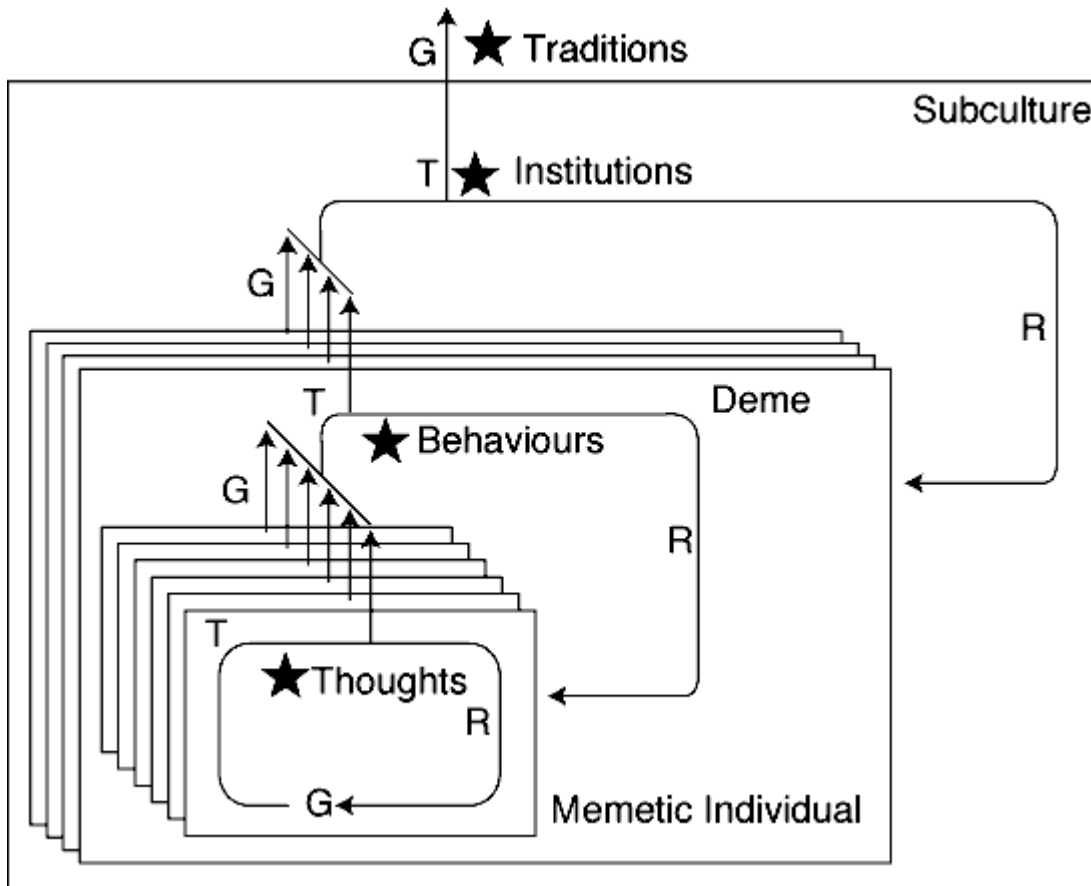

Figure 2. Memes arise as effects of a g-t-r cycle. Star = Meme relative to testing/selection bias at that level or higher

Some may object that memes must be *stored* in neural patterns in order to be considered memes, and that replication through texts, electronic media, and performances, etc., are only secondarily memetic if they affect and are stored in a central nervous system. In figure 2, it can be seen that some selectively biased cultural phenomena can exist as the emergent properties of social systems larger than the individual, and persist without being replicated at time frames far longer than an individual life span. Methodological individualism, as it is called, rejects this in favour of a more parsimonious view, just as genic selectionists like Dawkins reject any form of group selection (Williams' views notwithstanding). But on the Ghiselin-Hull view of individuality in selection, group selection is not only a possibility but an established reality, for viewed appropriately, any organism is a group of related lineages (Buss 1987) and any gene sequence a related group of molecules, and so on. Consider an historical event like the Thirty Years War or an institution like a religion. Political and religious patterns of behaviour in that war need not be stored as neural patterns, and each of the memes of a religion need not reside in at least one brain, for some of these memes are emergent properties of the entire system of acting individuals, and of which they may indeed all be entirely unaware¹⁴. Were Protestants aware of the linkage between capitalism and their theology during the rise of modern capitalist economies, for example? If so, why did it take a sociologist to point it out explicitly? You pays your money and you takes your choice, for the methodological individualist debate has a long history of

controversy in sociological disciplines that continues till this day. However, the view I am advocating here is neither individualist, nor holist, but a view known as "emergentism" (Nagel 1961): the doctrine that the properties of a collective whole arise from the *relationships* between the properties of the components. Simply understanding the componential properties, without understanding the connections between them does not enable us to model the higher level thing they comprise.

So, what are phenotypic cultural traits, the *phemotypes* as I have called them? One answer, and the right one I think, has been given variously by Campbell (1960, 1974, 1987, 1988), Hull (1988c), Toulmin (1972) and Plotkin (1994), to name a few, is that selection acts on behaviour, or, in the language of the logician, on interpretation of the information contained in a meme. Just as a gene must be expressed in order to be selectively biased, a meme must also find expression in some way. While we often use a verbal shorthand when we say that a gene is selected at a certain coefficient, the biologist should never forget that genes are just the starting point of a biochemical process which undergoes selection at a range of hierarchical levels, from the processes of transcription in the cell to the processes of ecological interaction in an ecosystem (figure 3).

Figure 3. Individuals and replicators in a biological hierarchy

Sidebar: interactors and replicators

The terms interactor and replicator, being substantive nouns, give the impression that there are natural kinds of *things* that interact and replicate. Ghiselin (1987, 1997: 147) has argued that a better term for the Hull-Dawkins Distinction would have been between *replicanda* and interactors, that is, between those things that *get* replicated and those things that are economically biased for a range of reasons. When we understand that replication is the passing on of a message, it doesn't really matter what the medium, or substrate, of the message is, and the notion that there has to be some privileged replicator, like nucleotides or neural columns, becomes unnecessary. It is less obvious that interactors are also a functionally-defined class, but if anything interacts (and correlates closely with replicators) then it is an interactor. It could be the organism, but it could be some subsystem of an organism like a class of immunological peptide, or the immune system itself, or a visual system, or it could even be a group of organisms like a hive. There are no privileged interactors *or* replicators, in biology or culture. We would do well to remember Mill's caution:

"The tendency has always been strong to believe that whatever received a name must be an entity or being, having an independent existence of its own. And if no real entity answering to the name could be found, men did not for that reason suppose that none existed, but that it was something peculiarly abstruse and mysterious."

(Cited in Gould 1981: 320)

This modifies Hull's notion of interactor somewhat, for Hull defines them as things, that is, as entities. Plotkin, on the other hand, resists the "entification" of interactors (personal communication). I do not think that Hull's own analysis requires that interactors be a unique class of entity, such as an organism, just as long as it is an *individual* (Hull 1992) with interactive (ecological, or economic) properties. Individuals are entities, but there is no need to restrict individuality to one level of entity, so long as the relevant interactive properties are properties of that entity and not of the system of which it is a component. However, interactors are entities even if they are not a specific *kind* of entity.

Similarly, memes are selected at many levels through their expression in behaviour, including verbal, practical, instrumental and intellectual, and this behaviour need not be the behaviour of individuals; it can be the behaviour of languages, institutions, societies and even traditions.

Consider Campbell's (1974) hierarchy of selectionist knowledge processes¹⁵:

1. Genetic adaptation
2. Nonmnemonic problem solving
3. Vicarious locomotor devices
4. Instinct
5. Habit
6. Visually supported thought
7. Mnemonically supported thought; Observational learning and imitation
8. Socially vicarious exploration
9. Language

- 10. Cultural cumulation
- 11. Science

At level 7, minds construct models to test and select alternatives - and at this level memes are now active and give rise to trial and error without the selective costs to genetically- and biologically based interaction. Memes must result in some outcome that can achieve success or not, on the basis of which they persist over other memes, to be selected at all. The details of Campbell's schema are not important here, but memes *must* arise at some level of information processing complexity, and *must* affect outcomes at levels higher than that. And the converse is also true. Of any cultural process that involves transmission and selection, there *must* be memes that "constitute" phenotypes at that level. Take two examples - a personal attempt to try out a hitherto unlearned linguistic form and a scientific theory. When one is learning a first language, syntax and semantics are underdetermined. A child cannot know, except through trying out combinations and seeing the results, whether a certain "hypothesis" about the use, structure and referents of a word, phrase or syntactical structure is correct. For example, consider how children first learn regular declensions of noun plurals and regular conjugations of verb tenses, and are then corrected by more competent speakers when they use a regular form of an irregular noun or verb - "I swimmmed", "he runned", and so forth. Not only is there an *internal* selection process going on through increasing experience of success, but in a formal sense, these irregular abstract constructs of language are *defined* through the role that they play in the trial and error. Of course, language in itself is not a solitary pursuit, but in *individual* learning, the trial and error selection process is (figure 4, cf. Cziko 1995, chapter 11, Ghiselin 1997, chapter 9).

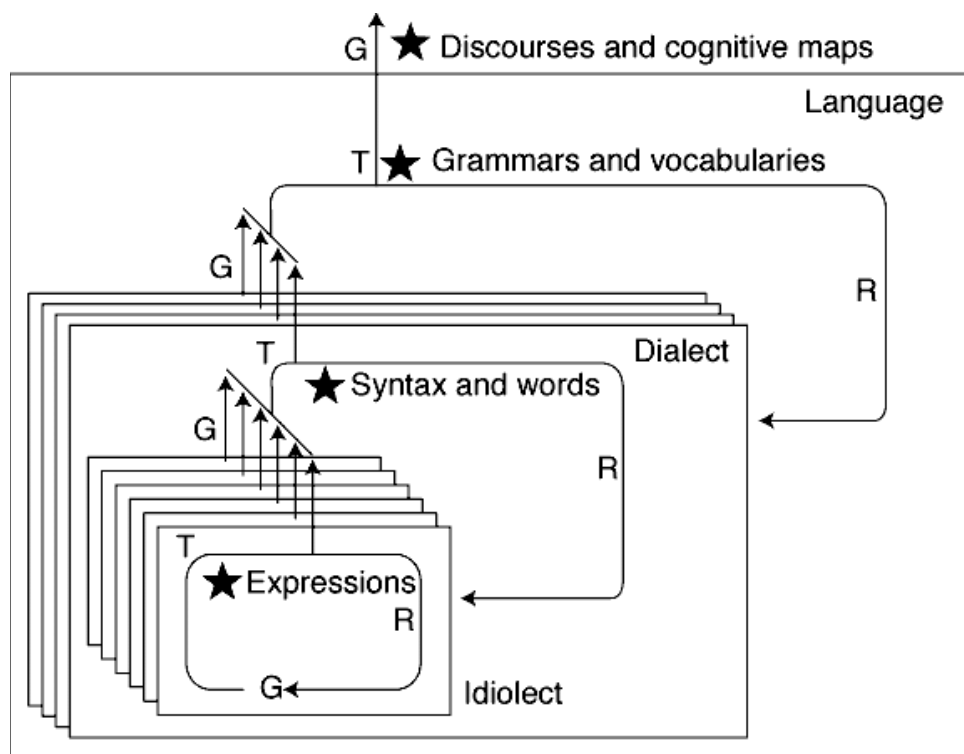

Figure 4. A selective hierarchy of language, following Ghiselin 1997

Back to Dawkins' scientific notions: whatever Mendel, or Darwin, or Newton, internally intended their theories to mean or cover, until the elements of their theories - supporting data, formalizations, explanatory rationales and so forth - were *published* (literally, made public), discussed, tested, and above all in further scientific work, they weren't scientific theories as such. What's more, their theories contained memes of which they were not aware, because they only developed when selection pressures were applied to them. "Action at a distance", or "survival of the fittest", became memes so far as they needed to be defended and supported in the scientific debate when challenged. It is the hallmark and defining characteristic of science that it is presented and tested in the public domain of fellow professionals; and this process modifies theories. Elements of them are quietly or noisily rejected, abandoned or simply never followed up (Laudan 1977). What are the memes of a theory, then? They are those elements of it that are subjected to selection through testing and co-adaptation with the rest of the theory and of the wider field of the scientific culture (Wilkins forthcoming). Theories, like Whitman, contain multitudes (and can therefore contradict themselves), but scientific work consists in large part in exploring the ramifications of a model, in order to eliminate contradictions, either in terms of self consistency and coherence, or in terms of agreement with method and observation.

In the special case of memes in scientific theories, whether or not Dawkins intended it, it becomes clear that in a general evolutionary model a replicator is defined by (1) being transmitted intact, and (2) being subjected to selection. Many things are transmitted in culture that are not selected, and many things are selected that do not get transmitted¹⁶. I conclude that a meme is something (the "smallest" something you can identify) that gets replicated and selected in culture as a unit and therefore offer the following short definition of "meme".

A meme is the least unit of sociocultural information relative to a selection process that has favourable or unfavourable selection bias that exceeds its endogenous tendency to change.

Exceeding endogenous change simply means that it gets transmitted intact more than it gets transmitted mutated (Dawkins' condition of *fidelity*); in other words, it is more information than noise. Compare this with Williams' *evolutionary gene* above.

A single memetic interactive trait, I shall call it the *pheme* by analogy with a *phene* or Mendelian character, is the expression through some behavioural regularity of a meme at the level of selection. "Behavioural" here refers to interactive activity at the level of expression, and so includes mental behaviour, individual behaviour, group behaviour, and so forth (figure 2). However, the behaviour must be both *causally* effective in terms of acquiring resources and must be in some manner empirically *quantifiable*. One question that memeticists should ask of any analysis is "what are the resources"? A scientific theory may gather resources of researchers' time, grants and lab space, publication space in the appropriate journals, and from what I can gather, postgraduate students appear to be a prized resource. Hull's (1988a, 1988c) mechanism is that individual scientists seek to acquire credit, either through innovation, or more probably (since innovation is rare) by inclusion in a successful research project through citation and extension of results. An idea in an individual mind will need to gather attention space, memory resources, and time, in order to out compete other ideas. Without an answer to the question of *what resources?*, and they must be measurable, any memetic account is merely anecdotal.

Sidebar: phenotypes, phemotypes and classification

A phenotype in biology, and especially in taxonomy, is the whole array of organismic characters of an organism, and is distinct from its genotype. In the taxonomic debate between cladism and pheneticism described in Hull's book, the resulting consensus was that there were no privileged features that are phenetic characters (Hull 1988c, Ridley 1992) - anything that can be measured might be used to classify organisms and reconstruct phylogenetic relationships. This argument applies just as well to reconstructions and classifications using genetic sequences as it does to skull shape and the presence or absence of feathers. Some taxonomists think that the best way to identify species is to make use of *non-adaptive* characters on the grounds that these are less likely to be the result of convergent evolution. The popular belief that it is the entire *phenotype* that is the interactor in evolution is, in my view, wrong. Interaction occurs at the level of the trait and the "engineering" fitness of an organism - how well it makes a living overall - is the product of its various interactive traits. The analogy I wish to make is that memes result in behavioural regularities that have interactive properties, that is, which result in social successes and failures.

The **phemotype** is the array of the phemes that are the causal outcome of memes in an individual or group. Phemotypes are the basis for grouping social phenomena, that is, for classifying memetic ensembles into religions, communities, traditions and programs.

Once we have identified a meme in a particular process, though, that is not the end of the explanatory story. Memetics covers what is *common* to the spread of strategies, musical phrases, linguistic practices, ideas and theories, but it does not exhaust the research. Again the parallel with genes is instructive. Having identified that there are factors that are inherited which cause ecologically significant traits, geneticists moved on to identifying the physical processes and their effects, which turned out to be extremely complex, with genes that code for traits ranging from the sorts of proteins that a cell expresses, to genes that regulate other genes, to genes that contribute to a range of gross morphological traits at every level of the organismic structure. Identifying memes will assist in identifying the sorts of cultural phenomena that are functionally transmitted, but we should expect that these will in turn become causes of phenomena in another level of analysis.

4 The lineages and ecologies of culture

Any chain of descent will create a lineage over time and space if ancestral entities terminate at some stage. Given that the obverse of a replicator is an interactor, an economic entity that competes in a formal sense with other interactors for the same resources, we need to identify the resources, the ecologies, of memes. On the face of it, memetic resources include neurological and behavioural time and space, much like a program can tie up the CPU cycles and screen space of a computer, but they must also extend to the more highly derived necessities of social life, including such things as credit, currency, and so forth. Selection processes define not only the replicators (the memes) and the individuals, but also the active and relevant resources of the ecology and economy of social life. The interplay between these facets of memetic evolution leads to successful and persistent lineages, as well as transitory and unsuccessful ones.

The nature of and reasons for lineages in biological evolution is a complex matter. Debates about the "Species Problem" and the relationship between "horizontal", or "non-dimensional" conceptualizations of species - known generally as biological species concepts - and "vertical" or "phyletic" conceptualizations of lineages over evolutionary time - paleontological, evolutionary and phylogenetic species concepts - have been ongoing since at least the modern synthesis, and indeed is sometimes held as the defining debate of the modern synthesis of evolution (Dobzhansky 1937, Mayr 1970, Mayr and Provine 1980). One thing that is generally agreed upon is that ancestor descendent lineages that do *not* regularly recombine (reticulate) at a scale on the order of one generation are not species, but are within-species lineages or something else; for example, what Eigen (1993) calls quasispecies in the case of viruses. In other words, species are those largest collections of biological lineages that do regularly recombine, and which do not themselves recombine with other lineages¹⁷. However, socio-cultural lineages appear to exchange memes on an almost unconstrained basis. Practices, metaphors, and ideas transfer from one cultural lineage, culture or tradition to another with consistent ubiquity. Autochthonous cultures the world over have adopted a range of cultural artefacts from the dominant western culture, for example, and this pattern of dominant cultural invasion recurs through recorded and archaeological history. This reticulate evolutionary pattern is touted as one of the major disanalogies between cultural and biological evolution. If cultural transmission is so fluid and free, it is thought, what use is the transfer of biological to cultural categories and modes of analysis? I shall argue that this objection rests on an incorrect assumption about biology, founded on our metazoan, vertebrate, and mammalian prejudices, and that even if it were true, it would not undermine the memetic enterprise.

Other than accepting the conclusion of this argument from disanalogy and abandoning memes as useful theoretical entities, there are three alternative responses to the difficulty it raises for memetics. The first is to shift ground, and to treat memes epidemiologically; that is, using a metaphor of disease rather than of evolution. Treating memes as pathogens, and trying to analyse the vectors and pathogenic dynamics of memes, is a strategy adopted by Goodenough and Dawkins (1994), Lynch (1996) and others (cf. Dennett 1995:364-368). "Mind virus" is itself a tolerably good meme. The second approach is to restrict memetic analysis to domains like the sciences, where there is a strong selective pressure and a good record of the spread of scientific ideas, and where lineages tend, within certain limits and until recently, to be relatively isolated and *sui generis*. The third is one that I have not seen explicitly presented but which is implicit in the work of Hull (1988a, 1988b, 1988c). This is to see that evolution produces a continuum of results from entirely isolated lineages with the "bridgeless gaps" so beloved of Mayr resulting from obligate sexual recombination through to moderately hybridizing lineages like those of flowering plants and ferns, to regularly recombining lineages - rarely if ever present in zoological biology but frequent in bacterial phylogeny and some forms of culture. Each of these approaches has its merits.

The first response, the *epidemiological model* of memes, takes into account the rapidity of transmission and mutation (relative to the observers) of certain varieties of cultural items like vernacular speech and fashions, and the varieties of strategies they evolve to invade cultural agents and populations. This view does not, however, obviate the need for an evolutionary, selectionist, account of the pathogens (cf. Ewald 1994). It's a matter of perspective. Being hosts to so many pathogens, parasites and symbiots, humans tend to conceptualize disease as sub-

generational and populational events in a relatively short time scale. Nevertheless, epidemics and pandemics like malaria have evolutionary effects on humans, resulting in evolutionarily stable genetic equilibria like the maintenance of sickle cell heterozygosity in regions affected by the transmission of the malarial parasite *Plasmodium falciparum* by some species of the *Anopheles maculipennis* mosquito group¹⁸. But we also often overlook the fact that, from the perspective of the *pathogens*, humans and other animal hosts are just another part of their ecosystem, and our immune systems act as selective environments affecting *their* evolution. It's also a matter of degree: viruses, for example, mutate much more rapidly than the gametes of a metazoan, but this is a difference in rate rather than kind. There is a bias imposed on us by virtue of being multicellular, animals, and living at the time scale we do. Evolution has no such bias. The equations governing (or describing) epidemiology are re-castings of the Fisherian and Wrightian equations covering (or describing) natural selection (Cavalli-Sforza and Feldman 1981), which is what we should expect if we see epidemiological phenomena from the pathogenic perspective and not from the host's¹⁹. What this signifies for memetics is that meme epidemiology needs to clearly distinguish between human minds and memes as entities that generate their own separate lineages. More on this shortly. For now, it is worth observing that meme lineages may not be so obvious as we think, and that cross-lineage borrowing, which occurs within biology as well as culture, may be less frequent than seems the case when we view memetic evolution from the perspective of the host minds.

The second response, the *narrow conception*, is to restrict the application of memetic analysis to those cultural phenomena which are phenomenologically isolated, well recorded, or in which there is a clear selective pressure such as in technological, scientific or economic change. There is some merit to this: but it is a heuristic merit rather than a theoretical limitation. It is a bit like the situation facing early genetics. Genes were, in the heyday of the Mendelian revolution, theoretical entities that some of a positivistic bent considered mere instrumental constructs. Positivists held (and hold) that theoretical constructs have no ontological import. "Genes" were useful in calculation and modelling, but it was illegitimate to infer that any such biological entity existed. In retrospect, this made a metaphysical virtue of a methodological necessity. Once the science, and ancillary sciences and techniques such as x-ray crystallography, had developed further, physical genetic entities were discovered and described, but this was not open to the early Mendelian researchers, and in fact attempts to describe the physical properties of genes by Weismann and others resulted in failure and open speculation. Had this positivistic operationalist approach been taken seriously, the molecular structure of genes might never have been investigated and discovered²⁰. It *might* be a good strategy to begin with the more accessible areas of research like the history of a science, and to develop methods and models that can be extended later as more problematic cases come within theoretical reach. In the same manner, biological concepts like "species" are often developed in relatively clear-cut cases like sexually recombining animals and plants, and then extended into cases of parthenogenic, polyploid, clonal, viral and other "eccentric" lineages. We must, of course, beware of biting off more than we can chew, but also of not closing off any further avenues of research. Memetics, like any science, must evolve gradually.

The third response I'll call the *generalist conception*. This is to more broadly characterize biological evolution. As Hull has said, there is nothing so outlandish that an example of it cannot be found in biology somewhere. For example, take the cases of reproduction modes and

speciation: memetic evolution appears to be more like the evolution of plants, which have an estimated 30-40% rate of reticulation, and fungi and single celled organisms, with monoparental or clonal reproduction, than it is like zoological evolution with which most non biologists are familiar. Nearly half of all flowering plants are the result of joined lineages rather than split lineages, and nearly all fern species. Amoeba undergo a process called conjugation where genes are exchanged every few generations, although the rest of the time they split aparentally.

Amazingly, even viral RNA can be exchanged through crossover of transcriptase in superinfected cells²¹. Evolution is still cleverer than we are. These idiosyncratic forms of individual, phenotype, lineage and evolutionary behaviour are nevertheless covered by the various theories of evolution²². The generalization of evolutionary theory accommodates these "eccentric" cases just as well as it does the paradigmatic case of animal evolution on which it was first founded. Natural selection is an emergent process acting on ecologically interacting replicators, and obligately sexually reproducing individual organisms are just a special case, even though they are the most obvious and easily investigated form of evolution *for us*.

Therefore, it would seem that natural selection can model cultural lineages even if they do not happen to form tightly integrated populations of recombining entities. But we need to investigate *a posteriori* whether any particular kind of cultural lineage is tightly integrated like an animal species or not, and not to assume that there is, in fact, such a disanalogy. Some are, some are not.

Of those that are not, selection may be a major cause of change or it may not. This is an empirical argument, not an axiomatic derivation. In other words, we should challenge the major premise of the disanalogy argument in each case. The issue of "quasi-species" (Eigen 1993) in obligately clonal bacteria and viruses illustrates this. In principle, and intuitively, every time a clone or virus generates a mutant, one gets an entirely new strain. We might expect that strains would indefinitely diverge to fill the entire space of ecological niches available. In fact what happens is that viruses tend to cluster about the "wild-type" phenotypic mean (which may not even exist in a single genome), forming analogues to recombinant species. Natural selection accounts for this as well as it does for sexual, biparental species.

While on the topic of cultural lineages and species, let us consider the matter of speciation mode. There is a raging debate about whether sexual species speciate through allopatry (geographical isolation) or sympatry (geographical and ecological coexistence) or some intermediate state (parapatry) (Mayr 1970, Gibbons and Morell 1996)²³. This resolves to the question whether natural selection, as well as being responsible for allele frequencies *within* a breeding population and for adaptation overall, is also responsible for *creating* lineages. Those who, like Mayr, opt for the allopatric and parapatric modes alone, consider that isolation followed by selectively neutral or decoupled drift is responsible for speciation, and they tend to see selection as an ancillary process to speciation rather than a reason for it. Sympatric speciation is a litmus test of whether one thinks selection is the main or even the only mechanism of evolution. If species can diverge in the same ecological territory, it must be because selection causes multiple modes in the one population, leading eventually to more than one species as the modes chase different adaptive peaks. If correct, this means that selection can cause speciation, and the traits of species that differentiate them are adaptive. If one denies this happens, or that it happens very much, then what differentiates species can be adaptively neutral or even maladaptive. Nobody presently

thinks that selection can be dispensed with even in cases of speciation by hybridization of plants, which occurs in a single generation or even repeatedly (polyploid speciation), but the differences in the degree of the attributed importance of selection points to a deep division in modern evolutionary thought, and this is very important for memetics if memetics is based on selectively significant cultural transmits.

Hull (1988c) has addressed similar issues in scientific evolution. He uses Wright's notion of structured and relatively insulated breeding populations - called demes - to characterize research groups. According to him, scientific research arises first within relatively co-operative demes of scientists - groups within which more variation is tolerated and selection pressures are less severe than in the wider discipline. This permits new theories to be developed and articulated to the stage where they may be able to survive rigorous criticism by rival groups when published. Intriguingly, Hull does not require unanimity of opinion within the deme, but merely a desire to increase one's credit by sharing in the conceptual inclusive fitness of the deme: reputation is everything in science. Hull's view of the social and conceptual development of science is a well developed model of conceptual change, one of the most articulated memetic models yet presented, and it can be extended into other domains. For example, although Hull does not characterize demonic structure itself in this way, it can be thought of as an evolutionarily stable strategy for science to adopt - with a balance between public debate and private support, conceptual transmission in science is able to develop a great deal more novelty and yet retain more strongly tested ("more fit") ideas than was possible in the late medieval guild tradition from which it sprang. Neither a selectively moderate social ecology nor a naked selective environment where new ideas are never given a chance could provide the sort of adaptive growth science has achieved. Obviously, periods of stagnation in a discipline may be due to changes in these parameters (for example, transmission rates) and connecting them in a model based on a generalized evolutionary and ecological process is an important first step to a full memetic analysis of science. *Mutatis mutandis*, the same is true of memetic theory in general. If we are to understand how memes diversify into relatively stable lineages like religious traditions, the structures within which novelties arise and the selective pressures to which they are exposed are crucial²⁴.

Ecological succession is another analogue of value. It is well recognised in biogeography that niche occupiers in an ecosystem can often fend off adaptively superior invaders; the dominance of a given (say) grazer species in a locale may be due to it being there first rather than its overall adaptive excellence. We should expect that ecological succession, which is complex in biology, will be equally or more complex in culture, but there may be fruitful avenues to explore here. To understand and employ these analogues, we also need an analogue for "ecology" and "ecosystem" for a given socio-cultural domain. The ecology of science, for example, is not nearly as simple as the falsifying crucial experiments that Popperian cycles propose. The resources for which a social or conceptual structure competes will usually be fairly broad even if, as in the case of a scientific idea, storage and processing space and time in an active central nervous system is the basic resource.

5 Memetic individuals

With the clarifications and mental tools introduced above, we are now able to ask Hull's question from biology - what is an individual? - in the memetic context. What is a memetic individual? What is subjected to selection in culture? What gets "coded for"?

When Juliet bitterly but eloquently complained how Romeo's social relationships were messing up their love life, she made the interesting observation that being a Montague, and being the person she loved, were two distinct states (apparently she had more of an interest in some of Romeo's biological aspects). The instantiation of the cultural relationship "is a Montague" in a particular biological organism, denoted by the name Romeo, is a case where an individual is something other than the sum of his own memes. The converse argument was given by the idealist philosopher FH Bradley in 1876, in a landmark essay in ethics, "My Station and its Duties". Here Bradley wishes to establish that one's social location and relations determine one's moral responsibilities. To do this, Bradley argues that what we are as social beings, as moral agents, is determined by the community of which we are part. An Englishman is not his biology²⁵. In each case, Juliet and Bradley recognize the distinction, often overlooked by meme enthusiasts, between the biological and the memetic. Memes don't necessarily make you more biologically fit, nor are they necessarily going to make you less fit. Memes aren't fit themselves simply because they make you live healthier lives. Memes are fit only insofar as they are propagated successfully; forget the effects they have on biology. In Toulmin's (1972) underappreciated book, he says of biological and cultural evolutionary processes that they are *decoupled*. This is not to say that the two realms do not meet and affect each other, for clearly they do; it is to say that no matter how you might be able to conceptualize cultural phenomena in biological terms (socio-biology), you can independently conceptualize them in social terms (memetics). To lift a phrase of Williams' (1992) there is a dearth of shared descriptors between the entities of biology and the entities of culture. Sometimes they may, indeed, be the same objects or processes, but you have to describe them differently in each analytic realm.

No end of confusion has been caused by ambiguous specification of the socio-cultural analogues of phenotype and genotype. An early criticism of Hull's model of models (Heyes 1988, Tennant 1988) was that scientific memes failed to *constitute* scientists in the same way that genes constituted organic individuals. By the same token, critics argue that selection against memes fails to result in the death or restricted fertility of scientists, and so natural selection is an inappropriate way to model scientific theory change. Another recurring criticism of evolutionary pictures of culture is that unlike organisms and their genes, cultural agents choose which memes they adopt, and that they modify their memes in the light of experience. Cultural change would be Lamarckian, say critics, if it evolved at all. These two attacks on memetics - the *aphenotypic* disanalogy and the *cultural Lamarckism* criticism -- are closely intertwined, and have to be discussed together.

Using the relatively clear case of science as an example, we can see that any one scientist can adopt differing memetic stances over time. When Einstein was learning physics, he was probably taught the axiomatic observer independent Newtonian theories of the day. He later changed his mind about that. When the physicist Schrödinger got interested in biology, he entered into the canons and data of a new discipline (for him). Here are two exemplary cases of memetic

acquisition - the replacement or supplementation of one set of memes with a whole new set. Yet, neither Einstein nor Schrödinger became different organisms with these memes. Moreover, had either of these scientists undertaken a non-scientific hobby requiring much technical knowledge and experience, such as angling, oil painting or cabinet making, the likelihood is that they would be able to keep them relatively distinct from the professional standards and methods of physics. So, how can a "physicist" be *caused* to come into being by memes, in the same way that a blackbird is *caused* by a blackbird genome?

I tacitly answered this question by inserting the word "professional" above (cf. Wilkins forthcoming). A human organism who is a member of a culture, language group, class and so forth, only achieves professional status or competency upon completing some portion of a "developmental" process of acquiring and exercising the relevant memes. A scientist, to return to our example, must acquire the standards, knowledge base and experience of the particular discipline (physics) and the sub disciplines (for example, high energy physics). There is an *aspect* or *profile* to every scientist that is (a) constituted by memes, and (b) within the distribution curve of traits exhibited by the lineage (the *phemorph*). As a scientist, an organism is distinct from other cultural profiles he or she instantiates, and the profile is a separate class of entity from any biological organism of species *H. sapiens* or any set of traits that the organism exhibits by virtue of being a member of the species. Bradley considers the thought experiment of raising the same biological organism now an Englishman in another society, or on a desert island. Clearly, says Bradley, not in these words, the *properties* of Englishness are derived from the relational and (non-biological) developmental processes of living in English society and having a locus there. In our terms, "being English" is a memetic profile derived from the acquisition of Englishness memes. We therefore have to be careful of the denotation of the terms "scientist", "Englishman", "capitalist" and so on. The scientist-as-organism is a distinctly *biological* entity, distinct from the *cultural* entity scientist-as-Englishman, or scientist-as-capitalist, which depend for their specification on the memetic profile of the scientist proper, the scientist-as-professional. In the context of a professional lineage such as a science, or other intellectual pursuits or social practices such as accounting or rap dancing, the memetic individual is the competent member of the lineage, which is developed by the lineages' professional or cultural properties to create a profile within the human (biological/neurological) individual organism. With appropriate adjustments, the notion of a memetic individual can be generalized from the case study of science into other discernible cultural institutions and traditions. In the limiting case, where the cohesion of a lineage is very loose, memetic individuality may be partial or fragmentary (like being good at using a yoyo), but if memes *constitute* anything at all, they constitute the profile of a memetic individual.

Memes, like genes, can only "code for" a norm of reaction. All cultural as well as biological traits are distributed over a population curve, with the mean and the mode correlating to the memetic selection bias. As Hull observes, no two scientists even with identical theoretical commitments interpret their views exactly the same way, and it is an oft repeated half joke, half complaint, that there are as many views in a research program as there are practitioners, sometimes even more. Neither memes nor genes determine all aspects of the properties of the entities they constitute. What they do determine are the degrees of freedom and they bias and constrain the outcomes of the so-constituted system. In thermodynamic phrasing, they specify the field of states such memetic systems have a propensity to attain. Do they do this through a

process analogous to the Weismannian Central Dogma, with a one way germ lineage, or through something analogous to a Lamarckian pangenesis (Hull 1988c, chapter 12) with the environment instructing the memes? Is the question even relevant? Cultural and biological evolution *are* going to be different in the frequencies of the kinds of processes they undergo. Perhaps culture does exhibit Lamarckian-style inheritance through the sort of environmental instruction that has a never, or rarely, occurs in biological evolution. One outcome of this would be that variation would come more frequently and more intensively than in a purely Weismannian process, which has to await random mutation or use stored variation from earlier mutation in order for selection to have something on which to operate (Fisher 1930). It would, however, still be Darwinian *evolution* even if *inheritance* were Lamarckian. Lamarckian *evolution*, however, is a different sort of process altogether, driven by perceived need to achieve foreseen outcomes; (see⁷). Lamarckian *inheritance* is not inconsistent with a Darwinian model of memetic evolution. Lamarckian *evolution* would totally demolish the foundations of memetic theory, and leave us with more traditional forms of cultural analysis. However, I do not think that the case has been made that memes are even acquired through instruction in the Lamarckian sense, and refer readers to Czikó's (1995) discussion for further consideration.

It is my opinion that cultural inheritance is not particularly creative, and that most "novelty" is in fact the recombination of pre-existing memes in novel ways: there is little that is new under the sun. Neither do I think that the rate of creativity rises in times of stress or great change. I speculate that what changes, and gives the appearance of memetic novelty, are such factors as selective pressure coefficients, "migration" rates, and density dependent recombination rates that vary from the "usual" background rates. Problems can persist for long periods even in the face of urgent need, and unless the appropriate combination of memes occurs, more or less at random²⁶, they do not get solved. This takes us back to the question of the demonic structure of culture - too great an isolation and a more optimal memetic combination is unlikely; too little isolation, and combinations are unlikely to be stable enough to undergo selection, and will be swamped.

The one major disanalogy Hull accepts between biological and cultural evolution, and with which I agree, is in the rate, but not the kind, of reticulate phylogeny; that is, in the merging and crossover of memes between lineages. Again this is not so much a difference of kind as of degree. As noted above, cultural evolution resembles that of bacteria, plants and fungi more than that of animals - Marvell's "vegetable love" that grows "vaster than empires" is perhaps the better analogy, although on an evolutionary time scale, culture is anything but "more slow".

It might help to visualize the analogy I am proposing by giving examples in a table of the analogues between biological and cultural entities and processes, mapped to the Hull-Dawkins and Ghiselin-Hull ontologies (Table 1, cf. Ghiselin 1997 for a review).

Entity (e) or process (p)	Biological	Memetic	Science	Language	Economics
Interactor (e)	Phenotype or trait	Phemotype or PHEME	Experiment or Observation	Linguistic behaviour	Enterprise or transaction
Replicator (e)	Gene	Meme	Theory or Hypothesis	Language element ²⁷	Account, resource
Character (e)	Mendelian Trait (phene)	PHEME	Method, Result	Linguistic practice	Business practice
Lineage (e)	Species, phylum	Tradition, institution	Research program	Regional dialect, language group	Business, industry
Economy (e)	Ecological system	Culture	Disciplinary community ²⁸	Language community	Market sector, fiscal system
Reproduction (p)	Organismic reproduction	Constitution of new profile	Degree, training	Language acquisition	Establishment of new enterprise
Individual (e)	Organism, kin group, colony	Memetic individual	Scientist	Language speaker	Economic agent
Substrate ²⁹ (e)	Organic molecules	Neural networks			
Code (p)	DNA alphabet	Semantic	Semantic and mathematical	Grammar and vocabulary	Currency
Encoding medium (e)	Amino acids, proteins	Neural structures, practices	Neural structures, journals, books, institutions, disciplinary associations	Neural structures, written material, recordings, etc.	Neural structures, computers, books, ledgers, receipts, bank files, etc.

Table 1 Examples of general evolutionary analogues (e=entity, p=process)

It must again be stressed that these are only some of a number of possible sets of analogues, and what functions as an interactor at one level may function as a replicator at another, so that a pheme for one level may be a meme at another, and vice versa.

6 Conclusion and prospectus

6.1 Conclusions: My conclusions are as follows. Memes are those units of transmitted information that are subject to selection biases at a given level of hierarchical organization of culture. Unlike genes³⁰, they are not instantiated in any exclusive kind of physical array or system, although at base they happen to be stored in and expressed from neurological structures³¹. Many memes reside as neural net structures in the central nervous systems of humans, but many also emerge at a higher cultural level. All memes have neural substrates, but not all are encoded in those substrates. Memes are also situated in a variety of larger semantic structures, behavioural regularities, and cultural substrates. They are identified in virtue of their selective roles. Memes must be expressed in a cultural ecology in order to be selected, but it is the *class* of behaviours rather than the behaviours themselves that are memes. Memes do not control behaviour (including mental behaviour) rigidly, but bias and constrain it to a norm of reaction. Memes are the replicators of cultural evolution and the structures that bear the cultural properties they express as are the interactors, in the language of the Hull-Dawkins Distinction. They are, as Hull once entitled a paper (1987), genealogical actors in ecological roles. Packages of memetic interactive properties - phemes - constitute the phemotype of memetic individuals, or memetic profiles, that are not coextensive with the descriptors of the biological individuals in

which they are instantiated, and cultural evolution is neither identical to nor derived from biological evolution. Memetic inheritance may be, but probably isn't, analogous to Lamarckian inheritance, but in any event, memetic evolution is Darwinian. Memes form ancestor descendent chains of populations that ramify and reticulate with frequencies differing from biological phylogeny, but the differences appear to be within the extremes of the parameters of biology. The models developed for biological evolution and ecology need to be understood more broadly than just vertebrate animal evolution and applied as they are suited to culture, in order to determine the general evolutionary properties of both domains.

6.2 Methods: The methodological future of memetics lies in the use of techniques drawn from information theory, modern taxonomy and computer science. By interpreting memes as messages, we can make use of Shannon-Weaver entropy (cf. Brooks and Wiley 1988), cladistics (Wiley, et al 1991), and connectionist mathematics as implemented in the Artificial Life program (Holland 1995), but as each of these requires quantification of the data or input, it is important to be able to commensurably map the memetic elements and to measure the selection biases they undergo. If, as I have argued, a meme exists in virtue of biased transmission rates, then there is no smooth reduction of memetic structures from cultural behaviour to atomic memes, just as there is no smooth reduction from phenotypic traits to single genes. The researcher seeking to explain a singular historical shift of memetic frequencies must iteratively refine the data until it becomes clear what is being transmitted at a level and how it is being expressed. The problem of classification lies at two ends of the scale - identifying cultural traditions as they exist now and over time, and identifying elements of those traditions as they persist and recombine. Although this sounds subjective, it need not be. Behavioural regularities indicate that something objective has been spread, and even if the underlying memes cannot be formulated in some universal logical language, the structure of memes can still be identified in the same way as Mendelian genes and molecular sequences, through the use of consensus maps and by noting when their absence or presence makes a difference.

The analytic tools available to us are legion, having been developed in biology over a century or more. They include Wagner ground plan methods (unrooted character similarity trees based on presence-absence matrices), Hamming Distance measures (the sum of the number of simple differences between two memes)³², cladistic reconstruction using parsimony methods,³³ and pattern recognition methods that use neural networks and other connectionist models. Eventually, these and other methods will no doubt be incorporated into a body of canonical techniques within the memetic enterprise, and I expect they will be generalized as methods applicable in a range of social disciplines. The methods being developed for complex adaptive systems theory at the Santa Fe Institute are also likely to become important for memetics as well as other research dealing with complex adaptive phenomena (Casti 1994). However, if we lack clarity on the core ontology of a selection process in culture, the data to which we could apply these methods will be subjective and the explanations that we derive from them are in danger of being entirely vacuous.

Acknowledgements

I am indebted to Mario Vaneechoutte and Mark Mills for critical comments on an earlier draft of this paper, and the referees for subjecting the submission to strong selective pressures on style

and content. I must also thank the late David Rindos for encouragement. Major stylistic improvements are due to the attention of Vladimir Brusic, though he is not to blame for any remaining infelicities.

Glossary of technical terms used

Allele

An alternative gene at a particular locus.

Allopatry

The state of populations living apart from each other (literally "other homeland"). Hence, *allopatric speciation*.

Central Dogma

Weismann's hypothesis that gametes ("germ cells") are passed on independently to what happens to the organism's body.

Cladistics

Taxonomic classification that reconstructs the order of the appearance of evolutionary novelties from their present distribution. Also known as *cladism*.

Cladogenesis

The origination of a new species by the splitting of a single lineage into two. See *speciation*.

Co-adaptation

The process of local adaptation of genes and their effects to each other, so that they function well as a unit.

Conjugation

In some single celled organisms, the occasional exchange of genes in otherwise asexually reproducing organisms.

Deme

A small population that is relatively isolated from the larger species or tradition and has its own distinct genetic or memetic characteristics.

Emergentism

The metaphysical position that properties arise from the relations of objects that are not properties of the objects themselves.

Epistasis

Linkages in the effects of genes, such that a single gene may affect many traits or a single trait may be affected by many genes.

Evolutionary gene

"[A]ny inherited information for which there is a favorable or unfavorable selection bias equal to several or many times its rate of endogenous change" (Williams 1966: 25)

Evolutionarily stable strategy

A strategy coded for by genes or memes that does better when interacting with copies of itself than alternative strategies do, and which will tend to become the sole or dominant strategy of a population that will not then be susceptible to invasion by other strategies.

Facultative

Of an organism, the possibility to adopt variant lifestyles, one of which is the norm.

Founder effect

The evolution of a new lineage based on the sampling errors of the small starting population, which may be of different proportions to the original populations.

Gamete

The sex cell of each parent, which recombines to produce the zygote, such as sperm and egg, or spore.

Gene

The fundamental physical unit of heredity that transmits information from one cell to another and thus to successive generations.

Mendelian gene: a unit of heredity that causes a single phenotypic character or trait.

Molecular gene: a sequence of nucleotides (DNA, tRNA or rRNA) that functions as a unit during transcription and which is transmitted whole.

Evolutionary gene: see evolutionary gene.

Genet

All the clonal entities that share a genotype.

Genome

The complete complement of the genetic material in a cell or carried by an individual.

Genotype

The genetic constitution of an individual, often referring to genetic basis of some particular characters.

Heterozygosity

Carrying two different alleles from each parent at a locus.

Individual

A relatively well bounded and functionally coherent system comprised of components and their relationships. The formal opposite of a class or universal type.

Interactor

"[A]n entity that interacts as a cohesive whole with its environment in such a way that this interaction causes replication to be differential" (Hull 1988c: 408).

Lineage

"[A]n entity that persists indefinitely through time either in the same or an altered state as a result of replication" (Hull 1988c: 409).

Meme

The least unit of socio-cultural information relative to a selection process that has favourable or unfavourable selection bias that exceeds its endogenous tendency to change.

Memetic profile

The array of memes that constitutes a memetic individual.

Memetic individual

A competent member of a memetic cultural lineage, which is developed by the lineages' professional or cultural properties to create a memetic profile within the human (biological/neurological) individual organism.

Methodological individualism

The philosophical belief that collectives and their properties are just the sum of the individuals and their properties that comprise them, especially in social and historical explanation.

Mnemone

Donald Campbell's term for a conceptual replicator, roughly equivalent to meme.

Norm of reaction

The distribution curve of the phenotypic effects of a gene in a population.

Obligate

Of a parasite, the forced mode of living or the necessary host. In general, the lifestyle that an organism is forced to adopt.

Pangenesis

Darwin's theory of heredity, a use inheritance view, in which parts of the body were supposed to throw off "gemmules" that were carried to the reproductive organs, and which carried information about the body's experience to the next generation. This view was discredited by August Weismann in the 1880s.

Panselectionism

The view that all characters of an organism have an adaptive reason for evolving.

Parapatry

The state of living in adjacent regions with or without some overlap ("bordering homeland"). Hence, *parapatric speciation*.

Parthenogeny

Asexual reproduction through unfertilized eggs of a lineage that evolved from a sexually reproducing ancestral state. Adj. *parthenogenic*.

PHEME

A single memetic interactive trait which is the expression through some behavioural regularity of a meme at the level of selection. It is the least type of selectively biased behaviour relative to a culture.

Phemorph

The normal distribution curve of traits exhibited by a cultural lineage.

Phemotype

The array of the phemes that are the causal outcome of memes in an individual or group.

Phene

A Mendelian character or trait. Adj. *phenetic*.

Pheneticism

Taxonomy based on the groupings of phenes, without respect to evolutionary lineages.

Phenotype

The observable features of an organism, which develop according to its genetic code (genotype). Adj. *phenotypic*.

Pleiotropy

The state in which one gene affects two or more phenotypic traits not otherwise directly related.

Polyploidy

The fusion of three or more complete sets of chromosomes, sometimes from distinct species, usually in plants.

Quasi-species

Manfred Eigen's term for clusters of related clonal organisms that mimic species in the way they remain similar.

Ramet

An entity that is one of a number of genetically identical organisms.

Random drift

Sewall Wright's model of random allele frequency changes in small populations without the operation of natural selection.

Reductionism

Explanatory reductionism: the philosophical doctrine that a complete explanation of a complex whole is given by enumeration of the components of that whole and their properties, especially in scientific explanation.

Genetic reductionism: a form of explanatory reductionism that has developed into a research program, which holds that all phenotypic properties of organisms and their evolution can be understood in terms of genes and their fitness levels.

Replicator

"[A]n entity that passes on its structure largely intact through successive replications" (Hull 1988c: 408).

Reticulation

The recombination of distinct phylogenetic lineages. See *speciation*.

Selection

"[A] process in which the differential extinction and proliferation of interactors cause the differential perpetuation of the relevant replicators" (Hull 1988c: 409).

Spandrel

Gould's and Lewontin's (1979) term for a trait or structure that is a necessary by-product of some other adaptive feature, and which is not therefore explained in terms of selection in favour of it.

Speciation

The process of the evolution of a new species, through splitting from an existing species (cladogenesis). Also used of hybridization of existing species to form a third (reticulation).

Species

The largest collections of (sexually reproducing) biological lineages that do regularly recombine, and which do not themselves recombine with other lineages.

Sympatry

The state of coexisting in the same region ("same homeland"). Hence, *sympatric speciation*.

Use-inheritance

Also called *soft inheritance* (Mayr 1982: 691). A view held by Darwin (*Origin* chapter V) that "use ... strengthens and enlarges certain parts and disuse diminishes them, and that such modifications are inherited". Sometimes called "Lamarckian inheritance", although Lamarck was not the first to propose this view, which is a folk belief of long standing. In Darwin's theory of pangenesis, use-inheritance is responsible for modifying the frequency and novelty of variation, and therefore evolution. Fisher (1930) discusses the problems of use-inheritance for Darwinian evolution, and the arguments against it.

Notes

1. Technical terms are linked to definitions in the glossary and discussed, where relevant, in the body of the paper.
2. That is, it represents something causally significant in the theory, like an electron.
3. An analogy between two domains depends on a common etiology. A metaphor can only suggest limited and vague similarities. For instance, the term "analogy" in phylogeny refers to convergently evolved traits through adaptation to similar conditions of life. If selection of culture is an analogy, it has theoretical weight; if a metaphor, we can abandon or modify it when we find it difficult to apply.
4. And Dawkins is a *lot* of a panslectionist. Panslectionists tend to find selective explanations for every feature of organisms, for instance asking what the adaptive significance of the human chin is, when chins are just the result of two growth fields interacting.
5. By "evolution" I mean the generation of variations and adaptation. I am not committing myself to the claim that natural selection is, or is not, responsible for new species through cladogenesis.
6. Weismann was the first researcher to show that gametes (he called them "germ cells") are passed on independently of what happens to the organism's body. His Central Dogma, as it became known, was an attack on use-inheritance, the time honoured belief (shared by Darwin among others, cf. Mayr 1982: 687-694, Richards, 1992: 172) that those features of an organism that are most needed and most used will be more frequently inherited. Even after the period of the development of Mendelian genetics, the Central Dogma was not universally accepted by biologists until the middle of this century and the molecular revolution in genetics.
7. The term "Lamarckism" is very ambiguous in the way it is used in biology. Much historical injustice to Lamarck was done by those who called themselves "neo-Lamarckians" in the late nineteenth century. Only two sense of "Lamarckism" are relevant to this paper: *use-inheritance* (see previous note), also known as the inheritance of acquired characteristics; and the belief that novelties evolve to meet the *needs* (sometimes interpreted as the desires) of the organisms when their environment changes. A third form often and more historically accurately referred to is that evolution is progressing to some form of perfection. The charge that evolution of culture is Lamarckian (cf. Gould 1993: 216, 1997: 222) generally refers to use-inheritance (for rebuttals, see Hull 1988: 452-457, Czikó 1995).
8. More recently, Ghiselin, with whom Hull collaborated on the so-called individuality thesis, has reviewed the arguments both have made against the "entification" of replicators, including noting that genes, in the population (or Mendelian) genetics sense, can include *deletions*, that is, the *loss* of a sequence can have population level effects. In his view, this is a *reductio ad absurdum* of Dawkins' genetic reductionism (Ghiselin 1997: 143-148).

9. But it is worth noting that they can be the *product* of the properties of genes. In algebra, sums are linear and additive, while products are non-linear and multiplicative. Non-linear products can be extremely complex, and are so-called because their functions do not result in a straight line on log log graphs.

The Kolmogorov theorem shows that between any two arbitrarily large sets there can be at least one mapping so long as there is an intermediate set of links, an important result for connectionist systems research. These Kolmogorov mappings are non-linear products, and applied to genes and memes the theorem means that while there is no simple reduction from interactive characters to genes/memes a mapping relation does exist, even if it is extremely complex.

10. See Rosenberg's 1994 discussion and clarification of the Hullian entities as they apply to biological processes, and also his discussion of Hull's problem of reductionism. See also Ghiselin 1997.

11. To avoid unnecessary confusion, it should be noted that any number of hierarchies can occur in a single domain like biology or culture. There may be a genetic hierarchy leading to species, but there may also be a hierarchy leading to ecological patterns, and these need not be the same hierarchy. (Eldredge 1989) This figure and the following figures are not intended to represent *the* hierarchy of that domain, but only one of a possible many.

12. However, this does not deny that a selection process based on a mental model of the states of affairs can occur in an individual mind. In terms of figure 2, the memes here are the entities that are selected in a mental environment, that is, what makes sense to the thinker, and which when expressed will become memes in a higher level process [cf. Dennett 1995, chapter 12].

13. One possible exception to this bifurcation is when a meme is a spandrel, that is, a by-product of some *other* meme that *is* selectively favoured, and with which it inevitably must be transmitted (Gould and Lewontin 1979, Gould 1997).

14. This resembles the Marxist-Leninist doctrine of false consciousness in some ways, but with no presumption that any part of society will instantiate a "true consciousness" of social reality.

15. Discussion in Czikó 1995: 140-149.

16. For example, a practice may spread just *because* it is selectively neutral. Junk DNA can be transmitted because it does not generate products that are "visible" to selection. Kimura's theory of neutral DNA shows that biased transmission without selective advantage is a biological reality. And any trait at the interactor level can be selected for or against, in a sense, even if it is not heritable. A blacksmith may do well biologically because of his strength, but that will not (necessarily) be bequeathed to his progeny.

17. As we shall see below, this is not a complete picture; but it captures the initial intuitions of taxonomists.

18. Interestingly, identifying the five or six distinct, but hitherto unrecognized (*cryptic*), species of *A. maculipennis* was accomplished through analysis of their being vectors for *P. falciparum* or not (Cain 1954).

19. I am of the philosophical school of thought that laws and equations merely *describe* dynamic patterns rather than *govern* phenomena (instrumentalism), but that is not germane to this essay. See Rosenberg 1994 for a discussion of instrumentalism and biology.

20. Because the resources required are rather significant, which is an interesting memetic point.

21. This is not a mistake, despite its contradiction to textbook biology. The result was announced in a recent paper (Boerlijst, Bonhoeffer and Nowak 1996).

22. It is worth remembering that Darwinian, or rather synthetic, evolution, is modelled by a number of theories (common descent, natural selection, sexual selection, biogeographic distribution, Mendelian genetics), and should not be considered a single theory on its own.

23. Allopatry is the state of populations living apart from each other (literally "other homeland"), sympatry that of coexisting in the same region ("same homeland"), and parapatry of living in adjacent regions with or without some overlap ("bordering homeland"). When speciation occurs in these states, then it is called allopatric speciation, and so forth. Many now think that parapatric speciation occurs, but the frequency is still at issue.

24. Dobzhansky's concept [1937] of "co-adaptation" (a term initially used by Darwin, I believe) is significant at this point of the argument. If memes at first arise within restricted domains, all they need at this early stage to adapt *to* are the other memes within the deme, or some part of it. Co-adapted memes may play a role in storing memetic variation until the fitness of variants rises to significant levels. Moreover, it would explain why apparently maladaptive memes can persist in a tradition. In the end, the final selection event is extinction, and maladaptive memes may persist because they are fitter within a tradition than on their own, even if they make the lineage phenotype less adaptive overall.

As an example, consider the meme of common property in the fideist traditions such as the Mennonites and the Shakers. This meme was a core belief and tradition in these communities, and was well adapted to the rest of the memes shared by the communities, but it was maladaptive during the most aggressive period of the rise of modern industrial capitalism, and these communities eventually faded away.

25. An early shot at proto-sociobiological notions, although I think Bradley underestimates how much biology affects one's *place* in a culture. Imagine the role of a Chinese child growing up in Victorian England.

26. Random with respect to the selection process, that is.

27. Phonemes, words, syntactical structures, etc.

28. Funding for research is peer reviewed, even if it derives from governments, and so the primary economic resource is standing in that community, cf. Hull 1988c.
29. Supporting physical entities of the code.
30. Genes also include and require RNA of various kinds, so even this generalization is not absolute.
31. At least, until artificial intelligences become a reality.
32. Interestingly, Hamming Distance was first formulated in the context of information theory, and adapted for use in genetics after the molecular revolution. See Gabora forthcoming for a treatment of Hamming Distance in memetics, but one that I think is overly reductionist.
33. Cladistic reconstructions rely on an absence of reticulation, and so should be used with care in the memetic context. Cf. Wiley et al 1991.

MEMES AIN'T (JUST) IN THE HEAD
A Commentary on Gatherer's paper: Why the 'Thought Contagion'
Metaphor is Retarding the Progress of Memetics"

By

John Wilkins

wilkins@wehi.edu.au

PO Box 542, Somerville 3912, Australia.

In a famous quip, Hilary Putnam once stated that "meanings just ain't in the head". It seems that the field of memetics and memetic theory is developing a couple of deep divisions: one between those who think of memes as genes and those who think of them as germs and the other between those who think memes are in the head, and those who think they ain't. In this essay I shall deal with these questions, but not attempt to further define what I think a meme is, which I have already done (Wilkins 1998a), based upon the cybernetic notion of an evolutionary gene of G. C. Williams (1966) and the Shannon-Weaver concept of a message:

A meme is the least unit of sociocultural information relative to a selection process that has favourable or unfavourable selection bias that exceeds its endogenous tendency to change. Derek Gatherer (1998) has written a provocative and interesting paper attacking the "thought contagion" notion of memetics and claims that no population model of memes is possible. He follows Benzon's (1996) earlier approach of locating memes in the overt behaviour and artifacts of culture. He and Benzon are both anti-head memeticists, and I suspect that they prefer to see memes as Mendelian genes, observed by their effects. His target is Aaron Lynch's (1998) pro-germs and pro-head view (overlooking here some of Lynch's subtleties), derived from the later views of Dawkins (1982, 1993).

Gatherer notices a shift in the meme definitions provided by Richard Dawkins, and calls them *Dawkins A*, and *Dawkins B*:

Dawkins A: '...a unit of cultural transmission, or a unit of imitation.' (Dawkins 1976, p.206); 'Examples of memes are tunes, ideas, catch-phrases, clothes fashions, ways of making pots or of building arches' (Dawkins 1976, p.206); 'Popular songs and stiletto heels are examples. Others, such as the Jewish religious laws...' (Dawkins 1976, p.209); 'Perhaps we could regard an organised church, with its architecture, rituals, laws, music, art and written tradition, as a co-adapted stable set of mutually-assisting memes.' (Dawkins 1976, p.212); 'Memes for blind faith have their own ruthless ways of propagating themselves.' (Dawkins 1976, p.213).

Dawkins B: (referring to the original Dawkins A definition, above) '...I was insufficiently clear about the distinction between the meme itself, as replicator, on the one hand, and its 'phenotypic effects' or 'meme products' on the other. A meme should be regarded as a unit of information residing in a brain..... It has a definite structure, realized in whatever physical medium the brain uses for storing information....I would want to regard it as physically residing in the brain.' (Dawkins 1982, p.109); 'The phenotypic effects of a meme may be in the form of words, music, visual images, styles of clothes, facial or hand gestures.....' (Dawkins 1982, p.109).

The different approaches I call the "genes" and the "germs" view of memes are based respectively on Dawkins B and Dawkins A. The genes view seeks to understand memes as analogous to the information units of selection and the causes of (in this case, sociocultural) evolution. Memes are units of cultural heredity, just as genes are units of biological heredity on this approach. The germs view seeks to explain the epidemiological spread of memes, like viruses through a population. It does not explicitly concern itself with selection or evolution. Gatherer rejects Dawkins B in favour of the following definition of a meme, which he is revising from William Benzon's (1996) definition:

***Meme:** an observable cultural phenomenon, such as a behaviour, artefact or an objective piece of information, which is copied, imitated or learned, and thus may replicate within a cultural system. Objective information includes instructions, norms, rules, institutions and social practices provided they are observable.*

While I agree with much of Gatherer's criticism and many of his conclusions, especially of the thought contagion approach to memetics, I am moved to argue against his major claim that memes aren't to be located in the heads of individuals and to assert the possibility and even immediate attainability of a populational memetics. I do this from a philosophical perspective, and philosophers are notoriously poor at prescribing the best routes for science to take, particularly in the area of methodology, so I won't do that. Instead I'll do the traditional philosophical job of armchair criticism, and I expect to be taken in that light. Mostly, I will reject the inference from a specific denial to a general one, the move I call "simply because". My view could be seen as a compatibilism between both the germs/genes division and between the in-head/out-of-head division. Such is the wishy-washyness of being a philosopher.

Objection 1 - Over generalisation. My first objection is that he has overgeneralised. Simply because we can now have no population memetics, or because it fails in Gatherer's aptly chosen example of the Windsor knot, it does not follow that we cannot have it in any case. Gatherer wishes to extend the fact that we cannot easily, if at all, identify the knowing of "how to tie a Windsor knot" with the act of "tying a Windsor knot", and we can only say with certainty how many actual Windsor knots there are in a population. Again, just because in some cases we cannot say who "has" the Windsor knot meme; it is not thereby true that we can never know who has memes. Some memes are identifiable, and in quite specific terms. I have instanced the memes of scientific theories (Wilkins 1998a, 1998b) but I also expect that there will be a number of other examples of the attitudinal kind usually found in social surveys. These can be operationally defined by the process of iterative refinement exemplified by Grounded Theory in health research (cf Wilkins 1998b).

Objection 2 - Over reliance on instrumentalism. Simply because we cannot assay memes except through behaviour, which is quite true, it does not follow that memes of a mental kind are simply hypothetically postulated entities (or HYPEs). To argue this is to confuse information with its expression, the cause with the effect. It is true that we reason backwards from phenomenon to mechanism in science, but HYPEs have this habit of becoming observable, measurable, entities in their own right. Electrons are a case in point (Hacking 1983). Once the very model of a HYPE, and treated as an instrumental theoretical notion, useful for calculating but not much else, electrons are now routinely manipulated; sprayed, bathed and no doubt washed over objects for

our own purposes. Hacking suggested the Higgs Boson as an echt HYPE, but almost as soon as he did, it was observed. The process of natural selection itself has moved from being a hypothetical process to being an observed and repeatably manipulated phenomenon (Bell 1992). So the "simply because" here fails to support the blanket conclusion of the impossibility of mental memes.

However, the engram proposal is, I agree, quite wrong. The relation between neural net structures and dynamics on the one hand and cultural structures and dynamics on the other is many:many, and represents a Kolmogorov mapping between domains of over determination in both directions (figure 1). It is unhelpful to try to identify memes in terms of the neural structures that encodes them, because memes are multiply realized and neural nodes are involved in realising more than one meme, at least most of the time. While a single region of a brain may be involved in the storage and activation of a given concept or word, it does not follow that every brain does it in quite this way. Similar issues apply to genes and traits. While there happens to be a strong conservation of many structural and regulatory genes, such as Hox which is implicated in the expression of appendages, the variety of appendages so generated are very different. And not all appendages involve Hox or its orthologs. The "leg" genes are a heterogeneous set across lineages, what in taxonomy is called a polythetic set.

Figure 1. A Kolmogorov mapping of memes

Objection 3 - Memes are units of information. Although I agree with Gatherer that memes are not beliefs (in philosophy this is known as the distinction between propositions and doxastic attitudes to propositions), I disagree with him that memes are not sequences of information (and with Lynch 1998 that memes are single units; it is naive in the extreme to think that propositions are simple entities, in defiance of all logical and linguistic analysis since Frege). Memes are meaningful, semantic, information transmitted as a message from a source to a receiver. Note that semantic information is a notion that differs from the Shannon-Weaver concept of information, which is a signal-relative notion that may, or may not, have semantic content. The most "information-bearing" signal is one that is entirely random under Shannon-Weaver, because it takes a minimum message equal to the actual message to transmit it. Any semantic message is still a Shannon-Weaver message, but not all Shannon-Weaver messages are semantic messages. It follows that memes are messages, of the semantic variety.

Any message may, relative to an encoding protocol, be represented as a bit string, and so once we have such a conventional protocol (a formal "language" of the minimum kind) we can: Identify empirically, through census techniques, what the relative sizes and durations of memes are;

Deliver a populational and cluster analysis and measure changes in both instances and message structure over time

Relate differing homologous versions of memes; in other words, classify memes according to common ancestry (subject to the difficulties of such phyletic reconstructions and taxonomies caused by lack of information and loss of information due to homoplasies and reticulations in the evolutionary tree).

I shall say more on the structure of memetic information below. However, it must be noted that the observation of "objective" behaviours suffers exactly the same problems as semantic memes: we have no easy way to identify them, classify and relate them (i.e., distinguish homologies from analogies) and measure them purely on the external, observable properties and structures alone. This is because we need to have semantic information about them before we can do any of these things. Again, I shall say more about this shortly.

Gatherer rightly makes much of the notion of variations in memes in response to Lynch's naive conception of "mnemons" (which, in the end, are just the "propositions" of late medieval Platonic philosophy). This point is well-made: anything that can be expressed as a sentence cannot be a unitary semantic entity. The sentence, "There is(are) <n> god(s)" is a complex structure with place holders for variables, as is the sentence, "Napoleon died in <year date>", and an infinite number of sentence tokens can be generated from the primitive relations (predicates) used to construct it. Using such primitive operators of the conventional natural language as "... died in ...", "some definite number of ...", along with the natural quantifiers "there exists" and cognates, and proper names and the natural numbers, etc, one can regenerate a literal infinity of statements from a very few, indeed quite small, number of stored and retrievable linguistic structures. If Chomsky's Transformational Grammar or something like it has any validity as a schematic for the neurology of language (cf Pinker 1994) then there is no real objection to memes being in the head in the sense that we can store a certain number of these constructions, and yet generate as many as needed on demand. Gatherer's objection would hold if we had to store all possible memes instead of only these variables and connectives. Instead, these semantic entities and their relations can be represented as a hypercube of however many dimensions there are particles. A given meme is therefore a well-formed coordinate in that resulting space. We can store some number of coordinates without having to store all of them, and yet be able to traverse this semantic space if it becomes important.

It's not up to philosophers to conjecture about mechanisms - that should be left to working researchers like Gatherer who use experiment and empirical data collection. However, I can make one suggestion: where memes might be located. If memes are messages, then they are entirely relative to considerations of encoding protocols, language (and logic) forms, and evaluative attitudes that determine recognition and responses. The meme therefore consists in the relationship between the neurological states and resulting behaviours of individuals and these contextual abstractions. This is illustrated in figure 2.

Figure 2. Culturally significant transmits as a subset of an individual's outputs

The output of the memes in an individual might be behaviours (Windsor knot tying), or artifacts (Windsor knots), or both. But a one-year old (let's call him Charlie) playing with Daddy's ties might randomly create the topology we call a Windsor knot, exhibiting neither the meme in thought, behaviour or in artifact. What counts here is the mental state - I hesitate to call it the intention, but at any rate the knowledge and understanding - its openness to inspection, the output, and the context... and above all the transmissibility of the result to others.

We have two entirely different issues here. What kind of entity, on the first hand, is a meme? On the other hand, what method and heuristic can we use to locate, measure, differentiate and model memes? Gatherer wishes to follow Benzon and locate them in physical structures, not of neurons and glial cells, but of artifacts and the actual behaviour patterns of cultures. Only these are measurable and objective. We can see a Windsor knot, and we can watch it being tied. I have two objections to the Benzon-Gatherer "External Meme" thesis, but in so doing I do not wish to reassert the truth of Dawkins B - the thesis that memes are just units of information residing in brains. They are, I aver, informational structures, and they do reside in brains a lot of the time, but as I have argued before (Wilkins 1998a), they also often exist in the cultural relations between brains, and may not even exist in any brains at all at a time or ever.

Moreover, I expect that what goes on inside brains will sometimes be, not memes, but meme-like; call them "memoids" after Dawkins' term for design-like objects, "designoids" (Dawkins 1996). They will resemble memes in that they appear to be semantic structures encoded in neural networks, but their selection within the brain will often be hit-or-miss and inconsistent, despite Dennett's thesis of a strict internal selection (Dennett 1991, chapter 8). What counts isn't so much the selection process inside the head as the one outside, and that requires transmission.

The first objection to the exclusive External Meme thesis is again a "simply because" objection. Just because we can locate, measure, differentiate and model something is not reason to think that what we (now, or even in principle) cannot is nonexistent or nonsensical. This was the deep error of Skinnerian behaviourism, a holdover of old positivism, and it made of an epistemic limitation an ontological virtue. Although I am sure that neither Gatherer nor Benzon is a positivist, this is still an all-too-common error in science. While we may narrow down the search space of alternative HYPEs in this way, and Occam's Razor may seem to give weight to that approach, the history of science has shown (not least with the notion of a "gene") that it often leads to error and failure of research. We had better not kid ourselves that if we can't see it, it can't affect us, like kids hiding from monsters under the blanket at night.

My second objection is related also to the faults of Skinnerian behaviourism - the denial of what we are pretty sure is real and significant. Skinner denied the reality of psychological states - the External Meme thesis seems to be predicated on the denial of concepts. Questions raised by Gatherer of what in philosophy is called the K-K principle (if we know, we must know that we know, ad infinitum) aside, surely if I know how to tie a Windsor knot, some causally relevant structure exists inside my brain? And it must be one that satisfies the relevant semantic relation to the culture that defines Windsor knots and which therefore makes it "about" Windsor knots.

Now I am not here trying to revivify the extreme reductionism of engrams, the one meme-one engram theory, if ever it was seriously proposed. Memes are, in my perspective, multiply realized and multiply instantiated by neural net structures (as neural nets are wont to do). The view proposed by Delius (1991) that a meme will have a single locatable and observable structure ("a constellation of activated neuronal synapses") is not viable. In philosophical jargon, memes are not supervenient properties, for a property that supervenes on a physical system must be identical if the physical system is. The same meme might be realized in a number of physical systems, consistently with supervenience, but identical or very closely similar neural nets might encode quite distinct memes. This is because memes are relations in semantic space, not neurological space.

Let me explain by returning to Charlie's Windsor knot accident. If his knot matches exactly that of the very metre of Windsor knots, Prince Phillip's butler, when none of the "normal" intentions or concepts are possible, then the "Windsor knot" that results is only an accident. We would not call it a cultural artifact if the wind "tied" a bullrush in that knot, and we wouldn't here, except in an honorary sense. There is a continuum of intentionality and "aboutness" from the bullrush to Prince Phillip's butler. There is no absolute point at which mere topology makes that meme, and the resemblance the bullrush has for an observer is merely subjective - it looks like one so the observer, who has learned about Windsor knots, "reads" that topology that way.

But what makes that knot a Windsor knot is the fact that it results from the transmission from one agent to another (with, I suppose, some Urbutler in the House of Windsor as the Last Common Ancestor) of the "how-to" of Windsor knot tying. The more-or-less formal algorithm is what gets transmitted. This constitutes a message, an abstract array of symbols that are interpreted in the context of a consensual, or conventional, language and set of behaviours and standards. So, we cannot really say that it is the physical knot, nor even the tying behaviour, that is the meme, at least not without the interpretive context and semantic structures of a culture.

So, can we make memetics an operational science at all? I believe we can, and the reason is that in many cases we already have just the semantic apparatus needed to identify memes, and that resolving memes is a matter of resolving them enough to identify them. Goodenough and Dawkins (1994) had no trouble identifying instances of the St Jude Chain letter, even across cultural divides, and with a suitable knowledge, say, of Spanish, one could identify instances of it across languages. For most situations being investigated, seeing a Windsor knot being tied is evidence enough that there is a Windsor knot meme about. Eccentric examples of multiple personalities and other exotic exemplars are not enough to shake our confidence that there are memes, that usually people have them, and that we can count them well enough to model them in a populational, statistical, manner.

A general observation: Gatherer rightly worries about the academic respectability of memetics, just as serious researchers have worried about, say, the Gaia hypothesis - which is only now coming into serious contention, even by such respectable academics as William Hamilton (Hamilton and Lenton 1998) (of Hamiltonian inclusive fitness) - or complexity theory. The debasement of memetics by quick and easy metaphors and popularised science to serve metaphysical agendas and political ideologies, with which we are all too familiar, is just the latest instance of serious evolutionary theory being perverted in that way, beginning with Spencer and the Edinburgh radicals of the 1840s, through social "Darwinism", "cultural evolution" theories, eugenics positive and negative, and so forth.

I'm of the view that the term memetics is now a liability, at least until it can be rehabilitated with some actual research instead of conjecture and anecdote. I tend to think of this whole field as cultural Darwinism, stressing the essentially amoral and nonevaluative dynamics of culture, and drawing no conclusions about what should be transmitted, instead seeking to know why things are transmitted, and adopting the generally pluralistic nature of Darwinism.

In Darwinism proper not everything must be explained in terms of its adaptation - Sewall Wright is centrally installed in modern synthetic Darwinism. Memetics is analogous to genetics not selection, and it is a subdiscipline of cultural Darwinism dealing with the evidence for causal factors that create the behaviours and artifacts we see and their rates of transmission.

As soon as we use a metaphor like "thought contagion" we are insert all kinds of socially-weighted evaluations associated with the terms "pathogen", "parasite", "disease" and the like, none of which play a useful role in a Darwinian model of any kind of change. The arbitrary difference between a predator and a parasite is the rate at which it kills its host, but we tend to think of parasites as, well, parasitic and therefore nasty, and predators as having a more noble ecological role. But in the end there is only selection and drift, and I refer readers to Paul Ewald's excellent treatment of this topic (Ewald 1994) for a fuller discussion.

Acknowledgements

Bill Benzon and Derek Gatherer have engaged me in electronic conversation on this topic over a period of time. Benzon was good enough to send me a selection of his papers, and Prof Juan Delius a copy of his paper, which makes my present disagreement with them an act of ingratitude. Despite my conversations with them and many others, including Mark Mills, for which I am continually grateful, nobody is responsible for the errors contained herein but me.

ON CHOOSING TO EVOLVE: STRATEGIES WITHOUT A STRATEGIST

A Commentary on Rose's Paper: "Controversies in Meme Theory"

By

John Wilkins

wilkins@wehi.edu.au

PO Box 542, Somerville 3912, Australia.

In his 1974 paper Michael Ghiselin wrote that while there were evolutionary strategies, the only evolutionary strategists were the biologists studying evolution. Nick Rose (1998) has raised several interesting problems not only for memetics but evolutionary thinking in general. To avoid the Scylla of Lamarckism, he has chosen instead the Charybdis of denying the bleeding obvious - that intentions play a part in evolution. Before anyone accuses me of deserting the Darwinian fold for Lamarck, let me explain.

It seems that the reason Rose takes this tack and follows Dennett's attack on the Cartesian Theatre of the Self (Dennett 1992, 1995) is that if we admit the role of intentions into evolution, we end up with some kind of Piagetian Lamarckism (Piaget 1979) and lose the strength of the blind watchmaker schema - evolution through natural selection (plus sundry other theoretical bits like drift). Must it be so? Are intentions really that dangerous?

Usually when the charge of Lamarckism is raised, the spectre of clairvoyance lies not too far beneath it (Hull 1988). We choose to solve problems, we seek solutions, we adapt by learning, not by random variation and selective retention (Campbell 1960, Popper 1972). If we take this approach, then evolutionary explanations of memes are redundant and indeed otiose. Better to deny that we can choose and control memes at all. If folk psychology admits a causal role for intentions, so much the worse for folk psychology. I think this is wrong. We can have our memetic cake and eat intentions too, if we recast matters just a bit.

The lion, contra Wittgenstein (1968) can surely be understood to have intentions to catch the gazelle. Just as surely, if a gazelle thinks and intends at all, it intends not to be caught by the lion. Yet, the outcome is an evolutionary one, and purely Darwinian. How can this be? Didn't we just stipulate that intentions make Darwinism otiose? Well, there is an obvious difference between intending to solve a problem and actually achieving the solution. The problem of induction, and its heirs like Nelson's 'Grue' Paradox (Goodman 1973), shows that intentions are not endowed with magical clairvoyance. After all, we humans have intentions that pave many roads with varying destinations. Selection operates on outcomes not the provenance of variations.

Having intentions and being able to learn are at once both biasing effects on the selective landscape and also adaptations in themselves - one reason why we do have the cognitive faculties we do is that it broadens the range of adaptation. If we can learn, we can deal with challenges without waiting for mutations, but once we have the novel lifestyle, selection can catch up as soon as more cost-effective instinctual behaviours appear genetically. This is called the Baldwin Effect (Belew and Mitchell 1996, Turney et al. 1996) and is perfectly Darwinian. Learning deforms the fitness landscape.

Ignore, for a moment, the supposed psychic powers of intentionality and consider instead trait U. This trait permits an organism to deal more effectively with its environment than non-U organisms can. It is not perfect, because the environment can always bowl a spin ball, but it does bias the odds in favour of U-bearers as opposed to non-U's. It will obviously spread through its deme so long as selection is stronger than drift. There's nothing too problematic about this. Now, substitute 'intention' for U, and see if it makes the slightest difference to the Darwinian nature of the model. I submit that this does not. So, how does this biological argument bear on memes? If memes are selected for or against intentionally on the basis of prior experience and propensities to estimate the likely success of a given strategy, that will deform the fitness landscape for those memes and meme-bearers. We pick those memes that we estimate will succeed. But no matter how good we are at picking strategies, our intentions merely bias, they do not determine the outcomes. Our social ecology is not totally plastic any more than the biological ecology is. We cannot, on pain of sinning against St. David Hume, predict with complete accuracy what comes our way next.

The strategies we inherit are not good because we rationally analysed them. Indeed, we inherit them because they are good ones, for whatever reason. No grand Cartesian General planned them, and the presence or absence of a minor strategist does not impugn evolutionary explanation. Quine once wrote (Quine 1969) that "*creatures inveterately wrong in their inductions have a pathetic but praiseworthy tendency to die before reproducing their kind*" (p 126). Social agents that are ordinarily wrong about good ways to proceed tend not to have much influence or leave many intellectual descendants (the praiseworthiness is left as a judgment for the reader). So, we had better be good at choosing our memes if we want to have any influence.

However, come the next revolution, many of our strategies may find themselves first against the wall. Selection reigns in social games as much as in the struggle for existence. If wishes were horses, then beggars would ride. No clairvoyance, just good old trial and error. I believe that any Lamarckian process of evolution can be reformulated as a Darwinian process. The difference is one of rate, degree of novelty, and fidelity of transmission (Fisher 1930). Dennett (1995) notes that memetic selection occurs first in the head, then locally and finally more broadly (Cziko 1995, Wilkins 1998). But although the selective filters of our mind are not a Cartesian Self, that there exists an intentional social agent is silly to deny. It is bounded by the extent of direct control of our body by the central nervous system. To agree with Wittgenstein this time, the best model of the human soul is the human face.

An intending self is the social agent, and it has some control over the kinds of memes it hosts, not unlike the limited control our immune system has over the sorts of microorganisms that a body hosts. Cognitive structures and processes behave something like the immune system. Good immune systems, and good memetic selection patterns, get more copies of themselves passed on. It may make it harder to model things, but we have to live with intentions in memetics.
